EANM'17

Annual Congress of the
European Association of Nuclear Medicine
October 21 – 25, 2017
Vienna, Austria

Abstracts

This supplement was not sponsored by outside commercial interests. It was funded entirely by the association's own resources

Dear colleagues, dear friends,

It is with great pleasure that the European Association of Nuclear Medicine welcomes you to its 30th Annual Congress in Vienna, Austria.

Over the 30 years since our first Congress, nuclear medicine has made significant strides. Overall usage of nuclear medicine procedures is expanding rapidly, and this trend is especially evident with respect to new imaging technologies. We can affirm that the revolution of tomographic hybrid imaging within the nuclear medicine landscape is now a matter of fact, spurred by evidence-based medicine. Our discipline's next step is the integration of genome-specific targeted theranostics, utilising in vivo whole-body assessment of tissue morphology, physiology and biochemistry. The ultimate goal is to design personalised, super-selective therapies and to identify more precise means of monitoring response to treatment in routine clinical practice.

The annual EANM Congress has become the world-leading meeting in nuclear medicine. In order to maintain the high level of excellence of our Congress, the 2017 meeting will build on the traditions that are highly appreciated by all attendees, with expansion of the newer features introduced by the former Congress Chair. A specific educational track, implemented in collaboration with the European School of Multimodality Imaging and Therapy, will include up-to-date Teaching Sessions, enriched by Pitfalls & Artefacts and Continuous Medical Education (CME) sessions. In all these "active learning" sessions, attendees will have the possibility to enhance their knowledge of multimodality imaging. With similar pedagogic intent, numerous multidisciplinary joint symposia organised by EANM Committees and our sister societies will offer an integrative approach to various topics relevant to the state of the art in our discipline. On the occasion of its 30th anniversary, our Congress will feature two new events (as well as a very big surprise). First, a panel display of the best regional posters will illustrate its global scope. Second, a specific Presidential Session will be dedicated to the best-ranked papers from the under-30s. Our young colleagues represent the future of our discipline and should begin to shape their knowledge in ways that will contribute to a brighter tomorrow for the whole nuclear medicine community!

All these learning sessions will not impact adversely on the predominant role of the entire Congress, which is to enable the presentation of oral papers and posters about the latest achievements in clinical nuclear medicine, science and technology. On the contrary, the Rapid Fire sessions, for example, will be enriched. The spirit of such sessions is to draw attention to the most highly rated abstracts in specific areas: a panel of top-level presentations is followed by extensive discussions, providing attendees with an integrated and coherent view on a wide variety of topics. Furthermore, featured oral sessions with one invited speaker in combination with "regular" presentations will broaden the perspectives on all topics. The now well-established tracks M2M – Molecule to Man (basic and translational science) and Do.MoRe (radionuclide therapy and dosimetry) will promote high-quality research through interaction between basic and translational clinical scientists and allow presentation of the latest achievements and developments in the fields of clinical molecular imaging and nuclear medicine therapy. During the plenary lectures, distinguished speakers will address state of the art science together with new developments in clinical and allied sciences, covering a broad range of topics with the goal of promoting the best possible care for our patients. At the end of the meeting, two eminent lecturers, Prof. Stefano Fanti from Bologna, Italy and Prof. Clemens Decristoforo from Innsbruck, Austria will present the traditional Highlights Lecture.

The Congress will take place in Vienna, Austria, where the EANM Executive Office is also based. The city – located in the heart of Europe, on the banks of the river Danube – is world famous for its imperial heritage, its cultural attractions and its culinary highlights. To quote the slogan of the city: Vienna awaits you!

For all these reasons, I cordially invite you to the EANM'17 Congress and to actively participate in our 30th anniversary. Meet and interact with friends and colleagues from all over the world, break away from the daily routine and enjoy Vienna's hospitality.

Francesco Giammarile,
EANM Congress Chair 2017-2019

Saturday, October 21, 2017

Time	Hall A,B,C	Meeting Room	Hall E1	Hall E2	Hall F2	Hall K1	Hall K2	Hall G1	Hall G2
09:00 - 09:30					**Pre-Symposium 1** Physics/Dosimetry	**Pre-Symposium 2** Oncology/ Radionuclide Therapy/EWALT	**Pre-Symposium 3** Dosimetry/ Radiation Protection	**Pre-Symposium 4** Neuroimaging/ Drug Development/ Radiopharmacy	**Pre-Symposium 5** Radiopharmacy
09:30 - 10:00					Monte Carlo Simulation / Image Reconstruction – Part I	Integrated Approach for the Diagnosis and Treatment of Primary Liver Tumors (HCC & CCC)	Clinical Introduction of New Radiotherapeutics: Challenges and Opportunities	Tau Imaging in Humans	Validation & Risk Assessment
10:00 - 10:30									
10:30 - 11:00									
11:00 - 11:30		**EANM Advisory Council Meeting**							
11:30 - 12:00									
12:00 - 12:30									
12:30 - 13:00									
13:00 - 13:30					**Pre-Symposium 6** Physics/Dosimetry	**Pre-Symposium 7** Oncology/ Radionuclide Therapy	**Pre-Symposium 8** Drug Development/ Neuroimaging	**Pre-Symposium 9** Translational Molecular Imaging & Therapy/ Radiopharmacy/ Drug Development	**Pre-Symposium 10** Cardiovascular/ Inflammation & Infection
13:30 - 14:00					Monte Carlo Simulation / Image Reconstruction – Part II	PET Imaging for Response Assessment of Immune Modulation and Therapy	The Contribution of Imaging in the Exploration of Autism		Role of Nuclear Medicine in the Detection of Infection of Cardiac Prosthesis or Devices
14:00 - 14:30		**EANM Delegates Assembly**						Bioorthogonal and Click Chemistry for Molecular Imaging	
14:30 - 15:00									
15:00 - 15:30									
15:30 - 16:00									
16:00 - 16:30			**EANM Members Assembly** (first call 16:00)						
16:30 - 17:00									
17:00 - 17:30									
17:30 - 18:00									
18:00 - 18:30									
19:30 - 20:30	**EANM Opening Ceremony**								

Sunday, October 22, 2017

Time	Hall A	Hall B	Hall C	Hall E1	Hall E2	Hall F1	Hall F2	Hall K	Hall G1	Hall G2	e-Posters
08:00 - 08:30	*101* **CME 1** Physics	*102* **Joint Symposium 1** Oncology/ESTRO	**Technologists' Opening**	*104* **Do.MoRe**	*105* **M2M**	*106* **Pitfalls & Artefacts 1 - ICC***		*108* **Committee Symposium 1**		*110* **Joint Symposium 16**	
08:30 - 09:00	Challenges and Solutions for MR-Based Attenuation Correction of PET	Molecular PET Imaging in Adaptive Radiotherapy: Focus on Current Trends, Challenges and Solutions	*103* **CTE 1** Technologists/ SNMMI	Radionuclide Therapy - Miscellaneous (RIT & Bone Palliation)	α-Therapy	Neuroimaging/ Physics/EFOMP		Inflammation & Infection/ Drug Development		Neuroimaging/JSNM	**e-Poster Walks**
09:00 - 09:30			Quality Control and Protocol Standardisation - Tech Guide Launch			Pitfalls and Artefacts in Visual vs. Quantitative Reading		68Ga-Tracers for Infection Imaging		Educating Referring Physicians and Recognising Their Needs	E-PW01, E-PW02, E-PW03
09:30 - 10:00											
10:00 - 10:30	*201* **Plenary 1 incl. Marie Curie Lecture**		*203* **IN HALL A**								
10:30 - 11:00	Theranostic Developments for Prostate Cancer		**Plenary 1 incl. Marie Curie Lecture** Theranostic Developments for Prostate Cancer								
11:00 - 11:30											
11:30 - 12:00	*301* **CME 2** Inflammation & Infection/ESVS	*302* **Joint Symposium 2** Radionuclide Therapy/ENETS	*303* **CTE 2** Interactive Technologists/EARL	*304* **Do.MoRe**	*305* **M2M**	*306* **Pitfalls & Artefacts 2 - ICC***	*307* **Clinical Oncology**		*309* **Do.MoRe - Featured**	*310* **Conventional & Specialised Nuclear Medicine**	
12:00 - 12:30	Vascular Graft Infection	Establishing a Position for PRRT in the Multidisciplinary Treatment of NETs	Technologist Role in Research and EARL Accreditation	Modeling & Radiobiology	Antibodies	Cardiovascular	We Want a New Drug		Photodynamic Therapy & Molecular Imaging – The Perfect Couple?	Benign Thyroid & Parathyroid Diseases	
12:30 - 13:00						Pitfalls and Artefacts with CZT Cameras					
13:00 - 14:30						**EANM Young Daily Forum**	**Industry Sponsored Symposium**	**Industry Sponsored Symposium**	**Industry Sponsored Symposium**		
14:30 - 15:00	*401* **CME 3** Cardiovascular	*402* **Joint Symposium 3** Thyroid/ETA-CRN	*403a* **Mini Course 1** Technologists	*404* **Do.MoRe**	*405* **M2M**	*406* **Teaching Session 1 - ICC***	*407* **Clinical Oncology**		*409* **Neurosciences**	*410* **Conventional & Specialised Nuclear Medicine**	
15:00 - 15:30	How to Perform Myocardial Perfusion Imaging According to EANM Recommendations	Update Thyroid Cancer Beyond I-131	Cardiology: Pitfalls & Artefacts	Radiopeptides for Therapy	New Targets	Applied Cross Sectional Anatomy and Correlative Imaging – Head and Neck	Rapid Fire Session Prostate		Imaging Amyloid and Amyloidogenesis	Pulmonology & Nephrourology	
15:30 - 16:00											
16:00 - 16:30			*403b* **Mini Course 2** Technologists/ Inflammation & Infection								
16:30 - 17:00	*501* **CME 4** Oncology	*502* **Joint Symposium 4** Dosimetry/Radiation Protection/ICRP/ICRU	Inflammation: Pitfalls & Artefacts	*504* **Do.MoRe**	*505* **M2M - Featured**	*506* **Teaching Session 2 - ICC***	*507* **Clinical Oncology**	*508* **Cardiovascular System**	*509* **Neurosciences**	*510* **Conventional & Specialised Nuclear Medicine**	
17:00 - 17:30	PET in Multiple Myeloma	Radiological Protection for Patients Receiving Radiopharmaceutical Therapy	*403c* **Mini Course 3** Technologists **Interactive**	SPECT Quantification	Combination Therapies	Applied Cross Sectional Anatomy and Correlative Imaging – Foot and Ankle	NET, a Classic!	Myocardial Function, Metabolism & Perfusion - From Preclinical to Clinical Practice	Imaging Neurotransmission Systems in Parkinson	Paediatrics	
17:30 - 18:00			Bone and Joint: Pitfalls & Artefacts								

Plenary Sessions | CME Sessions | Joint/Special/Committee Symposia | Technologist Sessions | Do.MoRe | M2M | Pitfalls & Artefacts / Teaching Sessions (*ICC = Interactive Clinical Cases) | Clinical Oncology Sessions | Cardiovascular System | Neurosciences | Conventional & Specialised Nuclear Medicine

Oral Sessions

PS1   Saturday, October 21, 2017, 09:00 - 12:00, Hall F2

Pre-Congress Symposium 1 - Monte Carlo Simulation / Image Reconstruction – Part I

PS01
SPECT/(CT) Quantitative Reconstruction Techniques
R. van Holen; Ghent University, Department of Electronics and Information Systems, Ghent, BELGIUM

PS02
Motion Detection and Correction in PET/CT and PET/MRI
K. Thielemans; University College London, UCL Hospital, Institute of Nuclear Medicine, London, UNITED KINGDOM.

PS05
Basics and Principles of 4D PET Image Reconstruction
A. Reader; King's College London, Biomedical Engineering Department, London, UNITED KINGDOM.

PS06
TOF Reconstruction Methods and Benefits for Clinical Imaging
J. Karp; University of Pennsylvania school of Arts and Sciences, Department of Radiology, Philadelphia, UNITED STATES OF AMERICA.

PS07
A Focus on MLAAPET Reconstruction
R. Boellaard; University of Groningen, Center for Medical Imaging, Groningen, NETHERLANDS.

PS2   Saturday, October 21, 2017, 09:00 - 12:00, Hall K1

Pre-Congress Symposium 2 - EANM/EWALT: Integrated Approach for the Diagnosis and Treatment of Primary Liver Tumours (HCC & CCC)

PS08
Pathological Diagnosis and Molecular Predictors in Primary Liver Tumours
L. Rubbia-Brandt; Hôpitaux Universitaires de Genève, Service de Pathologie Clinique, Geneva, SWITZERLAND.

PS09
Hepatologist Perspective on Primary Liver Tumours from Diagnosis to Prevention
Y. Kallis; Barts and the London School of Medicine and Dentistry, Queen Mary University London, London, UNITED KINGDOM..

PS10
Cross Sectional Imaging in HCC and CCC Including Novel MRI Techniques for Early Detection
M. Ronot; Department of Radiology, Beaujon Hospital, AP-HP, Paris, FRANCE

PS11
Molecular Imaging with FDG and Non-FDG PET Tracers
J.-N. Talbot; Hospital Tenon, AP-HP & Université P&M Curie, Paris, FRANCE.

PS13
Locoregional Treatment in Primary Liver Tumours
L. A. Solbiati; Department of Biomedical Sciences - Humanitas University, Milan, ITALY.

PS14
Innovative Surgical Approaches in HCC and CCC
G. Torzilli; Humanitas University, School of Medicine, Humanitas Research Hospital, IRCCS , Milan, ITALY.

PS15
Update on Oncological Management of Cholangiocarcinoma and HCC Including Novel Agent
N. Starling; The Royal Marsden , London, UNITED KINGDOM.

PS16
Role of Transarterial Radioembolisation in Primary Liver Tumours
S. Ezzedin; Universitätsklinikum des Saarlandes, Klinik für Nuklearmedizin, Homburg, GERMANY.

PS3   Saturday, October 21, 2017, 09:00 - 12:00, Hall K2

Pre-Congress Symposium 3 - Clinical Introduction of New Radiotherapeutics: Challenges and Opportunities

PS17
Introduction
G. Flux; Royal Marsden NHS Trust & Institute of Cancer Research, London, UNITED KINGDOM.

PS18
Phosphorous-32 Microparticles
A. Soman; Oncosil medical Ltd, Sydney, AUSTRALIA.

PS19
Holmium-166 Microspheres
F. Nijsen; Quirem Medical, Groningen, NETHERLANDS.

PS20
Y-90 Glass Microspheres
T. Mauxion; BTG, Nantes, FRANCE.

PS21
Alpha Therapy with Radium-223 and Thorium-227
J. Gay; Bayer Healthcare, Berlin, GERMANY.

PS23
Treatment of NHL with Lutetium-177 Labelled Anti-CD37 Antibodies
J. Dahle; Nordic Nanovector, Oslo, NORWAY.

PS24

Lutetium-177 Peptides and Antibodies

M. Mariani; Advanced Accelerator Applications, Saint-Genis-Pouilly, FRANCE.

PS25

Copper Isotopes for Imaging and Therapy

M. Harris; Clarity Pharmaceuticals, Sydney, AUSTRALIA.

PS4   **Saturday, October 21, 2017, 09:00 - 12:00, Hall G1**

Pre-Congress Symposium 4 - Tau Imaging in Humans

PS27

Tau Pathology in Tauopathies

G. Kovacs; Institute of Neurology, Medical University Vienna, Vienna, AUSTRIA.

PS28

Preclinical Pharmacokinetic Modelling: A Strategy to Select and Compare Tracers?

S. Krämer; ETH Zurich, Institute of Pharmaceutical Sciences, Zurich, SWITZERLAND.

PS29

Imaging Tau with 18F-THK5317

A. Nordberg; Center for Alzheimer Research, Karolinska Institutet, Stockholm, SWEDEN.

PS32

Imaging Tau with 18F-T807

B. van Berckel; VUMC, Amsterdam, NETHERLANDS.

PS33

Imaging Tau with 11C-PBB3 and its 18F Derivatives

M. Higuchi; National Institutes for Quantum and Radiological Science and Technology National Institute of Radiological Sciences, Chiba, JAPAN.

PS34

Tau as a Therapeutic Target

C. Wischik; School of Medicine, Medical Sciences and Nutrition, University of Aberdeen, Aberdeen, UNITED KINGDOM.

PS5   **Saturday, October 21, 2017, 09:00 - 12:00, Hall G2**

Pre-Congress Symposium 5 - Validation & Risk Assessment

PS36

Economic Impact of Qualification/Validation from Full GMP Perspective

R. Suchi; GE Healthcare Buchler GmbH & Co. KG, Braunschweig, GERMANY.

PS37

Validation of Analytical Methods

N. M. Gillings; Copenhagen University Hospital, Rigshospitalet, PET & Cyclotron Unit, Copenhagen, DENMARK.

PS38

Risk Assessment - How Much Validation is Needed?

V. Ferrari; The Grove Centre, QA department, Amersham, Buckinghamshire, UNITED KINGDOM.

PS41

Design, Qualification and Validation of a Cyclotron Facility: It's Fun! – Practical Example

L. Perk; Radboud University Medical Center, Radboud Translational Medicine, Nijmegen, NETHERLANDS.

PS42

Risk Assessment – Practical Example

P. Colombo; IBA Molecular Italy, San Gerardo dei Tintori Hospital, Monza, ITALY.

PS6   **Saturday, October 21, 2017, 13:00 - 16:00, Hall F2**

Pre-Congress Symposium 6 - Monte Carlo Simulation / Image Reconstruction – Part II

PS44

Short Introduction to the Principles of Monte Carlo Methods

D. Visvikis; CHU MORVAN, Bat 2 bis, U650 INSERM, LaTIM - I35, Brest, FRANCE.

PS45

Monte Carlo Simulation of PET Systems

Pre-dosing with Lilotomab Prior to Antibody-Radionuclide Conjugate Therapy with ^{177}Lu-Lilotomab Satetraxetan Significantly Increases the Ratio of Tumour to Red Marrow Absorbed Dose in non-Hodgkin Lymphoma Patients

J. Blakkisrud[1], A. Løndalen[2], J. Dahle[3], A. C. Martinsen[4,1], H. Holte[5], A. Kolstad[5], C. Stokke[1,6]; [1]Department of Diagnostic Physics, Oslo University Hospital, Oslo, NORWAY, [2]Division of Radiology and Nuclear Medicine, Oslo University Hospital, Oslo, NORWAY, [3]Nordic Nanovector ASA, Oslo, NORWAY, [4]The Department of Physics,

University of Oslo, Oslo, NORWAY, [5]Department of Oncology, Radiumhospitalet, Oslo University Hospital, Oslo, NORWAY, [6]Oslo and Akershus University College of Applied Science, Oslo, NORWAY.

Introduction: ^{177}Lu-lilotomab satetraxetan is a novel anti-CD37 antibody radionuclide conjugate for treatment of non-Hodgkin lymphoma. Four different combinations of pre-dosing and pre-treatment have been investigated in the phase 1 study. All patients were pre-treated with different regimens of rituximab. Two arms included cold lilotomab pre-dosing (arm 1 and 4; 40 mg fixed and 100 mg/m[2] BSA dosage respectively) and two did not (arm 2 and 3). Patients received either 10, 15 or 20 MBq ^{177}Lu-lilotomab satetraxetan per kg body weight. Previously, we have shown that absorbed red marrow (RM) doses were lower in arm 1 vs arm 2, and that haematological toxicity was more severe for patients receiving higher RM doses. The aim of this work was to compare the ratios of tumour to RM absorbed doses between arm 1, 4 and non-pre-dosed patients (arm 2 + 3). **Subjects and Methods:** A total of 16 patients were included for RM dosimetry, of these 14 were included for tumour dosimetry. A total of 35 tumour lesions were included, 1 to 5 from each patient (mode 3). RM and mean tumour absorbed doses per administered activity were determined from multiple SPECT/CT-images for each patient. Two-sided student-t-tests were used for all statistical analyses. **Results:** The mean RM absorbed doses were 0.83, 0.91 and 1.39 mGy/MBq for arm 1, 4 and non-pre-dosing arms 2+3, respectively. There was a significantly higher RM dose for non-pre-dosing compared to arm 1 (p = 0.04), and arm 4 (p = 0.05). Mean tumour absorbed doses were 1.62, 2.78 and 1.37 mGy/MBq for arm 1, 4 and non-pre-dosing respectively. Tumour doses were higher in arm 4 patients compared to patients without pre-dosing (p = 0.04). Tumour doses in arm 1 were not significantly higher compared to non-pre-dosing (p = 0.71). The mean tumour to RM absorbed dose ratios were 2.16, 3.93 and 1.07 for arm 1, 4 and non-pre-dosing respectively. Ratios were significantly higher in both arm 1 and 4 compared to non-pre-dosing (p = 0.05 and p = 0.04). No statistically significant difference between arm 1 and 4 was found for any parameters (p >= 0.12). **Conclusion:** Pre-dosing with lilotomab has a mitigating effect on red marrow absorbed dose for ^{177}Lu-lilotomab satetraxetan patients, and increased pre-dosing amounts was found correlated with a higher tumour dose. While the optimal amount of lilotomab is yet to be investigated, both pre-dosage levels significantly increased the tumour to RM absorbed dose ratio.

OP-013

Bi-213-anti-EGFR-MAb therapy of recurrent bladder cancer - a pilot study

K. Scheidhauer[1], C. Seidl[1], F. Bruchertseifer[2], C. Apostolidis[2], M. Autenrieth[1], F. Kurtz[1], T. Horn[1], M. Schwaiger[1], J. Gschwend[1], C. D'Alessandria[1], C. Pfob[1], R. Senekowitsch-Schmidtke[1], A. Morgenstern[2]; [1]Technische Universität München, München, GERMANY, [2]EC, JRC, Directorate for Nuclear Safety and Security, Karlsruhe, GERMANY.

Purpose/Introduction: Following transurethral resection of non-muscle-invasive bladder cancer (carcinoma in situ) and subsequent chemotherapy and treatment with Bacillus Calmette-Guérin (BCG), up to 40% of patients relapse within 5 years and need complete bladder excision. Therefore, new therapeutic strategies to combat tumor recurrence are needed. Because treatment of mice bearing intravesical human bladder cancer xenografts with Bi-213-anti-EGFR-MAb turned out highly efficient, the aim of this pilot study was to evaluate feasibility, safety and therapeutic efficacy of the α-emitter radioimmunoconjugate in recurrent bladder cancer patients. **Subjects & Methods:** The alpha-emitter Bi-213 was eluted from a Ac-225/Bi-213 generator system and coupled to the anti-EGFR-MAb (cetuximab, Merck, Germany) via the chelating agent CHX-A"-DTPA. 12 patients (10 m, 2 f) suffering from carcinoma in situ bladder cancer that had shown no response to BCG treatment were intravesically applied with 366-821 MBq (9.9 - 22.2 mCi) of Bi-213-anti-EGFR-MAb in 40 ml of PBS. Distribution of Bi-213-anti-EGFR-MAb was monitored by SPECT/CT. Treatment was terminated by emptying of the radioimmunoconjugate from the bladder up to 120 min after injection. Efficacy was evaluated via endoscopy and histology after eight weeks, and then six-monthly. Results: All patients (pts) showed excellent toleration of the treatment without any side effects. SPECT/CT monitoring clearly revealed location of the Bi-213-anti-EGFR-MAb immunoconjugate in the bladder. Treatment resulted in a documented complete eradication of tumor cells in three patients (CR is lasting 2.1 yrs, resp. 3.2 yrs, 1 pt with relapse after six months), PR in one patient and progressive tumor growth in eight patients. **Discussion/Conclusion:** Intravesical instillation of Bi-213-anti-EGFR-MAb is a promising, well tolerated therapeutic option for treatment of in situ bladder cancer after BCG failure and can help to avoid or postpone radical bladder surgery. A follow up study is planned to investigate further improvement of therapeutic efficacy through dose escalation and repeated treatments.

OP-014

Synfrizz : A first in Man study investigating the biodistribution, the safety and optimal recommended dose of a new radiolabeled monoclonal antibody targeting Frizzled homolog 10 (FZD10) in patients with relapsed or refractory non resectable synovial sarcomas

A. Giraudet[1], P. Cassier[1], G. Garin[1], J. Badel[1], S. Baconnier[1], D. Sarrut[2], D. Kryza[3], C. Iwao-Fukukawa[4], Y. Nakamura[5], A. Halty[6], D. Perol[1], J. Blay[1]; [1]Centre Léon Bérard, Lyon, FRANCE, [2]Créatis, Lyon, FRANCE, [3]UCBL1, Lyon, FRANCE, [4]OncoTherapy Science, Kawasaki City, JAPAN, [5]University of Tokyo, Tokyo, JAPAN, [6]Creatis, Lyon, FRANCE.

Introduction: Synovialosarcoma (SS) are rare tumors occurring predominantly in adolescents and young adults. Standard of care for relapsing SS is rarely curative and median survival is close to 12 months. OncoTherapy Science (Japan) has developed a monoclonal antibody (OTSA101) targeting the receptor frizzled-10 (FZD-10) highly expressed by SS but not present in normal tissues. When it was radiolabeled with ^{90}Y, tumor

shrinkage was observed in immunocompromised mice bearing FZD10-positive SS tumors, without significant toxicity. These preclinical data supported the clinical application of ^{90}Y-OTSA101 in a first in man phase I trial. **Subjects and Methods:** This study was conducted as a theranostic trial and included advanced SS patients resistant to standard treatments. In the first part, patients received 275 MBq of ^{111}In-OTSA101 in order to evaluate the in vivo bio-distribution and tumor uptake on repeated whole body and SPECT-CT acquisitions. In the second part, patients with significant tumors radiotracer uptake were randomized between 370 MBq (Arm A) and 1110 MBq (Arm B) of ^{90}Y-OTSA101. Patients' follow-up evaluated the safety and tumors response. 3D dosimetry with Monte Carlo simulations (GATE) was performed to evaluate normal tissues and selected tumor lesions absorbed dose (AD). **Results:** From January 2012 to June 2015, 20 pts (10 females, median age 43 years, [21-67]) with advanced SS were enrolled. Ten patients had sufficient tumor uptake to proceed to part 2 and 8 were randomized (Arm A: 3; Arm B: 5). Two patients were not randomized due to worsening PS. During part 2, the most common Grade ≥ 3 AEs were haematological, and were more common in Arm B. This was explained by 3D dosimetry as the bone marrow AD was closer to the MTD than in any other normal tissues (median, 0.09 cGy/MBq; [0.02–0.18] for a 2 Gy bone marrow MTD). One patient with SD after 12 weeks received a 2nd injection of 90Y-OTSA101, but experienced fatal hemoptysis afterwards. No objective response was observed explained by 3D dosimetry as the maximal tumor AD was 10 Gy (median, 0.25 cGy/MBq [01 to 0.82]). Best response was stable disease in 5/8 patients lasting up to 21 weeks for 1 patient. **Conclusion:** This first in human study shows that radioimmunotherapy targeting FZD10 is feasible and safe in metastatic SS patients. Tumor uptake was heterogeneous but sufficient to select 50% of pts for 90Y-OTSA101 treatment. 3D dosimetry results appeared to be correlated with side effects and tumors responses.

OP-015

Radioimmunotherapy with Panitumumab Modified with Metal Chelating Polymers (MCP) Labeled with ^{111}In and ^{177}Lu - A Novel Theranostic for Pancreatic Cancer

S. Aghevlian[1], D. Hedley[2], M. Winnik[3], R. Reilly[1,4,5]; [1]Department of Pharmaceutical Sciences, University of Toronto, Toronto, ON, CANADA, [2]Princess Margaret Cancer Centre, University Health Network, Toronto, ON, CANADA, [3]Department of Chemistry, University of Toronto, Toronto, ON, CANADA, [4]Toronto General Research Institute and Joint Department of Medical Imaging, University Health Network, Toronto, ON, CANADA, [5]Department of Medical Imaging, University of Toronto, Toronto, ON, CANADA.

Aim: Our aim was to study radioimmunotherapy (RIT) of pancreatic cancer (PnCa) using a novel theranostic agent composed of panitumumab (PmAb; anti-EGFR) conjugated to hydrazino nicotinamide metal chelating polymers (HyNic-MCP) harbouring 13 DOTA chelators for labeling with ^{111}In and ^{177}Lu, and 10 polyethyleneglycol (PEG) chains to minimize liver and spleen uptake. ^{111}In (t$_{1/2}$ = 2.8 d) emits γ-radiation [Eγ=171, 245

keV] enabling SPECT and subcellular range Auger electrons ideal for RIT of micrometastases. ^{177}Lu (t$_{1/2}$=6.7 days) is a β-emitter [Eβ(max)=0.2-0.5 MeV] suitable for treatment of millimeter sized tumours, that emits two γ-photons for SPECT imaging [Eγ=113, 208 keV]. Imaging may aid in selection of patients for RIT and estimating radiation doses to tumors and normal organs. **Methods:** The tumor-growth inhibitory effects of ^{111}In-MCP-PmAb were compared to ^{111}In-DOTA-PmAb in NOD/SCID mice engrafted s.c. with EGFR-positive PANC-1 human PnCa xenografts. For 70 days, every 3 weeks mice were injected i.v. with 10 μg (11 MBq) of ^{111}In-MCP-PmAb, ^{111}In-DOTA-PmAb, unlabeled PmAb or saline. Since NOD/SCID mice are radiation sensitive, RIT with ^{177}Lu-MCP-PmAb or ^{177}Lu-DOTA-PmAb was performed in NOD-Rag1(null)IL2rγ(null) (NRG) mice. NRG mice with PANC-1 tumours were injected i.v. with 10 μg (7 MBq) of ^{177}Lu-MCP-PmAb or ^{177}Lu-DOTA-PmAb every 6 weeks for 75 days. Tumor size was monitored and changes in body weight assessed every 2-3 days. A tumor growth index (TGI) was calculated by dividing the tumour volume at each time point by the initial volume. A body weight index (BWI) was similarly calculated. **Results:** The mean TGI (P-values compared to untreated mice) at 33 days in NOD/SCID mice treated with ^{111}In-MCP-PmAb, ^{111}In-DOTA-PmAb, PmAb and saline were 2.3±0.2 (p<0.001), 2.9±0.3 (p<0.001), 5.7±1.2 (p<0.001) and 18.6±3.5, respectively. The mean TGI at this time point in NRG mice treated with ^{177}Lu-MCP-PmAb, ^{177}Lu-DOTA-PmAb, PmAb and saline were 2.7±0.7 (p<0.01), 1.8±0.7 (p<0.001), 6.0±2.7 (p>0.05) and 5.8±0.9. No body weight loss was observed in any treatment groups. **Conclusions:** Both ^{111}In- or ^{177}Lu-MCP-PmAb or DOTA-PmAb decreased tumor growth compared to untreated mice. However, in a separate study, we found that MCP conjugation permits more robust and higher specific activity radiolabeling than DOTA-conjugated PmAb. Unlabeled PmAb was less effective than RIT at inhibiting tumor growth. The effectiveness of unlabeled PmAb for inhibiting tumor growth compared to untreated controls varied with the strain of mice used for tumor implantation. **Research Support:** Supported by the Canadian Cancer Society, Cancer Research Society, Centre for Pharmaceutical Oncology,and STARS21 strategic training program in radiation research.

OP-016

Radium-223-Dichloride in Castration-Resistant Metastatic Prostate Cancer: Therapy Assessment with 11C-choline PET/CT and Bone Scan

P. Ghedini[1], T. Graziani[1], E. Lodi Rizzini[1], G. Lima[1], I. Bossert[2], F. Ceci[1], G. Montini[1], C. Pettinato[3], F. Monari[4], V. Dionisi[5], A. Morganti[4], P. Castellucci[1], S. Fanti[1]; [1]Nuclear Medicine S. Orsola-Malpighi Hospital - University of Bologna, Bologna, ITALY, [2]Nuclear Medicine & Physics Unit, Fondazione Salvatore Maugeri, Pavia, ITALY, [3]Fisica Sanitaria - S. Orsola-Malpighi Hospital - University of Bologna, Bologna, ITALY, [4]U.O. Radioterapia - S. Orsola-Malpighi Hospital - University of Bologna, Bologna, ITALY, [5]U.O. Radioterapia - S. Orsola-Malpighi Hospital - University of Bologna, Bologna, ITALY, Bologna, ITALY.

Aim: our purpose was to evaluate Radium-223 therapy with [11C]Choline PET/CT and Bone Scan in patients with symptom-

atic bone metastases in castration-resistant prostate cancer (mCRPC). **Material and Methods:** we retrospectively enrolled 32 patients (age mean/range=72.4/58-88 years-old) by using these inclusion criteria: 1) mCRPC patients with symptomatic bone metastases 2) 6 subsequent cycle of Radium-223-Dichloride (55 kBq/kg); c) [11C]choline-PET/CT and Bone scan performed at baseline (BS1; PET1) and two months after the last cycle of radium223 (BS2; PET2). PSA, Alkaline phosphatase (ALP), and Hemoglobin (Hb) values were measured before (mean value=2.7 months) and after the end of therapy (mean value=2.8 months). BS2 and PET2 were reported by two nuclear medicine physicians as complete (CR), partial response (PR) or stable disease (SD). The appearance of a new lesion at BS2 or PET2 was reported as progression disease (PD). Follow-up (Clinical and radiological) was from 6 - to 18 months (mean 14.6 months). **Results:** the 56.3% (18/32) of patients were reported PR at PET2; 28.1% (9/32) showed a PD of bone metastasis; 9.4% (3/32) were in SD at PET2; 6.3% (2/32) were in CR at PET2. Considering the 18 patients with PR, CR or SD the 83% (15/18) showed increasing PSA-trend while considering the 9 patients with PD at PET2, the 77.7% (7/9) showed increasing PSA-trend. 100% of responders patients at imaging showed a significant decrease of ALP (mean reduction of 41.6%). 75% (22/32) of patients showed PR at BS2, 6.3% (2/32) CR, 25% (8/32) of patients showed PD at BS2: 1 PET2 in PD resulted CR at BS2; 3 PET2 in SD were PR at BS2; 1 PET2 in CR was PR at BS2. BS2 discordant results were confirmed with clinical and radiological follow up. Responders patients at imaging (PR/CR at BS2) showed a significantly better Overall Survival (OS) compared with non-responders (19.7 months vs 15.1). 46% of patients showed progression disease in visceral or lymph nodes at PET2. **Conclusion:** our preliminary results showed that Bone Scan is a more useful tool than [11C] Choline PET/CT in Radium 223 therapy assessment. However, Choline PET/CT is important to identify visceral or lymph nodes disease progression. Responders patients at Bone Scan seem to have better OS.

OP-017

Quantification of skeletal tumor burden on bone scintigraphy for prediction of overall survival in Radium-223 therapy

M. Ø. Fosbøl, P. M. Petersen, A. Kjaer, J. Mortensen; Rigshospitalet, Copenhagen, DENMARK.

Background: The role of bone scintigraphy in prediction and response assessment in Radium-223-dichloride (Ra-223) approved for metastatic castration-resistant prostate cancer (mCRPC) is not fully elucidated. The aim of this study was to investigate the predictive value of visual assessment of bone scintigraphy and automated quantification of skeletal tumor burden (Bone Scan Index) in mCRPC patients receiving Ra-223. **Methods:** National study of the Danish mCRPC patients who received ≥ 1 cycle of Ra-223 from March 2014 to October 2015 and who had a baseline bone scintigraphy available. Baseline bone scintigraphies were reviewed and graded according to extent of disease (EOD). Scintigraphic response to therapy after

three cycles and at end of therapy (EOT) was evaluated according to Prostate Cancer Working Group 2 (PCWG-2). All scintigraphies were analysed with the software EXINI Bone[BSI] Version 2 (EXINI Diagnostics, Lund, Sweden) to obtain Bone Scan Index (BSI). Primary outcome was overall survival (OS) from first cycle of Ra-223 to death of any cause. Parameters included in Cox regression analysis were: baseline BSI, visual grading of EOD, serum alkaline phosphatase (ALP), serum lactate dehydrogenase (LDH), serum PSA, opioid use and presence of lymph node metastases. **Results:** A total of 88 mCRPC patients were included. Baseline EOD showed 75% of patients (n=66) had > 20 metastases or superscan. Median baseline BSI was 5.0. Significant predictors of OS were baseline BSI (HR 1.042 per unit increase, p=0.035) and LDH (HR 1.02 per unit increase (U/l), p<0.001). Median OS for patients with BSI > 5 was 8.2 months vs. 15.0 months for BSI ≤ 5 (HR 2.65, p=0.001). BSI was stable or decreased during therapy in 44% (n=23) of patients who completed three cycles and in 59% (n=19) of patients after EOT. No association between changes in BSI during therapy and OS was found. Bone scintigraphy response according to PCWG from baseline to EOT showed stable disease in 38% (n=12), progression in 63% (n=20) and response was significantly associated with OS. Median OS for patients who progressed during therapy was 11.9 months (95% CI: 8.0-15.7), while median OS was not reached for patients with stable disease (HR 5.82, 95% CI: 1.31-25.9). **Conclusion:** Automated BSI is a promising biomarker for prediction of OS in mCRPC patients with advanced disease receiving Ra-223. Bone scintigraphy response according to PCWG-2 during Ra-223 therapy is associated with OS. Further studies are needed to evaluate the potential for BSI in response assessment.

OP-018

Radium-223 in Combination with Paclitaxel in Cancer Patients wiith Bone Metastases: Safety Results from an Open-Label, Multicenter Phase 1b Study

J. S. Lopez[1], R. Perets[2], S. Danson[3], H. Joensuu[4], A. Peer[2], S. J. Harris[1], F. Souza[5], B. Ploeger[6], K. M. C. Pereira[7], R. Geva[8]; [1]The Royal Marsden Hospital and The Institute of Cancer Research, Sutton, UNITED KINGDOM, [2]Rambam Health Care Campus, Haifa, ISRAEL, [3]Sheffield Experimental Cancer Medicine Centre, Weston Park Hospital, Sheffield, UNITED KINGDOM, [4]Helsinki University Hospital, Helsinki, FINLAND, [5]Bayer HealthCare Pharmaceuticals, Whippany, NJ, UNITED STATES OF AMERICA, [6]Bayer Pharma AG, Berlin, GERMANY, [7]Bayer Pharma AG, São Paulo, BRAZIL, [8]Tel Aviv Sourasky Medical Center, Tel Aviv, ISRAEL.

Aim: Concomitant radium-223 and chemotherapy is a potential option for cancer patients with bone metastases. Both therapies impact hematologic parameters, and myelosuppression risk during coadministration is unknown. This phase 1b study in cancer patients with bone metastases evaluated radium-223+paclitaxel safety and mode of interaction regarding myelosuppression. **Materials and Methods:** Eligible patients had a confirmed malignant solid tumor with ≥2 bone metastases and were candidates for paclitaxel. Treatment included 7 paclitaxel cycles (90

mg/m²/wk IV per local standard of care; 3 wk on/1wk off) + 6 radium223 cycles (55 kBq/kg IV; 1 injection every 4 wk, starting at paclitaxel cycle 2). The primary end point was percentage of patients with neutropenia and thrombocytopenia during treatment with radium223+paclitaxel (cycles 2, 3) versus paclitaxel alone (cycle 1). A previously developed dose-exposure-response model describing the time course of radium-223+paclitaxel-induced suppression of absolute neutrophil counts was used to evaluate radium-223+paclitaxel mode of interaction (additive or synergistic). **Results:** Of 22 enrolled patients, 15 were treated; 13 completed cycles 1-3 and were included in the pharmacodynamics analysis; 7 completed all 6 radium-223 cycles. Tumors in treated patients were breast (7 patients), prostate (4 patients), bladder (1 patient), non-small cell lung (1 patient), myxofibrosarcoma (1 patient), and neuroendocrine (1 patient). 7 patients received ≥3 prior chemotherapy treatments. Grade 3/4 treatment-emergent adverse events (TEAEs) occurred in 9 patients, grade 5 TEAEs in 2 patients (both associated with disease progression and unrelated to study treatment), and serious TEAEs in 6 patients. No patients discontinued treatment due to toxicity from the treatment combination. 13 patients had paclitaxel dose modifications (interruptions in 11 and reductions in 5); 5 patients had radium-223 dose modifications (all interruptions). Grade 3/4 TEAEs occurring in >10% of patients were neutropenia (40%), white blood cell count decreased (13%), and leukopenia (13%). In 13 patients who completed cycle 3, grade 3 neutropenia rates in cycles 2 and 3 were 31% and 8%, respectively, versus 23% in cycle 1; there were no cases of grade 4 neutropenia or grade 3/4 thrombocytopenia. The myelosuppression model showed an additive effect of radium-223 to paclitaxel-induced neutropenia, with an additional 10% average decrease in absolute neutrophil count versus paclitaxel alone. **Conclusion:** Radium-223 was well tolerated when combined with paclitaxel, with an additional 10% average decrease in neutrophil levels versus paclitaxel monotherapy, but no other significant additive toxicity. This combination should be explored further in patients with bone metastases.

OP-019

Analysis of Clinical parameters for the outcame prediction of mCRPC patients treated with [223]Ra-dichloride

V. Frantellizzi, G. A. Follacchio, S. Sollaku, J. Lazri, A. Farcomeni, M. Pacilio, M. Liberatore, F. Monteleone, G. De Vincentis; *Sapienza University of Rome, Rome, ITALY.*

Aim: Treatment with [223]Ra-dichloride in mCRPC patients is in use for several years with an increasing clinical experience. It has tried to find some parameters that may predict the prognosis of these patients. PSA and tALP have been extensively studied. Purpose of this study is to evaluate whether the Hemoglobin value associated with numbers of previous chemotherapeutic treatment can be assumed as a predictive tool for Overall Survival (OS). **Materials and Methods:** [223]Ra-dichloride (55 KBq/Kg IVq4w) was administered to 92 consecutive mCRPC symptomatic patients in our Nuclear Medicine Unit in 17 months. Baseline Hemoglobin value and number of systemic treatments prior [223]Ra were evaluated. Multivariate analysis were performed and a ROC curve was built. **Results:** 390 [223]Ra cycles were administered to 92 patients (mean age 73 years). Among 92 patients, 40 (43%) completed the 6 scheduled administrations, 27 patients (29%) discontinued [223]Ra treatment while 25 (27%) were still receiving [223]Ra therapy at the time of analysis. 44 patients were deceased while 22 were in follow-up. 46 (50%) patients had baseline Hemoglobin value higher than 12g/dl. 20 patients (22%) did not receive any treatment before [223]Ra administration, 30 patients (32%) received 1 treatment, 24 patients (26%) received 2 treatments, finally 18 patients (20%) received 3 or more systemic treatments prior [223]Ra. From the start of [223]Ra therapy the median follow-up time was 6 months (1-31). Patients with a baseline Hemoglobin value higher than 12g/dl and lesser of 2 previous chemotherapeutic treatment had a median OS of 10 months (95%CI 7-16 months). Baseline patients' Hemoglobin and number of treatment at multivariable analysis were significantly correlated with OS (HR=0.71, 95%CI 0.58-0.86, *p*<0.001). **Conclusions:** [223]Ra therapy is related to survival and the choice of parameters that improve the prognosis is a continuous challenge. The high Hemoglobin value before the onset of [223]Ra therapy and lower number of previous systemic therapies show a significantly increased survival due to the preserved bone marrow reserve that is crucial in these patients. We recommend, when it is possible, to start early [223]Ra therapy.

M2M: α-Therapy

OP-020

Preclinical evaluation of astatinated nanobodies for targeted alpha therapy

Y. D. Dekempeneer[1,2], M. D'Huyvetter[1], E. Aneheim[3], C. Xavier[1], T. Lahoutte[1,4], T. Bäck[3], H. Jensen[5], V. Caveliers[1,4], S. Lindegren[3]; [1]Vrije Universiteit Brussel, Jette/ Brussel, BELGIUM, [2]Belgian Nuclear Research Center (SCK•CEN), Mol, BELGIUM, [3]Targeted Alpha Therapy group, University of Gothenburg, Gothenburg, SWEDEN, [4]Nuclear Medicine Department (UZBrussel), Jette/ Brussel, BELGIUM, [5]Cyclotron and PET Unit, Copenhagen, DENMARK.

The use of nanobodies (Nbs) as vehicles in targeted alpha therapy (TAT) has gained traction due to their excellent *in vivo* properties, high affinity and specificity and fast clearance kinetics. This study investigates a novel targeted therapy which combines the α-particle emitter Astatine-211 ([211]At) and the HER2-targeting 2Rs15d-Nb to selectively kill HER2[+] metastases. To achieve astatinated 2Rs15d-Nbs, two different radiochemical methodologies were validated using 3 prosthetic groups. In the "random labeling method", the primary amines of lysines on the Nb are used as conjugation sites. The "site-specific labeling approach" aims at obtaining a homogeneous tracer population with a fixed conjugation. Here the prosthetic group is conjugated to the carboxyl-terminal cysteine of 2Rs15d-His6-Linker-Cys. The different conjugates were evaluated for their

binding specificity, immunoreactivity and degree of internalisation in HER2+ SKOV-3 cells. Moreover, *in vivo* evaluation in HER2+ SKOV-3 tumor xenografts gave us more insight in the biodistribution of the 3 different 211At-Nbs radioimmunoconjugates. 2Rs15d-Nb was randomly labeled with 211At via the prosthetic groups N-succinimidyl-3-(trimethylstannyl)benzoate (**m-eATE**) and N-succinimidyl3-[211At]astato-4-guanidino-methylbenzoate (**SGMAB**), while 2Rs15d-His6-Linker-Cys was site-specifically labeled using N-[2-(maleimido)ethyl]-3-(trimethylstannyl)benzamide (**MSB**). The immunoreactive fraction (IRF) was evaluated on HER2+ cells using the Lindmo assay. *In vivo* biodistribution of the 3 different 211At-Nbs was evaluated in HER2+-SKOV-3 tumor xenografts. Furthermore, *ex vivo* α-camera imaging was done on tumor, kidneys, stomach, lungs, spleen. Radioastatination of 2Rs15d-Nb using m-eATE resulted in a radiochemical yield (RCY) of 75,4% and a RP of 99,09%. The use of SGMAB resulted in a RCY of 31,02% and a RP of 98,44%. Finally, the site-specific labeling with MSB resulted in a RCY of 73% and a RP of 96,34%. The IRF of astatinated me-ATE-, SGMAB- and MSB-Nb was 51,3%, 65% and 78%, respectively. Furthermore, binding to HER2 could be blocked (p<0.0001) for the three different astatinated Nbs, confirming its specificity of binding. The tumor uptake of 211At-SGMAB-Nb was 8,86;5,18; 5,35; 0,94 % ID/g at 1, 3, 6 and 24 h, respectively. Except for the kidneys, rapid clearance of 211At-SGMAB-Nb from normal tissues was observed. Although higher activity levels were measured in stomach, lungs and spleen of m-eATE and MSB coupled Nbs. Based on this preclinical data, 211At-SGMAB-Nb is the preferred radioimmunoconjugate for targeting HER2-expressing malignancies, due to its superior labeling purity, IRF, binding specificity, internalization rate and biodistribution. Overall, the results are highly encouraging and suggest that 211At-labeled anti-HER2-Nbs requires further investigation and optimization.

OP-021

Locoregional alpha-RIT, a novel therapeutic option, against peritoneal metastasis of gastric cancer

H. K. Li[1,2,3], Y. Morokoshi[3], S. Hasegawa[3]; [1]Graduate School of Medical and Pharmaceutical Sciences, Chiba University, Chiba, JAPAN, [2]Research Fellow of Japan Society for the Promotion of Science, Tokyo, JAPAN, [3]National Institute of Radiological Sciences, QST, Japan, Chiba, JAPAN.

Objective: Gastric cancer is one of the main causes of cancer related death. It is curable at early stage, but it often being found at late stage with metastasis because of the asymptomatic. Patients with peritoneal metastasis of gastric cancer (PMGC) have extremely poor prognosis because no effective therapeutics has been established. About 20% of GC is reported as HER2-overexpressed (HER2+), and a humanized anti-HER2 monoclonal antibody, trastuzumab, has been clinically used for the treatment of HER2+ PMGC. Locoregional radioimmunotherapy (RIT) has huge advantage in targeting metastatic cancer existing inside of body cavities, such as PM, for delivering radioisotopes directly to the tumor. Alpha-emitter is getting higher attention for the application to RIT because its physical characteristics, high liner

energy transfer and short range, meet the conception of ideal RIT, providing higher damages to targeted tumor and limit damage to surround normal tissues. Astatine 211 (211At) is one of the attractive alpha-emitter for clinical use. The aim of this study is to establish an efficient alpha-RIT against HER2+ PMGC by evaluating the advantage and therapeutic efficacy of locoregional alpha-RIT with 211At-trastuzumab using preclinical mouse model. **Material and Methods:** 211At was produced via 209Bi(α,2n)211At reaction using cyclotron in NIRS and labeled to trastuzumab. PMGC mouse model was established by injecting luciferase labeled N87, HER2+ human GC cell line, into the abdominal cavity of SCID mice a week before the treatment. The biodistribution of 211At-trastuzumab in PMGC model mice with both intraperitoneal (i.p.) and intravenous (i.v.) injection were monitored up to 24 h post injection. Locoregional alpha-RIT was demonstrated by injecting 211At-trastuzumab (1 MBq) i.p. to PMGC model mice and monitored the tumor by in vivo bioluminescence images. PBS, intact trastuzumab and free 211At (1MBq) were also injected to mice as individual controls. The number of white blood cells (WBC) and bodyweight were monitored to check the side effects. **Results:** The biodistribution results referred faster and higher tumor accumulation of 211At-trastuzumab by i.p. compare to i.v. injection. The activity of 211At in blood was able to be reduced by i.p. injection. Locoregional alpha-RIT with 211At-trastuzumab effectively cured PMGC in vivo and significantly prolonged the survival of preclinical model mice compare to other controls. No significant leukopenia and bodyweight loss were observed. **Conclusions:** Our preclinical study suggested that locoregional alpha-RIT with 211At-trastuzumab could be a novel therapeutic option for HER2+ PMGC.

OP-022

Re-localization of 212Pb from 224Ra sources due to thoron (220Rn) diffusion

E. Napoli[1,2,3], S. Westrøm[1,2,3], T. B. Bønsdorff[3], Ø. S. Bruland[1,2,3], R. H. Larsen[4]; [1]University of Oslo, Oslo, NORWAY, [2]The Norwegian Radium Hospital, Oslo, NORWAY, [3]Oncoinvent AS, Oslo, NORWAY, [4]Sciencons AS, Oslo, NORWAY.

Aim: Alpha-particle-emitting radium nuclides have been the subject of considerable biomedical research due to their highly localized effect. Radium-224, with a convenient half-life of 3.6 days, has promising properties for use against micro-metastatic disease. The aim of this work was to investigate the radiation safety aspects with a focus on thoron (220Rn) diffusion from its parent nuclide 224Ra. Thoron diffusion was studied for 224Ra either as free cation in solution or bound to biocompatible calcium carbonate (CaCO3) microparticles. **Materials and Methods:** Radium-224 was extracted from 228Th immobilized on Actinide Resin in 1 M hydrochloric acid (HCl). The acid was evaporated and the residue reconstituted in 0.1 M HCl and subsequently neutralized with ammonium acetate. The CaCO3 microparticles were prepared by precipitation of the combination of sodium carbonate and calcium chloride solutions. Thereafter, the microparticles were radiolabeled by mixing with 224Ra solution at neutral pH. Re-localization of 212Pb, due to thoron escape from solu-

tions of free ^{224}Ra and ^{224}Ra-CaCO$_3$ microparticle suspensions, was studied in various experimental setups. The potential leakage of thoron was examined from frequently used containers such as: 1.5/5 ml Eppendorf tubes, 6 ml Chromacol head-space injection vials capped and crimped with a stopper and different size of syringes. In addition, the influence of liquid volume on thoron diffusion into air was studied from open vials. Due to its short physical half-life of 56 s, thoron diffusion into the air was evaluated by measuring its decay product ^{212}Pb, which has a longer half-life of 10.64 h. Gamma-counting was performed with the Hidex Automatic Gamma Counter (Turku, Finland). **Results:** The results indicate that free cationic ^{224}Ra solutions and ^{224}Ra-CaCO$_3$ microparticle suspensions can be used in a safe manner, without significant leakage of thoron, when contained in vials or syringes. The data shows that at very low volumes *i.e.* 10-100 μl, there is significant diffusion of thoron from free cationic ^{224}Ra solutions into air from open vials. Less diffusion from open vials was observed with ^{224}Ra-CaCO$_3$ suspensions. Diffusion from 10 μl volumes was between 70% and 95% less for ^{224}Ra-CaCO$_3$ in comparison with free cationic ^{224}Ra solutions. **Conclusion:** When considering the low expected activity level needed for a therapeutic dosing, the current work indicates that, with certain precautions, ^{224}Ra based biomedical products can be used in a safe manner for the hospital staff and patients.

OP-024

Novel Intracavitary α-Therapeutic Based on Calcium Carbonate Microparticles As Carriers for ^{224}Ra: Biodistribution and Toxicity in Mice

S. Westrøm[1,2,3], *T. B. Bønsdorff*[3], *M. M. Malenge*[3], *Ø. S. Bruland*[1,2,3], *R. H. Larsen*[4]; [1]*University of Oslo, Oslo, NORWAY,* [2]*The Norwegian Radium Hospital, Oslo University Hospital, Oslo, NORWAY,* [3]*Oncoinvent AS, Oslo, NORWAY,* [4]*Sciencons AS, Oslo, NORWAY.*

Aim: Peritoneal carcinomatosis occurs when cancer cells from a primary tumor in an adjacent organ migrate into the peritoneal cavity and cause micrometastases. Intraperitoneal radiation therapy with β-emitting ^{32}P-colloid was previously used in treatment of ovarian cancer. It was shown to be as effective as adjuvant cisplatin, but resulted in higher incidence of late bowel complications, most likely caused by the several millimeters range of ^{32}P-electrons. Our aim was to design an intracavitary treatment for peritoneal carcinomatosis with highly localized effect to minimize risk of irradiation of surrounding normal tissues. We have developed a novel therapeutic based on CaCO$_3$ microparticles as carriers for the α-emitter ^{224}Ra, a nuclide which emits four α-particles during its decay and has considerably shorter range than ^{32}P. Here, the preparation of the product is presented along with evaluation of tissue distribution and toxicity in mice. **Materials and Methods:** CaCO$_3$ microparticles with median diameters from 2-20 μm were prepared by spontaneous precipitation and radiolabeled by co-precipitation of ^{224}Ra on the particle surface. The labeling yield was determined and retention of ^{224}Ra on the microparticles was investigated *in vitro*. Biodistribution after intraperitoneal administration of the radiolabeled microparticles was studied in immunodeficient

athymic nude mice and compared with that of free ^{224}Ra. Toxicity of the ^{224}Ra-labeled CaCO$_3$ microparticles was evaluated in immunocompetent BALB/c mice. **Results:** Radiolabeling of the CaCO$_3$ microparticles was successful and resulted in high yield. Experiments also showed that ^{224}Ra was well retained on the microparticles for several days *in vitro*. Because of the bone-seeking capacity of ^{224}Ra, the stability of the radiolabeled particles *in vivo* could be determined from the uptake of ^{224}Ra in mice femurs. A fundamental shift in tissue radiation exposure was observed when free ^{224}Ra was compared with ^{224}Ra-labeled CaCO$_3$ microparticles. The femur uptake of ^{224}Ra was significantly reduced and radioactivity on intraperitoneal tissues and surfaces was substantially increased after administration of ^{224}Ra-labeled CaCO$_3$ microparticles. In immunocompetent mice, doses up to 1000 kBq/kg of ^{224}Ra-labeled microparticles were well-tolerated and no clinical signs of toxicity were observed. **Conclusion:** Efficient ^{224}Ra-labeling of the CaCO$_3$ microparticles was achieved with high retention of the radionuclide by the particles *in vitro*. The *in vivo* studies show that ^{224}Ra-labeled CaCO$_3$ microparticles could be safely administered in mice at therapeutically relevant doses and with a high degree of intraperitoneal retention. In conclusion, the novel α-emitting microparticles have properties that make them a promising new modality for intracavitary cancer therapy.

OP-025

A Novel Multi-Component Reaction for ^{211}At-Astatination: Providing new Tools for (pre)Targeted Alpha Therapy

C. Denk[1], *E. H. K. Aneheim*[2], *S. Lindegren*[2], *M. Herth*[3,4], *M. Wilkovitsch*[1], *H. Mikula*[1]; [1]*Vienna University of Technology, Vienna, AUSTRIA,* [2]*The Sahlgrenska Academy, University of Gothenburg, Gothenburg, SWEDEN,* [3]*Ringhospitalet, Copenhagen, DENMARK,* [4]*University of Copenhagen, Copenhagen, DENMARK.*

Purpose & Introduction: The α-emitter ^{211}At is a highly promising radionuclide for targeted alpha therapy (TAT). ^{211}At is the only α-emitter used in therapy that allows for covalent labeling, thus preventing the use of chelators. Although astatine is the rarest naturally occurring element, ^{211}At can be produced in medium energy cyclotrons. In general, astatinations are carried out utilizing stannyl-precursors and oxidative conditions. Due to the low abundance of this element, the chemistry of astatine is rather unexplored. The availability of other straight forward radio-astatination procedures would extend the variety of accessible ^{211}At-TAT agents, leading to more options in the treatment of malignant disease. **Methods & Results:** Within this contribution a novel methodology for introduction of ^{211}At into small molecules is presented. In this multi-component labeling reaction, an azide-moiety (**A**), an alkyne-moiety (**B**), and ^{211}At are combined using base and metal catalysis. The product formed consists of a 1,2,3-triazole (**T**) bearing both structural motifs (**A** and **B**) with the astatine located at the triazole system (**A**-**T**(^{211}At)-**B**). The reaction, which is unaffected by high starting activities, was optimized towards reaction time and radiochemical yield (RCY), finally providing >70% RCY within 10 min. The reaction is highly tolerant considering the structural motifs **A**

and **B**, as shown in a related study applying [125]I.[1] This allows high structural variation, enabling straight-forward tuning of pharmacokinetic properties. We chose to use biotin-azide as **A** and tetrazine-alkyne as **B**, giving rise to a [211]At-agent that is suitable for biotin/streptavidin or tetrazine/*trans*-cyclooctene (TCO) based labeling and pre-targeting studies. The structure of the product was verified by binding experiments to TCO and streptavidin modified beads. Stability of the astatine-triazole bond was investigated by incubation of formed [211]At-Beads in plasma for 300min, showing 88% intact substance. Stability was further increased to 99% by click-assembly of a PEG-corona to the bead, using the tetrazine moiety of this multifunctional agent. **Discussion & Conclusion:** To the best of our knowledge we have developed a new, high yielding, fast and versatile labeling system for astatine-211. Applying this chemistry, we prepared the first [211]At-labeled 1,2,4,5-tetrazine that furthermore bears a biotin motif. This agent is capable of binding to TCO and/or streptavidin in a highly efficient manner, providing a tool for pre-targeted alpha radiotherapy (pTAT) and macromolecule labeling. We are convinced that this new astatination-strategy is a step forward towards broader application of TAT by expanding the variety of [211]At based therapeutic agents. [1]Yan et.al *JACS*,2013

OP-026

Bismuth-213 labeled nanobodies as a new treatment approach in Targeted Alpha Therapy

Y. Dekempeneer, Jr.[1,2], *D. Maertens*[2], *M. Gysemans*[2], *T. Lahoutte*[1,3], *M. D'Huyvetter*[1], *T. Cardinaels*[2,4], *V. Caveliers*[1,3]; [1]*Vrije Universiteit Brussel, Jette/ Brussel, BELGIUM,* [2]*Belgian Nuclear Research Center (SCK•CEN), Mol, BELGIUM,* [3]*Department of Nuclear Medicine (UZBrussel), Jette/ Brussel, BELGIUM,* [4]*Department of Chemistry (KU Leuven), Leuven, BELGIUM.*

The use of nanobodies (Nbs) as vehicles in targeted alpha therapy (TAT) has gained traction due to their excellent in vivo properties, high affinity and specificity, fast diffusion and clearance kinetics. Moreover, Nbs show good tumor penetration due to their small size. The main strength of TAT is the potential to deliver a high level of ionizing radiation in a localized manner because of the short range of alpha particles in tissue. In combination with a tumor-seeking vehicle, TAT could specifically eliminate isolated cancer cells, while causing little damage to healthy cells. The aim of this study is to develop a novel molecular targeted therapy that combines the α-particle emitting radioisotope Bismuth-213 ([213]Bi) and the HER2-targeting 2Rs15d-Nb to selectively destroy HER2-positive metastases. From an onsite [229]Th source, the purified [225]Ac is loaded on a pre-packed column containing AG MP-50 cation exchange resin. In dilute acid, both [225]Ac and [213]Bi are efficiently adsorbed to this cation exchange resin due to their stable 3+ oxidation state. [213]Bi is selectively eluted from the cation exchange resin as anionic BiI_4^- / BiI_5^{2-} species. Chemical separation experiments were performed on non-radioactive solutions (were La was used as simulant for Ac) to develop a reliable Ac/Bi separation methodology which will then be applied on radioactive [225]Ac. Different bed volumes

and eluents concentrations were evaluated. Inductively-coupled plasma mass spectrometry (ICP-MS) was used to evaluate the performance of the separation methodology. The final goal is to produce high purity [213]Bi and minimize [225]Ac breakthrough. In a next step, [213]Bi-labeled HER2-targeting 2Rs15d-Nbs will be developed. Therefore, classical diethylenetriaminepentaacetic acid (DTPA) and 1,4,7,10-tetraazacyclododecane-N,N',N'',N'''-tetra-acetic acid (DOTA) derivatives will be used as bifunctional chelator, conjugated to tumor-targeting 2Rs15d-Nbs on one hand and complexing [213]Bi on the other hand. The different conjugates will be evaluated for their stability, binding specificity and immunoreactivity in HER2[pos] SKOV-3 cells. Due to the 46 min half-life of [213]Bi, the [213]Bi labeling reaction and quality control of [213]Bi preparations must be performed in a very short time frame to avoid significant decay losses.

DNA damage in blood leukocytes after internal in-vitro irradiation of blood with the α-emitter ^{223}Ra

S. Schumann[1], U. Eberlein[1], R. Muhtadi[2], M. Lassmann[1], H. Scherthan[2]; [1]University of Würzburg, Würzburg, GERMANY, [2]Bundeswehr Institute of Radiobiology affiliated to the University of Ulm, München, GERMANY.

Introduction: ^{223}Ra-dichloride is the first α-emitter that has been licensed for the treatment of metastatic castration-resistant prostate cancer. In this study we investigate radiation-induced DNA double strand break (DSB) formation by internal irradiation of blood leukocytes with ^{223}Ra using co-localizing foci of γ-H2AX and 53BP1 DNA damage biomarkers. The aim was to quantify the induction of DSBs and to correlate the results to the absorbed dose to the blood, thus generating an in-vitro calibration curve for ^{223}Ra. **Methods:** Blood samples from six healthy volunteers were split into 3.5 ml aliquots to which 1 ml of a ^{223}Ra solution was mixed followed by incubation at 37℃ on a roller-mixer for 1h. Additionally, corresponding baseline samples without radioactivity were prepared. The ^{223}Ra activity in each sample was chosen to result in absorbed doses to the blood up to 150 mGy and determined individually with a calibrated germanium detector. After leukocyte separation, fixation and two-color immunofluorescent staining, the number of the radiation-induced co-localizing γ-H2AX and 53BP1 foci were detected manually using a fluorescence microscope equipped with a red/green double band pass filter. The average absorbed dose rates to the blood per nuclear disintegration in 1 ml of blood were calculated for all nuclides of the decay chain under the assumption that the energy off all non-penetrating particles is deposited locally. **Results:** In contrast to β- and γ-emitters, α-particles do not generate distinct foci but tracks that consist of multiple foci representing complex DNA damage. The number of α-tracks in 100 cells was evaluated for 36 blood samples with absorbed doses ranging from 0 to 142 mGy. A linear regression showed a good correlation (r^2=0.94) between the number of α-tracks per 100 cells and the absorbed dose to the blood. The linearity is in agreement with our previously established calibration curves for distinct foci

generated by β-emitters. The number of foci per cell for small distinct foci assumed to be induced by β-particles was similar to the baseline values, which is in agreement with the low absorbed β-doses (~3.7% of the total absorbed dose). **Conclusion:** A linear relationship between the number of α-induced DNA damage tracks and the absorbed dose to the blood could be established. Since the individual foci in α-tracks cannot be resolved by conventional microscopy techniques, a direct comparison to DNA damage foci values obtained by γ- and β-emitter exposure is currently not possible.

OP-054

Involvement of cell cycle checkpoints in the therapeutic efficacy of ^{177}Lu-lilotomab in non-Hodgkin B-cell lymphoma

A. Pichard[1], A. Courteau[2], S. Marcatili[2], G. Cartron[3], I. Isabelle Navarro-Teulon[1], A. Repetto-Llamazares[4], H. Heyerdahl[4], M. Bardiès[2], J. Dahle[4], J. Pouget[1]; [1]IRCM/INSERMU1194, Montpellier, FRANCE, [2]Centre de Recherche en Cancérologie de Toulouse, Toulouse, FRANCE, [3]Centre Hospitalier Universitaire de Montpellier, Montpellier, FRANCE, [4]Nordic Nanovector ASA, Oslo, NORWAY.

Aims: To elucidate the mechanisms of action of radioimmunotherapy with ^{177}Lu-labeled lilotomab (Betalutin®) directed against the CD37 receptor on non-Hodgkin lymphoma (NHL) B-cells, we have developed a radiobiological approach that discriminates between the cytotoxic effects of unlabelled antibodies and of radiation. Comparison was done with ^{177}Lu-rituximab. **Materials and Methods:** *In vitro*, Ramos (Burkitt), DOHH2 (follicular) and Rec-1 (mantle) lymphoma cell lines were exposed for 18 hours to increasing activities (0—6 MBq/mL) of ^{177}Lu-rituximab, of ^{177}Lu-lilotomab, of the non-specific ^{177}Lu-cetuximab or to unlabelled mAbs (0-40μg/mL). A radiobiological model considering the contribution of cytotoxic effects of ^{177}Lu (radiation only) and of unlabelled antibody (mAb only) to the cytotoxicity of ^{177}Lu-mAbs was established. We next investigated in which B-cell NHL subtypes ^{177}Lu-lilotomab would be the most efficient and how biological (genetic background, cell cycle, apoptosis) and/or physical (tumour absorbed doses) parameters could affect the final therapeutic outcome. *In vivo*, mice bearing subcutaneous Ramos or DOHH2 tumour xenografts, were treated at MTA of ^{177}Lu-mAbs and tumour growth was monitored. Organ and tumour absorbed doses were determined according to MIRD formalism. **Results:** We showed in the three lymphoma cell lines that unlabelled rituximab was more cytotoxic than lilotomab. When antibodies were radiolabeled, ^{177}Lu-lilotomab was as cytotoxic as ^{177}Lu-rituximab in the radiosensitive DOHH2 cells, but not in the most radioresistant Ramos cells. The higher response to ^{177}Lu-lilotomab in DOHH2 cells than in Ramos cells was mainly mediated by lack of G2/M cell cycle arrest followed by strong induction of apoptosis in DOHH2 cells. Inhibition of signal pathways involved in cell cycle control radiosensitized Ramos cells. These results were supported by *in vivo* data. ^{177}Lu-lilotomab was as efficient as ^{177}Lu-rituximab in Ramos tumour xenograft models only if tumour absorbed radiation dose was increased over a certain

limit. Conversely, in DOHH2 tumour xenografts, ^{177}Lu-lilotomab was as efficient as ^{177}Lu-rituximab for similar absorbed radiation doses, although lilotomab was less efficient than rituximab. **Conclusion.** A radiobiological approach identified the parameters determining ^{177}Lu-lilotomab therapeutic efficacy in different subtypes of lymphoma.

OP-055

Internal exposure of [131]I - potential biomarkers and functional analysis for long-term effects in thyroid

M. Larsson[1], N. Rudqvist[1], J. Spetz[1], B. Langen[1], T. Parris[2], K. Helou[2], E. Forssell-Aronsson[1]; [1]Department of Radiation Physics, Institute of Clinical Sciences, Sahlgrenska Cancer Center, Sahlgrenska Academy, Gothenburg, SWEDEN, [2]Department of Oncology, Institute of Clinical Sciences, Sahlgrenska Cancer Center, Sahlgrenska Academy, Gothenburg, SWEDEN.

Aim: [131]I is a commonly used isotope in radiotherapy of different diseases, such as thyroid cancer and hyperthyroidism (^{131}I iodide), neuroblastoma, pheochromocytoma and paraganglioma (^{131}I-MIBG), and with ^{131}I-labelled monoclonal antibodies. However, there is a lack of knowledge of the long-term effects on thyroid tissue, after treatment with ^{131}I-containing radiopharmaceuticals. The aim of the present study was to identify biomarkers for long-term effects of ^{131}I exposure of the thyroid, related to thyroid function and cancer, using rats as a model system. **Materials and Methods:** Young male Sprague Dawley rats (5w) were i.v. injected with 0, 0.5, 5.0, 50 and 500 kBq [131]I ($D_{thyroid}$ = 0-10 Gy). The rats were killed 9 months after injection and thyroid and blood samples were collected. Microarray analysis (Agilent) was performed on RNA isolated from thyroid. Differentially expressed transcripts and associated GO-terms were identified using Nexus Expression 3.0. Proteins from thyroid and blood samples were analyzed by LC-MS/MS. For functional annotation of proteins, GO-term association was performed using DAVID bioinformatics research tool. Canonical pathway, function and diseases, and upstream regulation analysis was performed using Ingenuity Pathway Analysis (IPA) software. **Results:** The IPA and GO-term analyses showed a difference in biological effects dependent on dose and tissue type. In the IPA analysis, LC-MS/MS-data from thyroid samples had the most significant influence on both canonical pathways, biological functions and upstream regulators. Most of the significantly regulated canonical pathways were up-regulated and the majority were only present in one dose group, but NGF2-mediated oxidative stress response was present in three of the dose groups. In the biological functions and diseases analysis, an association with features regarding cell development and survival was seen. Only a few up-stream regulators were significantly regulated, including PPARG which was seen in all four test groups. PPARG is not found in normal thyroid and may indicated malfunction and potentially certain types of thyroid cancer. In the GO-term analysis, metabolism (nucleic acid-related response) showed the highest response to ^{131}I irradiation. On the other hand, little or no response to DNA integrity was seen. **Conclusion:** In conclusion, effects on thyroid function depend on the administrated dose and are not strictly proportional with dose. A potential thyroid function candidate marker is the up-stream regulator PPARG, but further tissue analysis is necessary to fully evaluate its potential as a cancer biomarker.

OP-056

Contribution of macro and micro-dosimetry in alphatherapy

N. Benabdallah[1], M. Bernardini[2], D. Franck[1], C. de Labriolle-Vaylet[3,4], W. Bolch[5], A. Desbrée[1]; [1]IRSN - Institute for Radiological Protection and Nuclear Safety, Fontenay aux Roses, FRANCE, [2]Georges Pompidou European Hospital, Paris, FRANCE, [3]UPMC, University of Paris 06 Biophysics, Paris, FRANCE, [4]Trousseau Hospital, Paris, FRANCE, [5]Department of Biomedical Engineering, University of Florida, Gainesville, FL, UNITED STATES OF AMERICA.

Purpose: In nuclear medicine, the injected activity needs to be personalized for each patient. For alpha-particle emitting radiopharmaceuticals, a personalized dosimetry is challenging because of the short range of alpha particles. The aim of this work was to develop tools to optimize patient-specific dosimetry in alphatherapy. To that aim, the study focuses on [223]Ra-dichloride (Xofigo®) used for the treatment of patients with castration-resistant prostate cancer metastasized to bones. **Methods:** First, quantitative imaging must be performed to characterize the macroscopic biodistribution of the radiopharmaceutical in the patient body. As SPECT imaging gives a better quantification than planar imaging, the possibility of quantitative SPECT imaging of [223]Ra was investigated for the first time. Several phantoms studies were performed in order to determine the best SPECT/CT imaging protocol, according to the MIRD Pamphlet No. 23. Then, as bone marrow is an organ at risk for these treatments, the dose to this region is needed. Current dose models do not account for energy or bone-site dependence as shown by alpha-particle absorbed fractions given in ICRP Publication 30. Using the most realistic voxelized model of the skeleton for adult male that describes the bones at a microscopic scale, developed by the University of Florida, and MCNP6 Monte Carlo code, the S-values to the two radiosensitive tissues, endosteum and red bone marrow, have been calculated for several source tissues such as the trabecular bone, the yellow marrow or the cortical bone. Furthermore, as the marrow cellularity is dependent of the age, the evolution of alpha absorbed fraction to the red bone marrow with the marrow cellularity was studied. Finally, the short range of alpha-particles relative to the typical scale of human organ dimensions can lead to a highly non-uniform irradiation of the target volume. The microdistribution of [223]Ra was investigated in skeletally mature mice and metastasis models, using autoradiography. **Results:** Quantification accuracies of approximately 4% for a 5.6mL sphere containing 20kBq/mL can be expected. This protocol has been implemented in a new clinical trial for treatment of patients with bone metastases in renal cell carcinoma. Differences, up to 50% when considering the trabecular bone surface as source and red bone marrow as target, were observed between our model and the ICRP Publi-

cation 30. The autoradiography images will be used to correlate absorbed dose to therapeutic response. **Conclusion:** This study investigates different aspects of the ^{223}Ra dosimetry and offers tools to optimize dosimetry for other alpha emitters.

OP-057

Monte-Carlo modelling of energy deposition within a realistic 3D model of follicular lymphoma

J. Bordes[1,2], S. Incerti[3,4], C. Rossi[1,2,5], J. Bordenave[1,2], C. Bezombes[1,2], M. Bardies[1,2], M. Bordage[1,2]; [1]Centre de Recherches en Cancérologie de Toulouse, Toulouse, FRANCE, [2]UMR 1037 Inserm/UPS, Toulouse, FRANCE, [3]Centre d'Etudes Nucléaires de Bordeaux-Gradignan, Gradignan, FRANCE, [4]CNRS / IN2P3 / Université de Bordeaux, Gradignan, FRANCE, [5]Service d'hématologie clinique, CHU le Bocage, Dijon, FRANCE.

Aim: Small-scale dosimetry modelling often considers spherical tumours and uniform source distributions. However, geometry and radiopharmaceutical distribution is known to impact energy deposition in targeted radionuclide therapy (Arnaud *et al.* NIMB 316:227-233 2016). In this study, we used an innovative 3D model of follicular lymphoma and rituximab distributions to model energy that would be imparted by different radioisotopes in a context of radioimmunotherapy (RIT). **Material and methods:** The starting point of this study is a 3D model of follicular lymphoma (Gravelle *et al.* Am J Pathol 184:282-95 2014), named Multicellular Aggregates of Lymphoma Cells (MALC). MALCs were incubated with rituximab, an anti-CD20 monoclonal antibody used in the treatment of non-Hodgkin lymphomas. Geometry, antibody location and concentration were extracted from single plan illumination microscopy. Assuming antibody labelling with Auger (^{111}In and ^{125}I) or β- (^{90}Y, ^{131}I and ^{177}Lu) emitters, we simulated energy deposition in MALCs using two Monte-Carlo codes. Interactions of low-energy electrons (Auger) were simulated using the Geant4-DNA toolkit with the CPA100 set of physics models recently validated from 10 eV to 250 keV (Bordage *et al.* Physica Medica 32:1833-1840 2016), whereas β- emitters were simulated using the Geant4 toolkit with the Livermore set of physics models, validated from 250 eV to 1 GeV. For each isotope, 10^6 decays were considered. **Results:** Rituximab was concentrated in the periphery of a 1 mm diameter MALC. For Auger emitters, energy deposition was mostly local, with 67% vs. 30% of voxels hit for ^{111}In vs. ^{125}I, respectively. In comparison, β- emitters deposited energy inside at least 96% of the MALC's voxels. Within the MALC, ^{111}In and ^{125}I deposited 22 and 19 keV/decay, whereas ^{131}I, ^{177}Lu and ^{90}Y deposited 83, 82 and 66 keV/decay, respectively. This results from β- emitters releasing more energy per decay than Auger emitters, but also from the relationship between radiation range and MALC geometry: for example, despite higher emitted energy, ^{90}Y deposits less energy per decay inside the MALC than the other ß emitters. **Conclusion:** This study combined realistic geometry and vector distribution with Monte-Carlo modelling of ionizing radiation interactions to evaluate the potential of several isotopes for NHL RIT. In the tested configuration, β- emitters delivered energy inside nearly all the voxels of the MALC. In terms of energy depos-

ited in the targets, ^{131}I and ^{177}Lu proved more effective than ^{90}Y. Future work will consider MALCs of different sizes and different antibody repartitions.

OP-058

Voxel-based multi-model fitting method for modelling time activity curves in SPECT images

D. Sarrut, Sr.[1], A. Halty[1], J. Badel[2], L. Ferrer[3], M. Bardies[4]; [1]CREATIS / CLB, Lyon, FRANCE, [2]CLB, Lyon, FRANCE, [3]ICO / CRCINA, Nantes, FRANCE, [4]CRCT, Toulouse, FRANCE.

Purpose: Estimating the biodistribution and the pharmacokinetics from time-sequence SPECT images on a per-voxel basis is useful for studying activity non-uniformity or computing absorbed dose distributions by convolution of voxel kernels or Monte-Carlo radiation transport. Current approaches are either region-based, thus assuming uniform activity within the region, or voxel-based but using the same fitting model for all voxels. **Methods:** We propose a voxel-based multi-model fitting method (VoMM) that estimates a fitting function for each voxel by automatically selecting the most appropriate model among a predetermined set with Akaike criteria. This approach can be used to compute the time integrated activity (TIA) for all voxels in the image. To control fitting optimization that may fail due to excessive image noise, an approximated version based on trapezoid integration, named restricted method, is also studied. From this comparison, the number of failed fittings within images was estimated and analyzed. Numerical experiments were used to quantify uncertainties and feasibility was demonstrated with real patient data. **Results:** Regarding numerical experiments, root mean square errors of TIA obtained with VoMM were similar to those obtained with bi-exponential fitting functions, and were lower (< 5 % vs > 10%) than with single model approaches that consider the same fitting function for all voxels. Failure rates were lower with VoMM and restricted approach than with single-model methods. On real clinical data, VoMM was able to fit 90% of the voxels and led to less failed fits than single-model approaches. On regions of interest (ROI) analysis, the difference between ROI-based and voxel-based TIA estimations was low, less than 4%. However, the computation of the mean residence time exhibited larger differences, up to 25%. **Conclusions:** The proposed voxel-based multi-model fitting method, VoMM, is feasible on patient data. VoMM leads to similar organ-based TIA estimations as conventional ROI-based method. However, for pharmacokinetics analysis, studies of spatial heterogeneity or voxel-based absorbed dose assessment, VoMM could be used preferentially as it prevents model overfitting.

OP-059

A Monte Carlo method to evaluate confidence intervals of time-integrated activity curve in molecular radiotherapy

B. Cassano[1], A. Napolitano[1], M. Longo[1], E. Genovese[1], S. Donatiello[1], T. Insero[1], E. Richetta[2], M. Pasquino[2], M. Stasi[2], M. Pacilio[3], V. Cannatà[1]; [1]Medical Physics Unit, Bambino Gesù Children's Hospital, Rome, ITALY, [2]Medical Physics Department, AO Ordine Mauriziano

di Torino, Turin, ITALY, [3]Medical Physics Department, Azienda Ospedaliera Universitaria Policlinico Umberto I, Rome, ITALY.

Purpose/Introduction: In molecular radiotherapy (MRT) calculating biokinetic parameters plays a crucial role to assess the absorbed dose to lesions or organs at risk. The assessment of the time-integrated activity curve is affected by fitting model, number of acquired points and sampling timing. The main purpose of this work was to introduce a methodology which is able to estimate error associated to Time-Integrated Activity Coefficient (TIAC) and mainly due to the uncertainty in fitting procedure. This method was applied to whole-body and blood biokinetic data of patients affected by metastatic differentiated thyroid cancer (mDTC) enrolled in two different Italian Hospitals. **Subjects & Methods:** The Monte Carlo method is implemented in matlab and relied on the generation of a large number of data-set based on root mean square error (RMSE) associated to the fit model. To compute the confidence intervals of the time-integrated activity coefficient, physical constraints on fit parameters were introduced. Biokinetic data (time acquisition window of about 50 hours) of 35 patients affected by mDTC and administered with two different radionuclides (^{123}I and ^{131}I) were analyzed, by fitting all data sets with a mono-exponential curve. Two classes of data sets were considered: Low Number of Points (LNP) and High Number of Points (HNP) time-activity data, consisting of 4 and 20 points respectively. As the confidence intervals of TIAC are not symmetric respect to the best-fit values, both upper and lower bandwidths were calculated. The correlation between RMSE and bandwidths was also investigated. **Results:** The bandwidths assessed ([mean lower, mean upper]) was [-14.3, +17.1]% for LNP and [-9.3, +10.6]% for HNP. The RMSE is demonstrated to be correlated to the bandwidths with two different power laws for LNP and HNP. For LNP the R^2 was 0.98 and 0.97 for lower and upper band respectively while for HNP the R^2 was 0.94 and 0.97 for lower and upper band. **Discussion/Conclusion:** The method is very simple to be implemented and it has the advantage of high flexibility when there is need to impose physical constraints to the fitting. As expected, the bandwidths decrease when considering data with a larger number of points. Moreover, having our data similar time window acquisition, the RMSE itself has been observed as a good predictor of the bandwidths as computed with the present method. The proposed method is also versatile and can be employed to calculate the confidence interval of time activity data, regardless instrumentation and administered radionuclides

OP-060

Validation of a voxel-dosimetry and radiobiology tool for patient specific peptide receptor radionuclide therapy

D. Finocchiaro[1,2], S. Berenato[3], E. Grassi[1], F. Fioroni[1], G. Castellani[2], N. Lanconelli[2], A. Versari[4], E. Spezi[3], M. Iori[1]; [1]Medical Physics Unit, Arcispedale Santa Maria Nuova-IRCCS, Reggio Emilia, ITALY, [2]Dept. of Physics, University of Bologna, Bologna, ITALY, [3]School of Engineering, Cardiff University, Cardiff, UNITED KINGDOM, [4]Nuclear Medicine Unit, Arcispedale Santa Maria Nuova-IRCCS, Reggio Emilia, ITALY.

Purpose: In this work VoxelMed2.0 (VM) , the voxel dosimetry tool developed at ASMN-IRCCS, is validated in a phantom and patient study, in comparison with Raydose (Monte Carlo based software, Cardiff University) and OLINDA. The aim is to assess the importance of estimating an accurate voxel level absorbed dose and biological effective dose (BED) for individualized therapy. **Subjects & Methods:** The phantom validation was performed with: a homogeneously 177Lu-filled cylindrical phantom (Jaszczak, Data Spectrum Corporation), an anthropomorphic phantom (Liqui-Phil™,The Phantom Laboratory) with organ shaped inserts (liver,spleen,pancreas,kidneys) and two cylindrical phantoms with in total 11 inserts different for shape and volume (toroidal 3,3,10ml; ellipsoidal 4,15,28ml; cylinder-like 28,29ml and pyramid-like 29,30,31ml). Every phantom was scanned once and the time-activity-curve obtained by 177Lu physical decay. For the clinical validation 50 patients were scanned 5 times, after a therapeutic administration of 177Lu. Images were acquired with a Siemens Symbia T2 SPECT-CT. The percentage difference (PD) between VoxelMed2.0 and either of the two reference software was evaluated for mean dose. Mean BED for patients and dose-volume histograms (DVH) of phantoms also were evaluated. **Results:** PDs for homogeneous phantom were: -12% VM vs OLINDA, and -5% VM vs Raydose. PDs (VM-Olinda/VM-Raydose) were: (-29%/-31%) toroid-3ml and (-23%/-16%) toroid-10ml. Mean PDs (VM-Olinda[SD]/VM-Raydose[SD]) for the other inserts: (-19%[2%]/-8%[20%]) ellipsoid, (-21%[0%]/3%[4%]) pyramid-like, (-21%[1%]/4%[8%]) cylinder-like. PD (VM-Olinda/VM-Raydose) for organ inserts were: -14%/-8% pancreas, -13%/-5% kidney, -12%/-6% spleen, -12%/-6% liver. Dose maps obtained by the two voxel-dosimetry software showed visually similar dose distributions, and DVH showed similar slopes. As regards patients VoxelMed2.0 was compared with OLINDA, obtaining mean PD [SD]: -12%[10%] kidney, -5%[11%] liver and -9%[9%] for spleen. Variance analysis provided statistical difference in the dose measured for kidney and for liver (p-value 0.006 and 0.012), while no statistical difference for spleen (p-value 0.268). Similar PD remains for the BED calculations. **Conclusions:** In phantoms we obtained different dose values for the three software, most likely because of the different method of calculation. In particular differences were more pronounced for irregular geometries of VOI (i.e. toroidal), while there is a best accordance for homogenous and anthropomorphic phantoms. In general we observed the best agreement between VoxelMed and Raydose, while greater difference in respect to OLINDA. For patients the variance analysis between VoxelMed and OLINDA doses showed that the two populations are significantly different in case of kidney and liver, even if further investigations is required. Work supported by EMPIR-MRTDosimetry project(15HLT06), co-funded by EU's Horizon-2020-programme.

OP-061

Immunotargeting of Galectin-3 in thyroid orthotopic tumor models opens new challenges for thyroid cancer imaging and biological characterization in vivo

C. D'Alessandria[1], F. De Rose[1], M. T. Kuhlmann[2], M. Braeuer[1], S. Reder[1], S. Braesh-Andersen[3], A. Bartolazzi[4], M. Schwaiger[1]; [1]Klinikum rechts der Isar - Technical University of Munich, Munich, GERMANY, [2]European Institute for Molecular Imaging (EIMI), University of Münster, Münster, GERMANY, [3]Mabtech AB Research Laboratory, Stockholm, SWEDEN, [4]Pathology Research Laboratory, Sant'Andrea Hospital, University Sapienza, Rome, ITALY.

Introduction: The preoperative characterization of thyroid nodules is challenging. Thyroid scintigraphy with radioiodine provides functional information (cold or hot nodules) based on radio-iodine uptake, but fails to distinguish among benign and malignant lesions. Galectine-3 is expressed in well-differentiated thyroid carcinomas but not in normal thyrocites or benign nodules. Herein, we aimed to demonstrate the specificity of Galectin-3 immuno-targeting compared to radio-iodine imaging in thyroid orthotopic tumor models, which mimic the human condition. **Methods:** FRO82-1 and CAL62 carcinoma cells were chosen and characterized for Gal-3 and sodium/iodide symporter (NIS) expression via WB and qPCR. A anti-Gal3 F(ab')$_2$ fragment was generated from a rat mAb via pepsin digestion, functionalized with DFO-NCS, labeled with ^{89}Zr and characterized for binding and immunoreactivity on 2D cell cultures. Iodine-125 internalization studies using both cell lines were also performed. Binding of ^{89}Zr-DFO-F(ab')$_2$ anti-Gal3 and iodine-125 accumulation were evaluated on tumor spheroids. Thyroid orthotopic murine model were established by inoculation of FRO82-1 and CAL62 cells into the left thyroid lobe of athymic nude mice, and tumor growth was monitored weekly via US imaging. Mice were imaged by PET/CT after i.v. injection with Iodine-124 and later with ^{89}Zr-DFO-F(ab')$_2$ anti-Gal3, followed by biodistribution studies and immunohistochemistry analysis for Gal-3 and NIS expression. **Results:** FRO82-1 and CAL62 carcinoma cells were invariably Galectin-3 positive, while being NIS+ and NIS- respectively. ^{89}Zr-DFO-F(ab')$_2$ anti-Gal3 showed high stability, high affinity to Gal3 (K_d ~0.5 nM) and immunoreactivity (>75%) on 2D cell cultures and specific binding on tumor spheroids. Iodine-125 was internalized by FRO82-1 cells while background accumulation was measured for CAL62 cells, both in 2D and spheroids. *In vivo* PET/CT imaging showed excellent image contrast for ^{89}Zr-DFO-F(ab')$_2$ anti-Gal3 and signal associated to the orthotopic-implanted tumors. Iodine-124 signal was visible for FRO82-1 tumors (NIS+) with only background signal for CAL62 tumors (NIS-). Biodistribution studies for ^{89}Zr-DFO-F(ab')$_2$ anti-Gal3 revealed higher uptake in tumor-bearing thyroid lobe and no uptake in the healthy thyroid, due to Gal-3 expression in tumor-bearing left lobes and absence in tumor-free right lobes. Differential accumulation of iodine-124 was measured based on NIS expression. **Conclusions:** Using thyroid orthotopic models, we reproduced the clinical situation with *hot* (FRO82-1) and *cold* (CAL62) nodules, based on radio-iodine uptake. Specific and selective accumulation of ^{89}Zr-DFO-F(ab')$_2$ anti-Gal3 even in absence of radioiodine uptake was demonstrated. Translation of this method in clinical setting promises to improve and change the management of patients bearing thyroid nodules allowing tumor biological characterization *in vivo*.

Pretargeted radionuclide therapy of HER2-expressing SKOV-3 human xenografts using an Affibody molecule-based PNA-mediated pretargeting

M. Altai[1], K. Westerlund[2], M. Konijnenberg[3], B. Mitran[4], M. Oroujeni[1], M. de Jong[3], A. Eriksson-Karlström[2], A. Orlova[4], V. Tolmachev[1]; [1]Institute of Immunology, Genetics and Pathology, Uppsala, SWEDEN, [2]Division of Protein Technology, Royal Institute of Technology, Stockholm, SWEDEN, [3]Department of Nuclear Medicine and Radiology, Erasmus MC, Rotterdam, NETHERLANDS, [4]Division of Molecular Imaging, Uppsala, SWEDEN.

Aim: Targeting using radiometal-labelled affibody molecules is associated with high renal uptake and retention of radioactivity. Reducing kidney uptake of radioactivity by e.g. co-injecting Gelofusine or amino acids was inefficient. Pretargeting is a promising approach to overcome renal toxicity. We developed a pretargeting approach based on hybridization between two complementary peptide nucleic acids (PNAs). The primary targeting agent is $Z_{HER2:342}$-SR-HP1, an anti-HER2 affibody-PNA chimera containing HP1 PNA. The complementary PNA HP2 probe contains DOTA and can be labelled with a variety of radiometals. In the current study we optimized this pretargeting approach using ^{177}Lu and performed experimental therapy study. **Methods:** Tumour targeting of ^{177}Lu-HP2 was studied in mice bearing HER2-overexpressing SKOV-3 ovarian carcinoma xenografts preinjected with $Z_{HER2:342}$-SR-HP1 4, 8, or 16 h in advance. Dosimetry was evaluated and pre-clinical therapeutic study was assessed. **Results:** Tumour uptake of ^{177}Lu-HP2 (1 µg) 1h p.i. was 75-fold higher for the pretargeted (18.4±1 %ID/g) than the non-pretargeted group (0.23±0.08%ID/g). The tumour uptake of ^{177}Lu-HP2 (1 µg) 1h p.i. was 22±5, 21±3 and 18±1 %ID/g when mice were pre-injected with 50 µg $Z_{HER2:342}$-SR-HP1 at 4, 8 and 16 h respectively. Interestingly the kidney uptake decreased significantly from 16±6 %ID/g (when ^{177}Lu-HP2 was injected 4h p.i. of $Z_{HER2:342}$-SR-HP1) to 4±1 and 2.8±0.2 %ID/g (8 and 16 h post $Z_{HER2:342}$-SR-HP1 injection, respectively). The tumour-to-kidney ratio was the highest (ca.6), at 16 h post $Z_{HER2:342}$-SR-HP1 injection. ^{177}Lu-HP2 uptake in the tumour exceeded that in any other organ up to 216 h p.i. Estimated absorbed radiation doses (Gy/MBq) to the tumour per single treatment cycle was ca. 1.08 Gy/MBq, 5-fold higher than the kidney dose of 0.21 Gy/MBq. Mice (n=10/group) were treated weekly (for 6 weeks) with iv doses of (A) PBS, or (B) 100µg $Z_{HER2:342}$-SR-HP1, or (C) 3.5 µg, 16 MBq^{177}Lu-HP2, or (D) preinjected 100µg $Z_{HER2:342}$-SR-HP1 followed 16 h later by 3.5 µg, 16 MBq^{177}Lu-HP2 (corresponding to 6 x 17 Gy tumour dose). Group D demonstrated significant inhibition of tumour growth. The median survival was 37 d for A, 32 d for B, 37 d for C and 66 d for D. Treatment was not associated with the loss of body weight, which indicates its moderate toxicity at a kidney dose of 6 x 3.3 Gy. **Conclusion:** The use of affibody-based PNA-mediated pretargeting can deliver high dose to tumours while sparing kidneys. Experimental therapy studies showed clear improvement of survival in treatment group compared to control groups.

OP-063

Immuno-PET imaging for PD-L1 expression in non-small cell lung cancer xenograft

*D. Li, S. Cheng, S. Zou, D. Zhu, **X. Zhu**; Tongji Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, CHINA.*

Programmed cell death protein-1 and programmed cell death ligand-1 (PD-1/PD-L1) axis, known as a main immune checkpoint inhibitory pathway, plays a critical role in cancer immunotherapy. Antibodies targeting the PD-1/PD-L1 pathway have shown durable tumor regression and improved patient survival in the treatment of a broad set of cancer subtypes, such as Hodgkin lymphoma, non-small cell lung cancer, melanoma, renal cell carcinoma, et al. Patients with tumors expressing PD-L1 are most likely to respond to anti-PD-1/PD-L1 treatment. The aim of this study is to develop a novel immune-PET technique to non-invasive determine and timely monitor tumor PD-L1 expression in vivo, which could help to select the patients who are most likely to benefit from anti-PD-1/PD-L1 treatment and evaluate the prognosis. **Methods**: KN035, an anti-PD-L1 heavy chain antibody selected from a large camel naïve phage display Nanobody library, was labeled with radionuclide 89Zr through conjugated to pisothiocyanatobenzyl-desferrioxamine (Df-Bz-NCS). The resulting probe, 89Zr-Df-KN035, was then evaluated by in vitro cell uptake and blocking studies using PD-L1 positive cell lines, human lung adenocarcinoma cell line A549. Next, serial immnuo-PET (at 1, 6, 24, 48, 72 and 120 h post-injection respectively, n=4) and biodistribution studies were performed in nude mice bearing A549 tumor xenografts to evaluate in vivo performance of 89Zr-Df-KN035. Furthermore, the mice were received 100 mg/kg of gefitinib by intragastric administration once a day for 21 days (n=6). After that, immnuo-PET was performed at 48 h post-injection of 89Zr-Df-KN035. **Results**: Serial immnuo-PET imaging revealed that A549 tumors xenografts were clearly visible from 24h to 120h after radiotracer injection, while markedly reduced accumulations of 89Zr-Df-KN035 were noticed in blocking group. Moreover, tumor uptakes of 89Zr-Df-KN035 decreased after gefitinib therapy, confirmed by the PD-L1 expression with IHC. **Conclusion**: 89Zr-Df-KN035 demonstrates promise for use as an immuno-PET agent to image tumor PD-L1 expression in living system, as well as monitor the change of tumor PD-L1 expression in real time after therapy, which might be helpful in selection of patients with NSCLC performing anti-PD-1/ anti-PD-L1 antibody therapy.

OP-064

SPECT imaging of carbonic anhydrase IX with 111In-girentuximab-F(ab')2 as radiotracer in head and neck xenografts

F. J. Huizing, B. A. W. Hoeben, S. Heskamp, J. Bussink, O. C. Boerman; Radboudumc, Nijmegen, NETHERLANDS.

Introduction: Tumor hypoxia is a major cause of radio- and chemoresistance in solid tumors. Carbonic anhydrase IX (CAIX) is an endogenous hypoxia-related marker strongly associated with poor outcome, which makes it an important prognostic and predictive marker. Assessment of CAIX expression may allow patient selection and monitoring for hypoxia- or CAIX-targeted treatment combined with radiotherapy. The aim of this study was to validate and optimize 111In-girentuximab-F(ab')$_2$ SPECT for imaging of CAIX expression in head and neck tumor models. **Methods:** The optimal timing and protein dose for imaging were determined in athymic nude mice with subcutaneous SCCNij153 xenografts (head and neck squamous cell carcinoma with high CAIX expression). SPECT/CT images were acquired of mice with SCCNij202 and SCCNij153 xenografts. The non-specific tumor-targeting property of 111In-girentuximab-F(ab')$_2$ was determined by blocking the specific uptake with co-injection of unlabeled G250 IgG. Tracer uptake was determined using SPECT/CT, ex vivo radioactivity counting and autoradiography of tumor sections. Spatial correlation between immunohistochemical staining of CAIX expression and tracer uptake on autoradiography was determined. **Results:** Optimal SPECT/CT images were obtained at 24 hours after injection of the tracer. A protein dose of 10 μg resulted in the highest tumor-to-blood ratio after 24 hours post-injection. Ex vivo measurements showed a tumor uptake of 3.0 ± 0.9 %ID/g, and a tumor-to-blood ratio of 31:1. Unlabeled G250 IgG markedly reduced tumor uptake to 1.1 ± 0.3 %ID/g. Immunohistochemistry and autoradiography images of tumor sections showed a distinct spatial correlation between localization of the tracer and CAIX expression. **Conclusion:** 111In-girentuximab-F(ab')$_2$ shows specific targeting of CAIX-expression in head and neck squamous cell carcinoma xenografts. For optimal pre-clinical imaging in mice, a tracer protein dose of 10 μg should be administrated 24 hours before scanning. These results indicate that 111In-girentuximab-F(ab')$_2$ is a promising tracer for imaging of hypoxia-induced CAIX expression. In ongoing studies we will assess the tracer's applicability for treatment selection and monitoring of hypoxia response to therapy.

OP-065

Ab-1881, An Anti-PDL1 Immune Checkpoint Inhibitor Serves as A Theranostic Agent for Cancer Immunotherapy

*M. Xu, Y. Han, **Z. Liu**; Peking University, Beijing, CHINA.*

Objective: Inhibiting PD-1/PD-L1 pathway using antiPD-1 or antiPD-L1 antibody has shown great success on cancer treatment. However, only 20~25% cancer patients exhibit positive response to PD-L1 immunotherapy. Though immunohistochemistry (IHC) is the gold standard for patient classification, a non-invasive method is highly favored for clinical diagnosis. Herein, we report a new antiPD-L1 monoclonal antibody (Ab1881), of which Copper-64 labelled derivative exhibited significantly different tumor uptake on PD-L1 positive and negative types of xenografts. In addition, the xenografts of high Ab1881 uptake demonstrated notable therapeutic efficacy, while the xenografts of low Ab1881 uptake kept growing rapidly till scarification, demonstrating a strong correlation between PET imaging and therapeutic efficacy. **Method:** Ab1881 was

conjugated with a bifunctional chelator 2-S-(4-Isothiocyanato-benzyl)-1,4,7-triazacyclononane-1,4,7-triacetic acid (p-SCN-Bn-NOTA) to give NOTA-Ab-1881. Copper-64 radiolabeling was conducted in sodium acetate buffer (pH=4), and quality control was performed by radio-HPLC equipped with size-exclusion column. The metabolic stability of ^{64}Cu-NOTA-Ab1881 was assessed under both *in vitro* and *in vivo* conditions. PET imaging and bio-distribution studies were performed in mice bearing MC38 (PDL1 positive) and 4T1 (PDL1 negative) xenografts on the left and right shoulder, respectively. Ab1881 treatment was performed 3 days a time, 0.25 mg for each therapy. **Result:** Cu-NOTA-Ab1881 and Ab1881 bound to PD-L1 with the binding affinity of 0.47 ± 0.12 nM and 0.92 ± 0.33 nM, respectively. ^{64}Cu-NOTA-Ab1881 exhibited 4.7 ± 2.1, 10.3 ± 3.2, 14.3 ± 4.1, 19.7 ± 3.7 %ID/g uptake in MC38 xenografts at 2.0, 4.0, 12.0, 24.0 hours post injection, respectively. Meanwhile, ^{64}Cu-NOTA-Ab1881 exhibited 3.7 ± 1.3, 4.3 ± 1.2, 5.3 ± 2.1, 6.8 ± 2.7 %ID/g uptake in 4T1 xenografts at 2.0, 4.0, 12.0, 24.0 hours post injection, respectively. The rest of radiotracer was excreted mainly through hepatobiliary system, and liver uptake reached to maximum at around 12 hours post injection, which is 17 ± 4.3%ID/g. In regards to treatment, xenografts of MC38 kept the same size if did not shrink at day 21 post therapy. In contrast, at day 21, xenografts of 4T1 were 12.7 ± 1.2 times larger than them of day 0. **Conclusion:** A Copper-64 labelled Ab1881 was reported that successfully distinguished PD-L1 positive and negative xenografts in mouse model with PET imaging. Moreover, Ab1881 also demonstrate impressive therapeutic efficacy, which is highly correlated to the tumor uptake of its radioactive derivative.

OP-066

Monitoring tumor PD-L1 expression with microSPECT/CT during radiotherapy

S. Heskamp, J. D. M. Molkenboer-Kuenen, G. W. Sandker, P. J. Wierstra, J. Bussink, O. C. Boerman; Radboud University Nijmegen Medical Centre, NIJMEGEN, NETHERLANDS.

Introduction: Programmed death-1 (PD-1) is expressed by T-cells and is a major co-inhibitory immune checkpoint. Its ligand PD-L1 is expressed on tumor cells. By upregulating PD-L1, tumors are capable of escaping immune recognition and attack. Clinical trials with anti-PD-1/PD-L1 immune checkpoint inhibitors (ICI) have shown impressive and durable antitumor activities. However, only a subgroup of patients benefit from these drugs. To use ICI more effectively, rational treatment combination strategies are warranted. Imaging of tumor PD-L1 expression during conventional anti-cancer treatment may aid in finding optimal treatment combination strategies. Here, we studied the potential of PD-L1 microSPECT/CT imaging to monitor changes in PD-L1 expression during radiotherapy. **Material and Methods:** Anti-murine PD-L1 antibody was radiolabeled with ^{111}In and in vitro binding was assessed using CT26 (low PD-L1), LLC1 (low PD-L1), and B16F1 (high PD-L1) tumor cells. Mice were injected s.c. with CT26, LLC1, or B16F1 cells in the right hind leg. Tumors were irradiated with a single dose of 10 Gy. Control mice were not irradiated. One day after irradi-

ation, mice received 25 MBq ^{111}In-labeled anti-PD-L1 antibody (30 μg), followed by microSPECT/CT imaging and ex vivo bio-distribution one day post injection. Tumors were stained for PD-L1 by immunohistochemistry. **Results:** ^{111}In-labeled anti-PD-L1 showed specific binding to CT26 (5.7 ± 0.5%), LLC1 (10.7 ± 0.3%), and B16F1 (26.8 ± 1.0%) cells in vitro. MicroSPECT/CT showed increased uptake of the radiolabeled anti-PD-L1 antibody in irradiated tumors versus non-irradiated CT26 tumors (23.4 ± 2.1 %ID/g versus 15.2 ± 2.7 %ID/g, p=0.003). In LLC1 and B16F1 tumors, the difference in tracer uptake between irradiated versus non-irradiated tumors was not significant (LLC1: 14.0 ± 1.7 versus 11.7 ± 2.5 %ID/g, B16F1 17.0 ± 0.2 versus 16.3 ± 3.4 %ID/g). Immunohistochemical staining showed that the increased tumor uptake in CT26 tumors was related to increased PD-L1 expression. **Conclusion:** These studies demonstrate that PD-L1 microSPECT/CT can be used to monitor the dynamic expression levels of PD-L1 in syngeneic murine tumor models during radiotherapy. This technique can potentially be used to monitor PD-L1 during conventional anti-cancer treatment to find optimal ICI treatment combination strategies.

OP-067

PET Imaging of Programmed Cell Death Protein 1 (PD-1) in a Humanized Mouse Model of Lung Cancer

W. Cai, D. Jiang, C. G. England, T. E. Barnhart; University of Wisconsin-Madison, Madison, WI, UNITED STATES.

Objectives: PET imaging of human programmed cell death protein 1 (PD-1) could have profound clinical utility in personalized/precision cancer immunotherapy. Therefore, this study investigates a novel radiotracer targeting PD-1 (^{89}Zr-Df-Nivolumab) for mapping the biodistribution of activated PD-1-expressing T-cells (which is expected to localize to the tumor) in a humanized murine model of lung cancer. **Methods:** Nivolumab (FDA-approved for PD-1 targeted cancer therapy) was conjugated to p-SCN-deferoxamine and radiolabeled with Zr-89 to form ^{89}Zr-Df-Nivolumab. Humanized tumor-bearing mice were created by first implanting one million A549 cells into 6-8 week-old non-obese diabetic severe combined immunodeficient (SCID) gamma (NSG) mice. Once the tumor reached 1-2 mm in diameter, mice were intravenously injected with human peripheral blood mononuclear cells (hPBMCs) to form PBL tumor-bearing mice. Two weeks after injection of hPB-MCs, mice were injected with ^{89}Zr-Df-Nivolumab for serial PET imaging. Region-of-interest (ROI) analyses of the images and ex vivo biodistribution studies were performed to determine tracer uptake in major organs/tissues and quantitative results were given as percentage injected dose per gram of tissue (%ID/g). Fluorescence immunohistochemistry was performed to assess the expression of PD-1 and CD3 (T-cell markers) in excised tissues. **Results:** The expression of human PD-1 was investigated in three groups by injection of ^{89}Zr-Df-Nivolumab, including humanized tumor-bearing mice (PBL-A549) and non-humanized tumor-bearing mice (NSG-A549). In PBL-A549 mice, tracer accumulation in the tumor was 6.93±1.21 and 9.85±2.74 %ID/g at 72 and 168 h post-injection. ^{89}Zr-Df-Nivolumab uptake in

the tumor of non-humanized NSG-A549 mice was significantly lower at 5.35±0.48 and 3.88±0.38 %ID/g at the same time points, suggesting that the accumulation was nonspecific due the significant decrease from 72 to 168 h. To further investigate human PD-1 specificity of [89]Zr-Df-Nivolumab, a nonspecific tracer ([89]Zr-Df-IgG) was injected into PBL-A549 mice. As expected, tumor uptake was low with the maximum signal of 3.08±0.40 %ID/g at 72 h post-injection. *Ex vivo* biodistribution validated these findings with PBL-A549 mice showing the highest tumor uptake. Confocal imaging of tissue sections revealed high CD3 and PD-1 expression in the tumor, spleen, and lung of PBL-A549 mice, indicative of PD-1-expressing T-cells. Minimal signal was found in the tissues from NSG-A549 mice. **Conclusion:** [89]Zr-Df-Nivolumab was successfully used to monitor the distribution of PD-1-expressing T-cells in humanized mouse models of lung cancer. This tracer holds great promise to aid in further understanding of immune checkpoint blockade therapy and the development of future PD-1-targeted imaging strategies.

OP-068a

Radiocobalt-labeled anti-HER1 affibody molecule DOTA-$Z_{EGFR:2377}$ for imaging of low HER1 expression in prostate cancer pre-clinical model

B. Mitran[1], J. Garousi[1], M. Rosestedt[1], E. Lindström[1], K. G. Andersson[2], S. Ståhl[2], J. Löfblom[2], V. Tolmachev[1], A. Orlova[1]; [1]Uppsala University, Uppsala, SWEDEN, [2]KTH-Royal Institute of Technology, Stockholm, SWEDEN.

Aim: Expression of human epidermal growth factor receptor type I (HER1) in prostate cancer (PCa) is associated with disease progression towards castration resistance. These receptors are potential targets for second line therapy in PCa and imaging of their expression might serve for patient stratification and therapy monitoring. Imaging of HER1 in PCa is however challenging due to the relatively low receptor expression and endogenous expression in many healthy organs (e.g. liver and intestinal walls). Earlier, we have demonstrated that imaging contrast could be improved by (i) optimization of injected protein dose and (ii) by extending the time between administration and imaging. Using of PET should further improve imaging sensitivity. The aim of this study was to prove the hypothesis that radiocobalt labeled affibody molecule DOTA-$Z_{EGFR:2377}$ could be used for imaging of low expression of HER1 in PCa. **Methods:** Cobalt-57 was used as a surrogate to positron emitter cobalt-55 (T1/2=17.5 h). Affinity and cellular processing of cobalt labeled affibody DOTA-$Z_{EGFR:2377}$ was studied using PCa cell line DU145 (2x10[5] receptors/cell). The biodistribution pattern of [57]Co-DOTA-$Z_{EGFR:2377}$ in DU145 xenografted mice was compared (i) after the injection of 35 and 10 μg of conjugate and (ii) at 3, 7 and 24 h pi of 10 μg of conjugate. **Results:** Radiocobalt labeled affibody DOTA-$Z_{EGFR:2377}$ retained subnanomolar affinity to HER1. The strong binding to low HER1-expressing PCa cells is important because [57]Co-DOTA-$Z_{EGFR:2377}$ demonstrated a very low internalization rate. Binding of the radioconjugate to cells decreased in the presence of anti-HER1 therapeutic mAb cetuximab. In vivo radioactivity uptake in blood, lungs, intestines and tumors was 2-fold high-er for mice injected with 10 μg of radioconjugate compared to the 35 μg group. However, the uptake in liver increased only by 60% after the 10 μg injection and the uptake in muscles was not changed. With time, the release of radioactivity from tumors was slower than from healthy tissues with the exception of kidneys. Tumor-to-organ ratios (T/O) increased with time after administration and, at 24 h pi, T/O were 3.5±0.2 for blood, 2.2±0.5 for colon, 7±1 for muscle, and 4.0±0.7 for bones (relevant organs for PCa imaging). High contrast images of PCa xenografts were obtained despite low HER1 expression. **Conclusion:** Radiocobalt-labeled DOTA-$Z_{EGFR:2377}$ is a promising imaging agent for the detection and monitoring of HER1 expression in PCa.

Preclinical evaluation of a single-chain variable anti TEM-1 fragment labeled with ^{111}In and [152]Tb

F. Cicone[1,2], T. Denoël[1], D. Viertl[1], G. Jakka[3], M. Irving[3], S. Dunn[3], T. Stora[2,4], N. P. van der Meulen[5], C. Müller[5], C. Vermeulen[5], U. Köster[6], K. Johnston[4], S. Gnesin[1], N. Riggi[7], N. Schaefer[1], G. Coukos[2,3], J. O. Prior[1,2]; [1]Nuclear Medicine, CHUV, Lausanne, SWITZERLAND, [2]Marie Sklodowska-Curie Innovative Training Network MEDICIS-PROMED, CERN, Geneva, SWITZERLAND, [3]Ludwig Center for Cancer Research, Lausanne, SWITZERLAND, [4]ISOLDE/CERN, Geneva, SWITZERLAND, [5]Paul Scherrer Institut, Villigen-PSI, SWITZERLAND, [6]Institut Laue-Langevin, Grenoble, FRANCE, [7]Molecular Pathology, CHUV, Lausanne, SWITZERLAND.

Purpose: Tumor Endothelial Marker-1 (TEM-1) is a promising target for immunotherapy, being upregulated by tumor cells, tumor vasculature and tumor-associated microenvironment. Our purpose was to test in-vitro and in-vivo a single-chain variable fragment directed against TEM1 (scFv78-Fc) labeled with either ^{111}In or [152]Tb, a positron-emitting CERN-produced radionuclide. **Methods:** [152]Tb was produced by proton-induced spallation of tantalum targets followed by mass separation, and purified using cation exchange chromatography. A concentrated solution of scFv78-Fc in pH 9.0 buffer and 10 eq. of CHX-A''-DTPA chelator were conjugated by heating at 42°C for 1 h, and then purified with a 50 kDa filter. [111]In or [152]Tb were complexed by additional 1 h heating at 42°C. The maximum binding sites (B_{max}) of purified TEM1 antigen and equilibrium dissociation constant (K_d) were determined with Scatchard plot. Immunoreactivity (IR) was determined by Lindmo plot. Two human cell lines, RD-ES (Ewing Sarcoma) and SK-N-AS (Neuroblastoma) were xenografted in NOD-SCID common gamma KO female mice. TEM1 expression was confirmed by fluorescence-activated cell sorting; antigen positivity was additionally proven by immunohistochemistry in excised tumors. Biodistribution was assessed 5, 24 and 48 h after i.v. injection of 0.1 MBq ^{111}In-CHX-A''-DTPA-scFv78-Fc (0.2 μg). The non-tumor antigenic sink was evaluated by co-injecting different amounts of unlabeled scFv78-Fc (range 0.2 - 200 μg). Additionally, after validation of [152]Tb activity quantification with a NEMA NU4 phantom, tumor-bearing mice were injected with 7 MBq [152]Tb-CHX-A''-DTPA-scFv78-Fc for μPET imaging and dosimetry (μSPECT/PET/CT Albira, Bruker). **Results:** Radiolabeling yield was >80% for both [111]In- and [152]Tb-labeled products (iTLC).

99% pure products were obtained after ultrafiltration. B_{max} and K_d were between 2-6 nmol/mg antigen and between 2-8 nM, respectively. IR was retained after radiolabeling (>70%). TEM1 expression was higher in SK-N-AS than in RD-ES cells. The best tumor-to-non-target ratios were obtained by co-injecting 25 µg of unlabeled CHX-A''-DTPA-scFv78-Fc. 24-h percent of injected ^{111}In-CHX-A''-DTPA-scFv78-Fc activity/g varied in the range 8-16, 16-22 and 10-14 for tumor, liver and kidneys, respectively. Tumor-to-background ratios increased slightly between 24 and 48 hours (average 24-h and 48-h tumor-to-liver ratios were 0.55 and 0.64, respectively). µPET imaging of [152]Tb-CHX-A''-DTPA-scFv78-Fc gave results comparable to those of biodistribution, showing enhanced tumor uptake and similar tumor-to-liver ratios. **Conclusion:** The scFv78-Fc anti-TEM1 was successfully labeled with ^{111}In and [152]Tb. Final products showed specific binding and preserved immunoreactivity. Biodistribution and µPET imaging showed favorable tumor uptake in two human tumor cell lines. TEM1 has promise as a target for radiolabeled antibodies.

Comparison study between 18F-Choline (FCH) and 68Ga-NODAGA-MJ9 (MJ9, Bombesin) PET-CT in prostate cancer initial staging

L. Haefliger[1], P. Mitsakis[1], T. Zilli[2], C. Pozzessere[1], J. Delage[3], H. Maecke[4], R. Mansi[4], R. Miralbell[2,5], N. Schaefer[1], J. Prior[1];

[1]Department of Nuclear Medicine, Lausanne University Hospital, Lausanne, SWITZERLAND, [2]Department of Radiation, Oncology, Geneva University Hospital, Geneva, SWITZERLAND, [3]Department of Pharmacy, Lausanne University Hospital, Lausanne, SWITZERLAND, [4]Department of Nuclear Medicine, University Hospital of Freiburg, Freiburg, GERMANY, [5]Institut Oncològic Teknon, Barcelona, SPAIN.

Purpose: To perform a one-to-one comparison of both ^{18}F-choline (FCH) and ^{68}Ga-NODAGA-MJ9 (MJ9) PET/CT in prostate cancer (PC) initial staging. **Material and Methods**: This prospective study included 15 Patients (age 71±6y [range 59-82y]) with histologically-proven prostate cancer with Gleason score 7±1 (6-9) and PSA 40±73 ng/ml (5.4-300 ng/ml). Initial staging PET/CT was performed both with FCH (200MBq) and MJ9 (200 MBq) 70 min p.i., within a period of 15 days (mean 1.5±3.5d, median 0d, range 0 to 13 day). Lesions were classified according to anatomical region (prostate primary lesion by lobe, lymph node and bone), and SUVmax was recorded in each location both for FCH and MJ9. **Results:** After this initial staging, 10 (66%) patients presented suspicious lymph nodes uptake for a total of 40 lymph nodes considered as metastatic (FCH 5.4±3.1 g/ml, MJ9 9.3± 8.9 g/ml). 2 patients (13%) presented bone metastasis with 4 lesions reported (FCH 9.5±4.7 g/ml, MJ9 4.6±3.6 g/ml). Primary prostate lesions uptake by lobe was inferior on FCH as compared to MJ9 (SUVmax 9.1±2.9 g/ml vs. 13.8±9.0 g/ml), but not significantly. In average, SUVmax, was 63% higher with MJ9 as compared to FCH in the prostate/lymph nodes, but lower for bone lesions (p=0.006). Compared to lymph node, FCH uptake was significantly higher in bone (p=0.048) and prostate (p=0.010), while MJ9 uptake was similar in all site. No significant correlation between FCH or MJ9 uptake and PSA, total Gleason score or age was found, except for higher MJ9 SUVmax in the prostate for higher Gleason score (p=0.003, test for trend). **Conclusion:** In initial prostate cancer staging, MJ9 uptake is significantly higher in the prostate and lymph nodes as compared to FCH, while FCH uptake was significantly higher than MJ9 in bone lesions. Our results show a potential interest for MJ9 in initial staging at the prostate and lymph node level.

OP-074

Clinical translation of bombesin antagonist based GRPR targeting PET radiotracer ^{68}Ga-NOTA-RM26

J. Zhang[1,2], G. Niu[2], X. Fan[3], L. Lang[2], H. Wu[4], J. Zang[1], G. Hou[1], F. Li[1], Z. Zhu[1], X. Chen[2]; [1]Department of Nuclear Medicine, Peking Union Medical College Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, CHINA, [2]Laboratory of Molecular Imaging and Nanomedicine (LOMIN), National Institute of Biomedical Imaging and Bioengineering (NIBIB), National Institutes of Health (NIH), Bethesda, MD, UNITED STATES OF AMERICA, [3]Department of Urology, Peking Union Medical College Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, CHINA, [4]Department of Pathology, Peking Union Medical College Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, CHINA.

Purpose: This study aims to document the first-in-human application of a ^{68}Ga-labeled bombesin-antagonist peptide NOTA-RM26 that targets gastrin releasing peptide receptor (GRPR). We evaluated the safety, biodistribution, calculated the radiation dose, and assessed the clinical diagnostic value in tumors. **Methods:** a macrocyclic chelator, 1,4,7-triazacyclononane-N,N',N''-triacetic acid (NOTA) conjugated GRPR antagonist RM26 was synthesized and labeled with [68]Ga. After the study protocol was approved by the institute review board, five healthy volunteers (M 3, F 2, age range 32-54 y) were enrolled to validate the safety of ^{68}Ga-NOTA-RM26. A total of 36 cancer patients including 18 prostate cancer, 11 breast cancer and 7 glioma with written informed consent were recruited. For the healthy volunteers, after low-dose CT scan, 111-148 MBq of ^{68}Ga-NOTA-RM26 was injected intravenously, followed by serial whole-body PET acquisitions. The acquisition duration was 40 sec/bed position for the 5, 10 and 15 min time points, 2 min/bed position for the 30, 45 and 60 min time points. Dosimetry was calculated using the OLINDA/EXM software. All the patients underwent ^{68}Ga-NOTA-RM26 PET/CT. GRPR immunohistochemical staining of tumor samples against GRPR was performed and correlated with PET. **Results:** The whole labeling process of ^{68}Ga-NOTA-RM26 took about 30 min with a radiochemical purity of greater than 95%. The administration of ^{68}Ga-NOTA-RM26 was well tolerated by all subjects with no adverse symptoms being noticed or reported during the whole procedure and 2 weeks follow up demonstrating the safety. A patient would be exposed to a radiation dose of 2.70 mSv with an injected dose of 129.5 MBq. For the 18 patients with pathologically confirmed prostate cancer by needle biopsy, ^{68}Ga-NOTA-RM26 PET/CT showed positive findings in 12 patients, with tracer strongly localized in primary prostate-confined lesions with SUVmax (7.20 ± 2.06), 19 metastatic lymph nodes with SUVmax (4.98 ± 2.15) and 21 bone metastasis with SUVmax (6.03 ± 4.90), respectively. Moderate to high uptake of ^{68}Ga-NOTA-RM26 were demonstrated in 11 breast cancer. The immunohistochemical staining confirmed positive correlation between the SUVs and GRPR expression level. The SUVmax and SUVmean in glioma patients at 30 min were 1.51 ± 0.28 and 2.80 ± 0.73 and tumor-to-background ratios were 29.7 ± 10.9 and 16.4 ± 7.27, respectively. **Conclusion:** This study indicates the safety and efficiency of bombesin antagonist ^{68}Ga-NOTA-RM26. This novel GRPR targeting PET radiotracer showed significant value in cancer diagnosis. ^{68}Ga-NOTA-RM26 is expected to be an excellent imaging marker to evaluate GRPR expression and guide GRPR-targeted therapy.

Schoots[1], E. de Blois[1], W. M. van Weerden[1], T. Maina[2], B. Nock[2], M. de Jong[1]; [1]Erasmus MC, Rotterdam, NETHERLANDS, [2]NCSR „Demokritos", Athens, GREECE.

Aim: Gastrin releasing peptide receptor (GRPr) targeted imaging can aid in detection of prostate cancer (PCa). However, information on tumor characteristics in correlation with clinical imaging results is still limited. Earlier we reported the potential of the diagnostic agent [68Ga]SB3 for imaging primary tumor in therapy-naive PCa patients. In this study we investigate the GRPr-expression in carcinoma lesions and normal prostate tissue in radical prostatectomy specimens. These results were correlated to [68Ga]SB3 uptake values. **Materials and Methods:** Ten therapy-naive patients with biopsy-proven PCa scheduled for curative prostatectomy were included in the study. [68Ga]SB3 (190±44 MBq, 40±5µg) was administered, followed by PET-CT imaging. PET uptake values were determined by SUV$_{max}$. Within two weeks after acquiring images, the patients underwent robot assisted radical prostatectomy. A four millimeter thick slice was immediately frozen to enable autoradiography. The remaining tissue was formalin-fixed cut into slices and paraffin-embedded. On each slice H&E staining was performed and evaluated by an expert pathologist to determine tumor localization and Gleason score (GS). In vitro autoradiography using the GRPr antagonist [111In]JMV4168 was performed on the frozen sections, GRPr expression was quantified in digital light units (DLUs). **Results:** [68Ga]SB3 PET-CT imaging visualized 13 lesions in 9 of the patients. A total of 19 tumor lesions were found in pathological evaluation of tissues of 10 patients. These lesions were classified as 9x GS6, 9x GS7 and 1x GS8. Six lesions were small, being only present in 1 slice. The frozen tissue showed tumor in 7 patients. One of these tumor lesions did not show any GRPr-expression; this was a sample from the [68Ga]SB3 PET negative patient, who showed a total of 4 lesions in pathological evaluation. The two other missed lesions were a small GS6 lesion and a GS8 lesion. GRPr-expressing tumor lesions showed significantly higher GRPr levels compared to sections with normal prostate tissue. SUV$_{max}$ uptake in tumor lesions on [68Ga]SB3 PET images showed a significant correlation to the GRPr expression levels. **Conclusion:** In this small patient group primary PCa visualization using [68Ga]SB3 PET was successful in 90% of patients. SUV$_{max}$ uptake levels showed a significant correlation with GRPr expression levels. The only [68Ga]SB3 PET negative patient had at least one GRPr negative tumor lesion.

OP-076

Imaging GRPr expression in metastatic castration resistant prostate cancer with ^{68}Ga-RM2 - A head-to-head comparison with ^{68}Ga-PSMA-11

V. Kramer[1,2], R. Fernandez[2], J. Ribbeck[1], R. Pruzzo[2], E. Hernandez-Behm[2], A. Haeger[2], B. Morales[2], H. Lavados[2], H. Amaral[1,2]; [1]Positronpharma SA, Santiago de Chile, CHILE, [2]Nuclear Medicine & PET/CT Fundación Arturo López Pérez, Santiago de Chile, CHILE.

Purpose/Introduction: Gastrin releasing peptide receptors (GRPr) are differentially overexpressed in different types of cancer including prostate cancer (PC). ^{68}Ga-RM2 is a selective PET tracer for GRPr and has shown high sensitivity for detecting primary PC and biochemical recurrent PC. ^{177}Lu-RM2 has been proposed as theranostic agent for radio ligand therapy (RLP) of advanced PC. The aim of this study is to evaluate GRPr expression in advanced metastatic castration resistant prostate cancer

(mCRPC) and to compare GRPr with PSMA expression as target for subsequent ^{177}Lu-RLT. **Subjects & methods:** We recruited 20 patients, diagnosed with mCRPC (mean age 68.0 ± 7.8 years), all with written consent and actual PSA values within one week prior to imaging (mean 496 ± 757; range 2.44-2980). All participants underwent a ^{68}Ga-PSMA-11 PET scan and a second PET scan with ^{68}Ga-RM2 within one week. Both PET studies were evaluated by overall biodistribution of the tracers and SUV_{max} and SUV_{mean} values in target lesions in prostate, soft tissue and bone. **Results:** ^{68}Ga-PSMA-11 PET was positive in all patients with mean SUV_{max} values of 34.9 ± 22.9 (range: 5.8-105.0) in target lesions. ^{68}Ga-RM2 PET was positive and able to detect GRPr expression in 18/20 patients with mean SUV_{max} values of 12.9 ± 10.8 (range: 1.4-37.8) in target lesions. ^{68}Ga-RM2 failed to detect tumor lesions in 2/20 patients and GRPr expression was significantly lower than PSMA expression in 16/20 patients. In 4/20 patients ^{68}Ga-RM2 and ^{68}Ga-PSMA showed similar distribution, SUVmax values and target expression. **Discussion/Conclusion:** GRPr expression in advanced mCRPC is significantly lower than PSMA expression and reduced in comparison to previously published data from primary and recurrent PC. Nevertheless RLT with ^{177}Lu-RM2 might be an alternative for patients with advanced mCRPC and low PSMA expression. As GRPr, and its endogen ligand GRP, show endocrine function and promote cell growth, PET imaging with ^{68}Ga-RM2 might also be a useful measure for disease prognosis.

OP-077

Imaging tumor biology with [89]Zr-cetuximab, ^{15}O-H$_2$O and ^{18}F-FDG PET/CT in patients with advanced colorectal cancer treated with cetuximab monotherapy

E. J. van Helden[1], O. S. Hoekstra[2], M. C. Huisman[2], E. Boon[3], S. C. van Es[4], G. A. M. S. van Dongen[2], D. J. Vugts[2], D. J. de Groot[4], R. Boellaard[2,5], C. M. L. van Herpen[3], E. G. E. de Vries[4], H. M. W. Verheul[1], C. W. Menke - van der Houven van Oordt[1]; [1]Department of Medical Oncology, VU University Medical Center, Cancer Center Amsterdam, Amsterdam, NETHERLANDS, [2]Department of Radiology and Nuclear Medicine, VU University Medical Center, Cancer Center Amsterdam, Amsterdam, NETHERLANDS, [3]Department of Medical Oncology, Radboud University Medical Center, Nijmegen, NETHERLANDS, [4]Department of Medical Oncology, University Medical Center Groningen, Groningen, NETHERLANDS, [5]Department of Radiology and Nuclear Medicine, University Medical Center Groningen, Groningen, NETHERLANDS.

Aim: In this multicenter study we evaluated [89]Zr-cetuximab PET/CT as predictive biomarker for treatment efficacy of cetuximab monotherapy in patients with RAS wild-type metastatic colorectal cancer (mCRC). Additionally, we evaluated if tumor perfusion on, ^{15}O-H$_2$O PET/CT, affects [89]Zr-cetuximab tumor accumulation. ^{18}F-FDG PET/CT was performed to identify (viable) tumor lesions. **Methods:** Patients with chemotherapy refractory, RAS wild-type, mCRC were treated with 500 mg/m^2 cetuximab 2-weekly (NCT02117466). Within 2 hours after the first cetuximab infusion, patients received 37 MBq [89]Zr-cetuximab (10mg) followed by PET/CT 6 days post-injection. Three independent nuclear physicians visually assessed tumor uptake. [89]Zr-cetuximab PET was classified as positive if there was visual uptake in ≥1 extra-hepatic lesion (≥2cm). In case of a negative [89]Zr-cetuximab PET, therapeutic cetuximab dose was escalated (750-1250 mg/m^2) and a second [89]Zr-cetuximab PET was performed. Tumor uptake and biodistribution were quantified and baseline blood levels of soluble EGFR (sEGFR) were measured. All patients underwent a baseline ^{18}F-FDG PET/CT and 10 patients underwent a dynamic ^{15}O-H$_2$O PET/CT. Clinical endpoints were treatment benefit (response or stable disease according to RECIST v1.1), progression-free survival (PFS) and overall survival (OS). **Results:** Twelve of 35 patients had a visually negative [89]Zr-cetuximab PET/CT. Dose escalation in eight patients did not result in visual tumor accumulation on a second [89]Zr-cetuximab PET/CT. Patients with visually positive or negative [89]Zr-cetuximab PET/CT had comparable treatment benefit (55% versus 75%, p= 0.24), PFS (median 4.4 versus 6.2 months, p= 0.35) and OS (median 9.1 versus 12.0 months, p= 0.36). In total, 129 lesions were quantified on [89]Zr-cetuximab PET/CT. SUV_{peak} of tumor lesions was comparable for patients with and without treatment benefit (2.7 versus 2.7; range 0.4-9.6). Percentage injected-dose [89]Zr-cetuximab in whole liver (potential sink organ due to high EGFR expression; median 25.3%, range 9.4-40.4%), other organs, and the blood pool (using Nadler's method, median 20.7%, range 8.9-30.5%) did not differ between patients with or without treatment benefit (p= 0.22 and p= 0.97). Tumor, blood and liver uptake were not affected by baseline plasma sEGFR concentrations. [89]Zr-cetuximab tumor uptake was positively correlated with tumor perfusion (p=0.011) on ^{15}O-H$_2$O PET/CT. Additionally, [89]Zr-cetuximab uptake was correlated with metabolic tumor activity (p<0.001), possibly due to the fact that EGFR overexpressing lesions have higher proliferation rates. **Conclusions:** [89]Zr-cetuximab PET/CT, as performed in this setting, does not predict treatment efficacy of cetuximab in patients with mCRC. [89]Zr-cetuximab uptake, perfusion and metabolic activity are positively correlated.

OP-078

A PET imaging study to investigate the biodistribution and clearance of an albumin binding domain antibody (AlbudAb™) in healthy subjects

K. Thorneloe[1], M. Bergstrom[2], L. Galinanes-Garcia[2], P. Galette[1], W. Al-Azzam[1], V. Vincent[1], D. Vugts[3], G. van Dongen[3], P. Elsinga[4], J. Wiegers[4], A. Glaudemans[4], J. Renaux[2], M. Cleveland[2], M. Davies[2], S. Zhang[1]; [1]GSK, King of Prussia, PA, UNITED STATES OF AMERICA, [2]GSK, Stevenage, UNITED KINGDOM, [3]VU University Medical Centre, Amsterdam, NETHERLANDS, [4]University Medical Center Groningen, Groningen, NETHERLANDS.

Aim: Conjugation or fusion to albumin-binding domain antibodies (AlbudAbs™) is a novel approach to extend the half-life and/or alter the distribution of biological and small molecule therapeutics. To more accurately predict and model the properties of therapeutic candidates attached to an AlbudAb in humans, we have studied the tissue distribution and elimination kinetics of unconjugated AlbudAb in healthy volunteers. **Methods**: The scaffold AlbudAb GSK3128349 was radiolabeled

with ^{89}Zirconium and a single 1 mg (~12.5 MBq) dose was intravenously administered to 8 healthy male subjects. The ^{89}Zr-GSK3128349 biodistribution was then followed for up to 7 days with 4 repeated whole body PET/CT scan sessions. PET signal intensities were measured in various organs. Blood samples were drawn at multiple time points to measure plasma PK by radio-detection and UHPLC-MS/MS analysis. **Results**: Administration of ^{89}Zr-GSK3128349 and the PET/CT procedures were well tolerated by subjects. The plasma PK profile was biexponential with a terminal half-life ($T_{1/2}$) of 18 days as measured by both radio-detection and UHPLC-MS/MS analysis. The PET images showed rapid tracer distribution primarily in the vasculature followed by gradual tissue uptake during the first 50-70 hours post dose in the kidneys, muscle and liver. SUV mean values ranged from ~9 in the kidneys and blood, to ~4 in liver and spleen, and 0.6 in skeletal muscle when averaged across all scan time points. In some organs, SUV remained constant while in other organs this decreased with time. The tissue-to-plasma ratio was in the range of 0.1-0.2 for most organs, but 0.025 for the brain suggesting limited blood-brain-barrier penetration. Muscle showed a prominent increase over time from 0.03 to 0.1 and kidney increased from 0.5 to 1.4. **Conclusions**: The ^{89}Zr-GSK3128349 biodistribution in healthy volunteers was successfully evaluated using a low level of radioactivity (~12.5 MBq). The data suggests a rapid binding of the AlbudAb to albumin with limited renal elimination, and a $T_{1/2}$ of 18 days. Similar plasma PK profiles by radio-PK and UHPLC-MS/MS suggest that the presence of ^{89}Zr did not affect the tissue distribution of the molecule. The unconjugated AlbudAb GSK3128349 biodistribution data in humans will form the base for a physiological-based PK model, which will be used to predict the biodistribution of future therapeutics linked to AlbudAbs. This information will enable the appropriate selection of targets in AlbudAb drug discovery efforts and aid in improving clinical study designs, particularly in dose selection and assessment of target engagement.

OP-079

A proof-of-concept study of ^{68}Ga-TATE-RGD PET/CT for duel-target imaging of somatostatin receptor and integrin $\alpha_v\beta_3$ to detect lung cancer and neuroendocrine tumor in a single scan

Y. Zheng[1,2], *H. Wang*[1], *X. Cui*[1], *L. Zhang*[1], *H. Tan*[2], *S. Yao*[1], *Z. Zhu*[1]; [1]*Peking Union Medical College Hospital, Beijing, CHINA,* [2]*China-Japan Friendship Hospital, Beijing, CHINA.*

Purpose: This study aims to document the first-in-human application of ^{68}Ga-TATE-RGD, a ^{68}Ga-labeled heterodimeric peptide targeting both somatostatin receptor and integrin $\alpha_v\beta_3$, in order to detect lung cancer and neuroendocrine tumors (NET) in a single PET/CT scan. **Methods:** TATE and RGD were connected with 1,4,7-triazacyclononane-N,N',N"-triacetic acid (NOTA) through 3 polyethyleneglycol (PEG$_4$) spacers (NOTA-3P$_4$-TATE-RGD). ^{68}Ga was labeled by conjugation with NOTA at 100°C for 10 min. The radiochemical purity was >99%. With IRB approval and written informed consent, 37 patients underwent ^{68}Ga-TATE-RGD PET/CT, including 18 patients with pathologically proved non-small cell lung cancer (NSCLC), 14 patients with small cell lung cancer (SCLC), and 5 patients with NET. The patients underwent PET/CT scans 40-60 min after intravenous injection of ^{68}Ga-TATE-RGD at a dosage of 1.85 MBq (0.05 mCi) per kilogram body weight. The NSCLC, SCLC and NET patients also accepted ^{68}Ga-TATE, ^{68}Ga-RGD, and ^{18}F-FDG PET/CT, respectively within 1 week for comparison. The maximum standardized uptake value (SUV) of the primary or prominent tumor (T) and the mean SUV of blood pool (B) were measured, and the T/B ratios were calculated for comparison of different tracer uptake in the same patients using the paired *t* test. **Results:** No side effect correlated with ^{68}Ga-TATE-RGD injection was found in the patients. The image quality of ^{68}Ga-TATE-RGD PET/CT was good. The kidneys and spleen showed the highest physiological uptake in the body. ^{68}Ga-TATE-RGD uptake was observed in all known lesions of NSCLC, SCLC and NET. In 18 patients with NSCLC (15 adenocarcinoma, 2 adenosquamous cell carcinoma and 1 squamous cell carcinoma), the T/B ratios of ^{68}Ga-TATE-RGD were 4.54 ± 3.00, significantly higher than those of ^{68}Ga-TATE (4.10 ± 2.83, *P*=0.0058). In 14 patients with SCLC, the T/B ratios of ^{68}Ga-TATE-RGD (6.06 ± 6.09) were significantly higher than those of ^{68}Ga-RGD (2.65 ± 1.19, *P*=0.0344). In 5 patients with NET (1 G1, 2 G2 and 1 G3 gastro-entero-pancreatic NET with multiple liver metastases and 1 thymus atypical carcinoid with multiple lymphatic metastases), the T/B ratios of ^{68}Ga-TATE-RGD were 19.79 ± 18.39, significantly higher than those of ^{18}F-FDG (2.72 ± 1.24, P=0.0187). The uptake difference was much prominent in the low grade NET. **Conclusion:** This proof-of-concept study preliminarily indicates the safety and efficacy of ^{68}Ga-TATE-RGD, a novel PET tracer targeting both somatostatin receptor and integrin $\alpha_v\beta_3$, with the possibility to detect NSCLC, SCLC, and NETs in a single PET scan using the same tracer.

Core-Satellite Nanomaterials for Multimodal Image-Guided Combination Cancer Therapy

W. Cai, S. Goel, T. E. Barnhart; University of Wisconsin-Madison, Madison, WI, UNITED STATES.

Objective: To develop a multifunctional nanoplatform integrating photothermal therapy (**PTT**) and photodynamic therapy (**PDT**) for tumor eradication under the guidance of fluorescence imaging (FL) and positron emission tomography (PET). **Methods:** Hollow mesoporous silica nanoparticles (HMSNs) were synthesized with surface -NH$_2$ groups. The hollow cavity

was loaded with Tetrakis(4-carboxyphenyl)porphyrin (TCPP, for PDT). Electrostatic adsorption was used to assemble positively-charged TCPP-loaded HMSN core ([TCPP]HMSN-NH$_2$) and negatively-charged citrate-stabilized CuS nanosatellites to form [TCPP]HMSN@nCuS core-satellite nanoconjugates (**CSNCs**), which was PEGylated. PTT (*via* CuS) and PDT (*via* TCPP) properties of CSNCs was studied by irradiation with near-infrared (NIR; 980 nm) and ultrared (660 nm) lasers respectively. CSNCs were intrinsically radiolabeled with ^{89}Zr (t$_{1/2}$=78.4 h) and serial PET and FL (*via* intrinsic FL of TCPP, ex/em: 640/720 nm) imaging were performed in 4T1 tumor-bearing mice. Combined PTT/PDT was performed in 4T1 tumors after single intratumoral injection of CSNCs, followed by laser irradiation (L$_{980}$ for 10 min and L$_{660}$ for 20 min) and tumor growth were monitored. **Results:** Transmission electron microscopy (TEM) indicated uniform morphology and excellent dispersity of the individual components as well as assembled CSNCs (~ 163 nm). High loading efficiency (~50%) of TCPP was observed, and calculations estimated ~8000 CuS nanosatellites per HMSN. CSNCs demonstrated high absorption in the ultrared and NIR windows and excellent PDT and PTT conversion efficiency upon laser irradiation *in vitro*. The oxophillic nature of ^{89}Zr and abundant -SiO$_2^-$ groups in HMSN were harnessed for chelator-free ^{89}Zr-labeling of CSNCs demonstrating excellent labeling yield (~80%) and serum radiostability. ^{89}Zr-labeled CSNCs also demonstrated Cerenkov Luminescence (CL) and Cerenkov Radiation Energy Transfer (CRET) *in vitro*. *In vivo* FL and PET showed rapid and persistent accumulation of CSNC-PEG in 4T1 tumors via enhanced permeability and retention (EPR) effect at 5.5±1.2, 5.2±1.4 and 5.0±1.0 %ID/g at 4, 24 and 48 h post-injection (p.i.). Single dose (5 mg/mL; 50 µL) of intratumorally injected CSNCs and dual-laser treatment demonstrated synergistic phototherapeutic effect in 4T1 tumor-bearing mice, with complete tumor remission and no relapse. Control groups receiving same dose of CSNCs but single-laser treatment (980nm or 660nm) showed initial tumor growth retardation up to day 7, which relapsed rapidly. Control cohorts receiving CSNC alone without laser irradiation or PBS (with and without laser irradiation) reached final relative tumor volumes of 8.1±1.6, 6.3±1.7 and 10.5±0.5, respectively, indicating negligible efficacy. **Conclusion:** A multifunctional core-satellite nanoconstruct is reported, integrating PET/FL/PDT/PTT into a single platform for image-guided synergistic cancer therapy.

OP-079c
Targeted Photodynamic Therapy in CEA Expressing Colorectal Tumor Xenografts

F. M. K. Elekonawo, D. Bos, O. C. Boerman, A. J. A. Bremers, J. H. W. de Wilt, M. Rijpkema; Radboudumc, Nijmegen, NETHERLANDS.

Introduction: Photodynamic therapy (PDT) relies on the combination of a photosensitizer and light of a specific wavelength, to create a toxic environment by formation of radical (oxygen) species. In oncology, tumor-targeted PDT might increase the efficacy of this technique by specific accumulation of the photosensitizer in tumor tissue. CEA is overexpressed in more than 90% of all colorectal cancers (CRC) and may serve as a target for

tumor-targeted PDT. Labetuzumab is a monoclonal humanized IgG with high affinity for CEACAM5, a cell surface glycoprotein that is member of the CEA family of proteins. Thus, using a labetuzumab-photosensitizer conjugate, tumor-targeted PDT for treatment of residual disease after incomplete resection of colorectal cancers might become feasible. **Purpose:** The aim of the current study is to evaluate the efficacy of tumor-targeted PDT in colorectal tumor xenografts, using labetuzumab-IRDye700DX. **Methods:** CEA-expressing cell lines LoVo, LS174T, SW1222, GW39 and HT29 were evaluated. First, cells were plated into transparent 24 well-plates and subsequently incubated with different concentrations and labetuzumab:IRDye700DX substitution ratios of 1, 2 and 4. Then, cells were washed and irradiated with different intensities (5-300 W/cm^2) of NIR light using a LED light source at 690nm. Post-therapeutic cell viability was analyzed with the ATP dependent *Celltiter Glo® Luminescent Cell Viability Assay*. Optimal labetuzumab:IRDye700DX substitution ratio and irradiation time and intensity were tested in a mouse model. Tumor growth was monitored for 8 weeks post irradiation. **Results:** All CEA-expressing cell lines were evaluated for susceptibility for tumor-targeted PDT in vitro. Post-therapeutic cell viability levels ranged from 20-90% and were dependent on the labetuzumab:IRDye700DX substitution ratio, conjugate concentration, irradiation time and intensity, and cell type. In vitro, LoVo and GW39 were more susceptible to tumor-targeted PDT than the other cell lines. The first in vivo studies are currently underway. **Discussion and Conclusion:** CEA-targeted PDT is feasible and leads to cell death in vitro. As expected, more light and higher conjugate concentrations resulted in a larger effects. Levels of CEA expression did not directly correlate with the observed effects on cell viability. This suggests that other factors, e.g. CEA availability on the cellular membrane surface and/or differences in cellular regulation of protective mechanisms could play a role in the efficacy of tumor-targeted PDT using labetuzumab-700DX. Also, an immune response to PDT is suggested to play a crucial role in the successful treatment, which is currently investigated in vivo.

OP-079d
Photodynamic therapy in rheumatoid arthritis; targeting the activated fibroblasts

D. N. Dorst[1], M. Buitinga[1], M. Brom[1], D. Bos[1], A. Freimoser[2], C. Klein[2], B. Walgreen[1], M. I. Koenders[1], M. Gotthardt[1]; [1]Radboud umc, Nijmegen, NETHERLANDS, [2]Roche Pharmaceutical Research and Early Development, Zurich, AUSTRIA.

Introduction: Rheumatoid arthritis (RA) is a chronic, inflammatory disease of the synovial joints. However, not all patients respond to conventional therapy while others lose response, warranting alternatives. Activated synovial fibroblasts, expressing the fibroblast activation protein (FAP), play an important role in developing and sustaining joint inflammation. Here, we investigated the potential of a novel FAP-targeting photodynamic therapy (PDT) to selectively induce cell death in activated fibroblasts. **Methods:** DTPA-28H1-IRDye700DX was prepared with two substitution ratios (SR) of 700DX (1.2 and 3). All *in vitro*

assays were performed with 3T3 cells, stably transfected with FAP. The immunoreactive fraction (IRF) was determined using the Lindmo assay. For PDT, cells were incubated with various concentrations of DTPA-28H1-IRDye700DX or a nonspecific antibody-700DX conjugate for 4 hours and exposed to varying LED doses. Cell viability was measured using the cell titer glo assay. For biodistribution studies, DTPA-28H1-IRdye700DX and DTPA-28H1 were labelled with ^{111}In and injected (0.4 MBq ^{111}In labelled to 50 μg Ab) in healthy C57BL/6 mice. **Results:** The IRF of [111]In-28H1-700DX (SR1.2: 94.7%, SR3: 116.8%) was comparable to that of [111]In-28H1 (91.4% (1)), indicating that conjugating 28H1 with 700DX did not affect the immunoreactivity of the antibody. To assess the effect of SR on PDT efficacy, we applied PDT to 3T3-FAP cells. 13.7 J/cm^2 LED exposure of 3T3-FAP cells incubated with 6.67 pM 28H1-700DX significantly reduced cell viability (SR1.2: 89.24%+/-3.67, SR3: 89.27%+/-2.48 compared to control (p<0.001)). No cell death was observed when cells were incubated with the control 700DX-conjugate. Conjugating the antibody to 700DX changed the *in vivo* biodistribution of the antibody, with a higher accumulation of the labelled compound in the liver (High SR :129.43 +/- 14.00 %ID/g, DTPA-only: 5.32 +/- 1.17 %ID/g (p<0.001)). Conversely, the concentration of the tracer in the blood decreased (High SR: 1.73 +/- 0.08 %ID/g , DTPA-only: 18.75 +/- 3.21 %ID/g(p<0.001)). Accumulation in the spleen, pancreas and bone marrow were also higher in the 700DX conjugated groups. **Conclusion:** We have demonstrated target-specific cell death using 28H1-700DX PDT indicating that PDT may be a promising new tool in treating RA. Conjugation of the anti-FAP antibody 28H1 with the photosensitizer 700DX did not affect the IRF. We demonstrated that higher 700DX SR resulted in faster liver clearance of the antibody. Future research will further elucidate the applicability of the conjugate for PDT in animal models of RA. **References** 1) Terry SY[1], et al. J Nucl Med. 2016 Mar;57(3):467-72.

OP-079e

Photodynamic treatment of rheumatoid arthritis by liposomal targeting of macrophages

M. Boss[1], M. Buitinga[1], D. N. Dorst[1], B. Walgreen[1], L. van Bloois[2], M. Brom[1], G. Storm[2], M. I. Koenders[1], M. Gotthardt[1]; [1]Radboud University Medical Center, Nijmegen, NETHERLANDS, [2]Utrecht University, Utrecht, NETHERLANDS.

Introduction: Rheumatoid arthritis (RA) is a chronic, progressive inflammatory disease of the synovial joints. While immunosuppressive therapy is the treatment of choice, some patients do not respond or loose response over time to this treatment. Research into alternative treatment options is therefore of importance. Resident macrophages in the arthritic joint are attractive therapeutic targets, since there is a central pathogenic role for macrophages in RA. Macrophages are numerous in the inflamed synovial membrane and at the bone-pannus junction. They contribute considerably to inflammation and joint destruction both in the acute and chronic phase of the disease. Macrophages in the arthritic joints can be targeted with liposomes, which will accumulate in these joints as a result of higher blood perfusion and vascular leakage. After accumulation in the joints, the liposomes will be phagocytosed by resident macrophages. Here we tested the feasibility of inducing cell death in macrophages by photodynamic therapy (PDT) using liposomes labelled with the photosensitizer 700DX. **Methods:** To assess the effect of PDT *in vitro*, RAW 264.7 cells were incubated for 24 hours with various concentrations of PEGylated liposomes containing 200ug/ml of the photosensitizer IRdye 700DX and control liposomes without the photosensitizer. After removing unbound liposomes, the cells were exposed to near-infrared (NIR) LED light at various intensities (ranging from 19.0 - 95.1 J/cm^2). Cell viability was assessed using a cell titer glow assay. **Results:** Incubation of the cells with concentrations of IRdye 700DX containing liposomes or control liposomes as high as 4 μg/ml did not cause cellular toxicity. After incubation with IRdye 700DX containing liposomes, NIR light exposure reduced cell viability in a dose-dependent manner. At 19.0 J/cm^2, ~50% cell viability remained. Cell viability was reduced to ~5% at 38.0 J/cm^2, while cells incubated with the control liposomes remained 100% viable at light doses as high as 95.1 J/cm^2. **Conclusion:** These data show the feasibility of introducing cell death in macrophages by photodynamic therapy with liposomal IRdye 700DX in a light-dose dependent manner. This indicates that targeting of macrophages by PDT could be a promising new method for therapy of RA. Further studies are ongoing to assess the effectiveness of this therapeutic method *in vivo* in murine models of RA.

18F-Choline PET-CT in assessment of primary hyperparathyroidism comparing with 99mTc-Sestamibi or 99mTc-Tetrofosmin SPECT-CT: How differentiate parathyroid hyperplasia from adenoma?

C. Pirich[1], L. Hehenwarter[1], L. Imamovic[2], G. Rendl[1], O. Tsybrovskyy[3], D. Hackl[4], F. Fitz[2], W. Langsteger[2], M. Beheshti[2,1]; [1]Nuclear Medicine & Endocrinology, Medical University of Salzburg, Salzburg, AUSTRIA, [2]PET-CT Center Linz, St. Vincent's Hospital, Linz, AUSTRIA, [3]Clinical Pathology, St. Vincent's Hospital, Linz, AUSTRIA, [4]General Surgery, St. Vincent's Hospital, Linz, AUSTRIA.

Aim: In this prospective study, we evaluated the accuracy of ^{18}F-Choline (FCH) PET-CT comparing with ^{99m}Tc-Sestamibi (MIBI) or ^{99m}Tc-tetrofosmin (TETRO) SPECT-CT for preoperative detection of parathyroid adenoma in patients with primary hyperparathyroidism. Furthermore, we assess the value of semi-quantitative parameters in differentiation between parathyroid hyperplasia from adenoma. **Methods:** Both FCH PET-CT and MIBI/TETRO SPECT-CT were performed in 100 consecutive patients with biochemical evidence of primary hyperparathyroidism. At least one abnormal FCH and MIBI/TETRO focus corresponding to a parathyroid gland or ectopic parathyroid tissue

in each imaging modality was considered as positive finding. In 76 patients with positive findings in at least one imaging modality, surgical exploration was performed and the results were related to histopathologic findings as the standard of truth. In 24 patients, no surgery was performed: 18 patients with positive imaging findings refused it or have been at increased general risk of surgery and 6 patients with negative imaging. **Results:** All patients showed biochemical evidence of primary hyperparathyroidism with a mean serum calcium level of 2.78 ± 0.34 mmol/l and parathormone (PTH) level of 196.5 ± 236.4 pg/ml. The results of study were analyzed in 76 patients with verified histopathology and 3 patients with negative imaging findings. Three of 6 patients with negative imaging showed normalized PTH and serum Ca levels in 3 and 6 month laboratory follow-up which was considered as "true negative". In patient-based analysis, FCH PET-CT was able to detect parathyroid adenoma in 96% of patients (76/79) while ^{99m}TC-Sestamibi SPECT-CT was positive in only 67% of patients (53/79). In a lesion-based analysis, FCH PET-CT showed a sensitivity of 93% comparing with 63% in ^{99m}TC-Sestamibi SPECT-CT. Semi-quantitative analysis by means of SUVmax showed significantly higher FCH uptake in parathyroid adenomas vs. hyperplasia [7.18 (±3.42) vs. 4.98 (±0.90); p<0.001]. Among analyzed parameters such as PTH, Ca and size and weight of parathyroid adenomas, size was significantly difference in patients with negative ^{99m}TC-Sestamibi SPECT-CT and positive FCH PET-CT [mean size (mm):17.8 ± 7.2 vs. 13.0 ± 6.7, respectively; p=0.02]. **Conclusion:** In this prospective study, FCH PET-CT showed promising results to be a potential functional imaging modality - clearly superior to MIBI or TETRO SPECT-CT - especially in the detection and localization of small parathyroid adenoma in patients with primary hyperparathyroidism. SUVmax was siginifically higher in parathyroid adenoma than in hyperplasia.

OP-081

Quantitative Washout Rate of ^{99m}Tc-Sestamibi in Parathyroid and Thyroid Tissues Assessed Using Quantitative SPECT-CT

J. Gardner, B. Ziebarth, S. Bazarjani, S. Razavi, R. Klein, L. S. Zuckier, W. Zeng; The Ottawa Hospital, Ottawa, ON, CANADA.

Introduction: Dual phase parathyroid scintigraphy is a well-established procedure for preoperative localization of parathyroid adenomas. Although discrimination of parathyroid adenomas has been postulated as occurring due to more-rapid washout of ^{99m}Tc-Sestamibi (MIBI) from thyroid than from parathyroid adenomas, there are limited quantitative data reported in the literature to support this hypothesis. In our center, in addition to planar images, we obtain early SPECT-CT and 2-hour delayed SPECT imaging for anatomic localization. The aim of this study was to employ quantitative methods to derive tissue MIBI washout rates from our SPECT data. **Materials and Methods :** We retrospectively studied 125 consecutive patients (age: 62.2±13.8, F:M=100:25) accrued over 10 months. Lab values (mean±SD) were tabulated for PTH (28.5±54.1 pmol/L), calcium (2.60±0.45 mmol/L), TSH (2.61±2.20 mIU/L), T4 (12.18±2.52 pmol/L) and T3

(4.54±0.74 pmol/L). Early CT scans were co-registered with delayed SPECT using a previously validated manual method. Early and late SPECT-CT images were reconstructed using attenuation, scatter, and resolution recovery correction and quantified in Standard Uptake Value (SUV) units (HERMES HybridRecon). Maximum SUV (SUV$_{max}$) were measured on all image sets. Thyroid lobes were considered measurable if they are found clearly separated from parathyroid adenoma and if patients were not receiving exogenous thyroid hormone. Washout rates for normal thyroid tissue and parathyroid adenomas were calculated using early and late SUV$_{max}$. **Results:** Of the 125 patients imaged, 59 adenomas were successfully localized in 58 patients (1 patient with 2 adenomas) and these patients were subject to analysis below. There was an overall significant difference in PTH levels between the patients with and without localizable parathyroid adenomas (47.5± 90.2 pmol/L vs. 18.6± 19.3 pmol/L, p=0.03). SUV$_{max}$ was higher in parathyroid adenomas than in measurable thyroid lobes on both early (7.23 ± 4.59 vs. 4.56 ± 1.43, p<0.001) and late (4.46 ± 3.53 vs. 2.02 ± 0.77, p<0.001) images. Mean washout rates (%/hour) from parathyroid adenomas was slower than that of the thyroid lobes in patients positive for parathyroid adenoma (21.8% ± 9.6% vs. 32.1% ± 11.2%, p<0.001). **Conclusion:** Quantitative SPECT-CT analysis revealed higher absolute SUV values in parathyroid adenomas versus thyroid tissue, as well as a statistically higher rate of MIBI washout from the thyroid tissue. Our data therefore support the hypothesis that discrimination of parathyroid adenomas on dual-phase studies occurs, at least in part, due to the more-rapid washout of ^{99m}Tc-Sestamibi (MIBI) from thyroid than from parathyroid tissue.

OP-082

A Type of Uptake in Dual-phase ^{99m} Tc-Sestamibi SPECT/CT Parathyroid Scintigraphy & a Level of Parathormone Might Indicate a Histopathology Diagnosis in Patients with Primary Hyperparathyroidism-Experience of One Centre

M. H. Listewnik, H. Piwowarska-Bilska, K. Safranow, M. Ostrowski, J. Iwanowski, M. Chosia, A. Borowiecki, M. Laszczyńska, M. Kurnatowicz, B. Birkenfeld; Pomeranian Medical University in Szczecin, Szczecin, POLAND.

Introduction/purpose: This prospectively designed study aimed to assess the concordance between abnormal results of preoperative dual-phase ^{99m}Tc-Sestamibi SPECT/CT parathyroid scintigraphy, histopathology (HP), biochemical parameters in patients operated on for primary hyperparathyroidism (pHPT). **Subject & Methods:** In 181 among 242 patients with suspicion of pPHP abnormal result were found. Three types of ^{99m}Tc-Sestamibi uptake: I-lack in an early (thyroid) phase (EP) and presence in a delayed (parathyroid) phase (DP); II-presence in EP and DP;III-presence in EP and lack in DP were distinguished. Patients with more than one lesion were excluded to obtain the subgroup "one lesion and one parathormone (PTH) result" (n=137). Among 181 patients with abnormal result, 40 (mean age 58.7 years) patients had surgery. In surgery group 45 from 46 lesions indicated on ^{99m}Tc-SestamibiSPECT/CT basis were removed and

sent for HP. According to the rule "one lesion and one PTH result" 37 from 45 removed lesions were further analyzed PTH was analyzed in relation to three types of[99m]Tc-Sestamibi uptake. Additionally, in the surgery group HP was examined in relation to PTH in types of ^{99m}Tc-Sestamibi uptake. **Results:** Type I of uptake presented 18.3% (n=25) lesions, type II 70.8% (n=97) and type III 10.9% (n=15). A significant difference between PTH plasma concentration in relation to three types of tracer uptake was found (p=0.002). PTH level in type II was significantly higher than in type I and III (p=0.002 and 0.023, respectively). In the surgery group 37 (80.4%) lesions in EP and 44 (95.6%) in DP showed abnormal uptake in ^{99m}Tc-SestamibiSPECT/CT. On the basis of HP results as true positive were established: parathyroid adenoma (n=20; 44.5%), parathyroid hyperplasia (n=11; 24.5%), parathyroid cancer (n=2; 4.4%) and normal parathyroid gland (n=4; 8.9%). As false positive: lymph nodes (n=2; 4.4%) and thyroid gland (n=6; 13.3%). Positive predictive value of the method was 82.2%. In the surgery group PTH was significantly higher for type II of uptake than for type I (p=0.039). In patients with type II uptake, PTH concentration was significantly higher in adenoma than in hyperplasia subgroup (p=0.01). **Discussion/Conclusion:** (1) In SPECT/CT parathyroid scintigraphy ^{99m}Tc-Sestamibi uptake is generally visible both in thyroid and parathyroid phase (2) In patients with type II of uptake higher PTH concentration might distinguish parathyroid adenoma from parathyroid hyperplasia. This study was supported by a grant from budget resources for science in the years 2010-2015 as research project No. N N402 463339.

Comparison of F-18 Choline PET/CT with Tc-99m MIBI and USG for Detection of Parathyroid Adenomas in Patients with Elevated Parathyroid Hormone Levels: Preliminary Results

L. Uslu-Beşli[1], K. Sönmezoğlu[1], E. Kaymak Akgün[1], S. Teksöz[2], E. Karayel[1], H. Pehlivanoğlu[1], M. Ocak[3], T. Öztürk[4], S. Sağer[1], L. Kabasakal[1], Y. Bükey[2]; [1]Istanbul University Cerrahpaşa Medical Faculty Department of Nuclear Medicine, Istanbul, TURKEY, [2]Istanbul University Cerrahpaşa Medical Faculty Department of General Surgery, Istanbul, TURKEY, [3]Istanbul University Pharmacy Faculty Department of Pharmaceutical Technology, Istanbul, TURKEY, [4]Istanbul University Cerrahpaşa Medical Faculty Department of Pathology, Istanbul, TURKEY.

Purpose: In patients with elevated parathyroid hormone(PTH) levels, conventional imaging modalities including ultrasonography(USG) and parathyroid scintigraphy with Tc-99m MIBI(MIBI) are used for detection of suspected parathyroid adenomas. However, both modalities could be negative despite persistent hyperparathyroidism. F-18 Choline(FCH) PET has recently been suggested to be a better alternative for detection of parathyroid adenomas. The aim of our study is to compare the diagnostic accuracy of FCH-PET with conventional imaging modalities for detection of parathyroid adenomas. **Subjects and Methods:** Among 130 adult patients with primary or secondary hyperparathyroidism that have been prospectively enrolled in our

on-going study, 93 patients with postoperative histopathological confirmation or follow-up biochemical results were included in our comparison. FCH-PET/CT, MIBI dual-phase imaging and USG were performed to all patients. Mean 8,8±2,4 mCi(325±88,8 MBq) FCH was applied iv and dual-time PET/CT imaging was performed 15min and 45min after FCH administration. Gold standard was postoperative histopathology in patients that have undergone parathyroidectomy operation, and follow-up serum PTH, calcium, phosphate and vitamin-D levels in patients with negative imaging results. **Results:** Total 61 patients underwent surgery, resulting in parathyroid adenoma in 54, neoplasia in 3 and hyperplasia in 3 patients. In one patient parathyroid tissue was not found in the pathology specimen. FCH-PET could successfully localize 95,1% of the hyperfunctioning parathyroid glands among operated patients. It was false negative(FN) in 3,3% and false positive(FP) in 1,6% of patients. Sensitivity and positive predictive value(PPV) of FCH-PET are 96,7% and 98,3%, respectively. MIBI could detect only 48,3% of the lesions and missed 50%. USG was positive in 50% of the lesions and missed 48,1%. Sensitivity of MIBI and USG remained 49,2% and 51,0%, respectively. Total 32 patients were followed without surgery and PTH levels decreased in 9 patients, remaining high in 23 patients. FCH was positive in 52,2%(12/23) of patients with persistent hyperparathyroidemia, whereas MIBI and USG was positive in 17,4%(4/23) and 8,7%(2/23), respectively. Out of 30 patients, that were negative with both MIBI and USG, 15 were FCH positive and adenoma was confirmed with histopathology in 10 patients, whereas PTH level remained high in 5 patients, who could not be operated. **Conclusion:** FCH-PET is an effective imaging tool with higher sensitivity compared to conventional imaging modalities for detection of hyperfunctioning parathyroid glands. It should be used especially in cases with persistent hyperparathyroidism despite negative MIBI and USG results. OP-084

Impact of F18-Fluorocholine PET/CT in the pre-surgical work up of primary hyperparathyroidism

S. Grimaldi[1], J. Young[2], P. Kamenicky[2], D. Hartl[1], M. Terroir[1], S. Leboulleux[1], E. Baudin[1], M. Schlumberger[1], D. Deandreis[1,3]; [1]Institut Gustave Roussy, Villejuif, FRANCE, [2]Hôpital de Bicêtre, Le Kremlin-Bicêtre, FRANCE, [3]Università degli Studi, Torino, ITALY.

Introduction: Pre-surgical localization of hyper-functioning parathyroid gland in patients with primary hyperparathyroidism (HPT) is crucial, but it can be difficult in case of multi-glandular disease, small adenomas, and relapse after previous surgery. Due to promising results in previous studies, the aim of our study was to evaluate the added value to standard work up of F18-Fluorocholine (FCH) PET/CT in this pre-surgical setting. **Patients and Methods:** We evaluated 27 consecutive patients with primary HPT that underwent Tc99mMIBI scintigraphy, neck US and FCH PET/CT (median age 58 years; 19 F, 8 M). FCH PET/CT was added to standard work up in patients with (i) non-conclusive/ negative pre-surgical localization with MIBI scintigraphy and US

(n=20); (ii) relapse of previously surgically treated primary HPT or clinical suspicion of multiple gland disease for HPT familiar forms (n=7). Sensitivity (Se), specificity (Sp), positive predictive value (PPV) and negative predictive value (NPV) of FCH PET/CT were calculated in a per gland analysis. Histological findings and postoperative biochemical resolution of HPT were considered as the gold standard. **Results:** FCH PET/CT was positive in 24/27 patients. Finally 21/27 patients underwent surgery with a total of 27 resected lesions. Despite a positive FCH PET/CT six patients did not undergo surgery because of comorbidities, refusal and/or stable calcium level. Nineteen/21 patients (90%) had a biochemical resolution of HPT after surgery. Histological examination of 27 resected lesions found adenomas (n=14), hyperplastic glands (n=11) and hyper-functioning glands with normal histological appearance (n=2). In two patients HPT persisted after surgery and at least one lesion was localized neither at imaging nor at the surgical exploration. FCH PET/CT successfully localized 22/29 hyper-functioning glands (per gland Se 76%; PPV 85%, Sp 93%; NPV 88%). FCH PET/CT correctly identified 13/17 lesions in patients with a single lesion (Se 76%, PPV 76%, Sp 92%; NPV 92%) and 9/12 hyper-functioning glands in patients with multiple gland disease (Se 75%, PPV 100%, Sp 100%; NPV 57%). In particular in patients with previous neck surgery FCH PET/CT was able to localize all sites of recurrence (10/10 lesions). **Conclusion:** FCH PET/CT is a promising imaging modality in the pre-surgical localization of hyper-functioning parathyroid glands especially as a second line examination in patients with non-conclusive pre-surgical localization with MIBI scintigraphy and neck US and/or an additional method in those patients in which standard work up performance is known to be limited (in particular in case of disease relapse).

OP-085

Factors Associated with the Occurrence of Graves' Orbitopathy after Radioiodine Therapy in Patients with Graves' disease

S. Gaberscek[1,2], D. Šfiligoj[1], K. Zaletel[1], E. Pirnat[1], P. Jaki Mekjavić[3,2];
[1]Department of Nuclear Medicine, University Medical Centre Ljubljana, Ljubljana, SLOVENIA, [2]Faculty of Medicine, University of Ljubljana, Ljubljana, SLOVENIA, [3]University Eye Hospital, University Medical Centre Ljubljana, Ljubljana, SLOVENIA.

Purpose: In patients with Graves' disease (GD) Graves' orbitopathy (GO) may occur or worsen after therapy with radioactive iodine 131 (RAI). Several factors have been proposed to be associated with the worsening of GO after RAI. The aim of our study was to retrospectively establish factors associated with the occurrence of GO after RAI in patients without GO immediately before RAI. **Subjects and Methods:** In this retrospective study we reviewed medical records of all patients who were first diagnosed with GD between January 2005 and December 2009 and later treated with RAI. Out of 724 patients, 552 patients (427 women and 125 men) did not have GO immediately before RAI. The state of GO was followed for 12 months after RAI therapy. We evaluated the role of sex, age, smoking, duration of treatment with antithyroid drugs, level of TSH receptor antibodies before RAI, presence of GO at the first examination of GD, and number of doses of RAI. **Results:** Out of 552 patients, 529 patients (407 women and 122 men) remained without GO after RAI, while in 23 patients (20 women, 3 men), GO occurred after RAI. Between the two groups we found no difference with respect to sex (p=0.261). Patients without GO after RAI did not differ from patients with GO after RAI with respect to age (median, 46 and 43 years, respectively, p=0.113). We found no statistically significant differences between patients without GO after RAI and patients with the occurrence of GO after RAI with respect to smoking, duration of treatment with antithyroid drugs, and level of TSH receptor antibodies (p=0.380, p=0.379, p=0.875, respectively). Patients with the occurrence of GO after RAI had significantly more frequently GO at the first examination than patients without GO after RAI (13% and 3.8%, respectively, p=0.030). The first dose of RAI was effective in 504 (91.3%) GD patients, while the second and the third dose of RAI were required in 48 (8.7%) and 3 (0.5%) patients respectively. In patients treated with the second and third dose of RAI, GO occurred significantly more frequently than in patients treated with a single dose of RAI (p=0.008 and p<0.001, respectively). **Conclusion:** Patients with GO at presentation of GD have a higher risk of developing GO after RAI. Our results reveal the importance of a sufficiently high first dose of RAI since additional doses of RAI increase the likelihood of the occurrence of GO.

OP-086

Factors Associated with the Duration of Graves' Orbitopathy Activity in Patients with Graves' disease

S. Gaberscek[1,2], D. Šfiligoj[1], K. Zaletel[1], E. Pirnat[1], P. Jaki Mekjavič[3,2];
[1]Department of Nuclear Medicine, University Medical Centre Ljubljana, Ljubljana, SLOVENIA, [2]Faculty of Medicine, University of Ljubljana, Ljubljana, SLOVENIA, [3]University Eye Hospital, University Medical Centre Ljubljana, Ljubljana, SLOVENIA.

Objective: Radioiodine (RAI) is a safe and effective definitive treatment of Graves' disease (GD). However, in patients with concomitant active Graves' orbitopathy (GO), special caution is usually recommended. Glucocorticoids are used to prevent worsening of GO after RAI. The duration of GO activity in patients treated with RAI is not precisely established. Our aim was to evaluate factors associated with the duration of GO activity. **Subjects and Methods:** In this retrospective study we reviewed medical records of all patients who were first diagnosed with GD between January 2005 and December 2009 and later treated with RAI. Out of 724 patients, 154 patients had mild or moderate-to-severe active GO. Immediately after RAI, all but two patients received glucocorticoids in various regimens. The course of GO was followed until GO became inactive. We evaluated the role of age, duration of treatment with antithyroid drugs, and the role of the timespan until RAI. **Results:** The median age of 124 women and 30 men with the active GO was 45 years (range, 16-75 years). The median duration of GO activity was 8 months (range, 2-24 months). The median duration of the treatment with antithyroid drugs was 7 months (range, 0-22 months). We found no significant correla-

tion between the age, the duration of treatment with antithyroid drugs and the duration of GO activity (R=0.087, p=0.283; R=0.019, p=0.817, respectively). The median timespan until RAI was 7 months (range, 1-48 months). The duration of GD activity was significantly shorter in patients who received RAI therapy up to 6 months after GD occurrence than in patients who received RAI later (median, 7 and 10 months, respectively, p=0.032). We found a significantly positive correlation between the timespan until RAI and the duration of GO activity (R=0.206, p=0.010). Furthermore, with multiple regression analysis, the timespan until RAI was significantly associated with the duration of GO activity (beta=0.198, p=0.014), while age and duration of treatment with antithyroid drugs did not show such association (beta=0.016, p=0.847; beta=0.041, p=0.624, respectively). **Conclusions:** Our results reveal the beneficial effect of the timely RAI therapy on the course of GO, since the shorter the time until RAI therapy the shorter the duration of GO activity. It seems that in patients with active GO "the sooner the better" principle as regards RAI therapy should be considered.

Background and Aim: We already reported activity and safety of 177Lu-dotatate (Lu-PRRT) at different dosages in patients with metastatic progressive GI-NETs. A minimal effective PRRT activity was determined and prognostic factors such as the presence of FDG avid lesions was addressed. Here we report the five year follow up (FU) and the role of hepatic involvement in advanced GI NET patients treated with of Lu-PRRT. **Patients and Method:** The study was prospective, phase II, open label and disease-oriented. Every 6 to 8 weeks, all patients received 3.7 GBq or 5.5 GBq of 177Lu-DOTATATE each cycles repeated 5 times (Total Activity 18.5 GBq or 27.5 GBq according to the presence of toxicity risks). **Results:** 43 patients (28M and 15 F) were evaluable and were monitored for a median period of 67 months (range 12.6-96.3). All patients had PET 68Ga-dotapeptide/octreoscan positive in documented lesions. Median PFS of patients who received reduced activity (RA) was 55.6 mo (29.8-69.0) while median PFS of patients treated with full activity (FA) was 52.7 mo (23.3-69.0; p=0.999). Median OS was 82.0 mo (55.6-nr, p=0.4) in patients who received FA and has not been reached in those treated with RA. FDG PET imaging was available in 33/43 patients (77 %). When no FDG uptake was present at tumor site median PFS was 60.1 mo (36.8-nr), while PFS was 29.8 mo in FDG positive patients (9.0-69.0, p=0.05). In 19 patients (44.2%) with less than 6 liver metastases, PFS was 55.6 mo (18.0-nr), while in 18 pts (41.9%) with more than 6 hepatic lesions was 30.4 mo (14.3-36.8, p=0.01). Neither hematological nor renal grade 3-4 toxicity was noticed in both groups. **Conclusion:** After 5 years of FU, Lu-PRRT proves to be a safe and effective therapeutic option in advanced GI NET. Important prognostic factors are the presence of FDG avid lesions and hepatic involvement regardless total activity injected.

OP-100

Update: Edmonton Lu-177 Protocol (Induction and Maintenance Regimen) Improves Progression Free Survival (PFS) in Patients with Advanced Neuroendocrine Tumours (NETs)

A. J. B. McEwan[1], M. Wieler[1], D. Murray[1], M. B. Sawyer[1], D. Morrish[1], B. A. Schaitel[2], L. D. Schrader[2], T. McMullen[1]; [1]University of Alberta, Edmonton, AB, CANADA, [2]Cross Cancer Institute, Alberta Health Services, Edmonton, AB, CANADA.

Introduction: The Edmonton LuTATE Protocol (ELP) - a PRRT protocol of induction (4 cycles of up to 6.11 GBq every 10 - 14 weeks) and long-term maintenance treatment (up to 8 cycles of up to 4.07 GBq /cycle every 5.5 - 10 months) - is an effective therapeutic option for patients with advanced gastrointestinal and pancreatic NETs (GEPNETs). We hypothesize ELP improves outcomes, and is effective and safe for these patients. We evaluated toxicity and PFS in a GEPNET cohort in a 2nd interim analysis of ELP. **Subjects & Methods:** A subset of 170 participants of the 195 enrolled in the Edmonton LuTATE Protocol had PNETs (n=49), GNETs (n= 103), or presumptive GNETs (n=18). Of these 170 participants, 22 had 1-2 cycles, 42 had 3-4 cycles, 40 had 5-6 cycles, 29 had 7-8 cycles, 26 had 9-10 and 11 had 11-12 cycles. Cumulative mean administered dose was 6.53 ± 2.52 GBq (1-2 cycles), 17.03 ± 2.84 GBq (3-4 cycles), 23.96 ± 4.40 (5-6 cycles), 30.18 ± 4.47 GBq (7-8 cycles), 38.38 ± 4.05 GBq (9-10 cycles) and 48.92 ± 5.77 GBq (11-12 cycles). Doses were modified by a defined algorithm for age, metastatic burden and renal function. **Results:** 124 patients remain on treatment and 46 have stopped treatment: 1 is surgically confirmed disease free (after 4 cycles); 3 have no clinical evidence of disease; 24 have discontinued due to biochemical, anatomic or symptomatic progression between cycles (after 1-2 cycles, n=5; after 3-4, n=3, after 5-6; n=3, after 7-8; n=5, after 9-10; n=6, after 11-12, n=2); and 18 died (after 1-2 cycles, n=6; after 3-4, n=2, after 5-6; n=5, after 7-8; n=3, after 9-10; n=2). Mean time from first treatment: 11.0 weeks -1-2 cycles; 31.8 weeks - 3-4 cycles; 18.6 months - 5-6 cycles; 7-8 cycles - 30.8 months; 47.4 months - 9-10 cycles; and 62.5 months - 11-12 cycles. A Kaplan-Meier survival curve shows median PFS is ~55.7 months. Transient Grade 2 renal toxicity was seen in 16% of patients; transient Grade 3 haematological toxicity was seen in 15% of patients; no Grade 4 toxicity was observed. **Conclusion:** These data support our hypothesis that Edmonton LuTATE Protocol improves PFS in patients with GEPNETS, and supports the hypothesis of low dose hypersensitivity as the mechanism of action for PRRT in GEPNETS. This regimen is more effective than literature reported treatment regimens; in this cohort, median PFS is ~55.7 months

OP-101

Improvement of PFS and OS after salvage therapy with 177-Lu[Dota0,Tyr3]octreotate in patients with gastroenteropancreatic and bronchial neuroendocrine tumours - the Rotterdam cohort

W. A. van der Zwan[1], T. Brabander[1], B. L. K. Kam[1], J. J. M. Teunissen[1], E. P. Krenning[2], D. J. K. Kwekkeboom[1], W. W. de Herder[1]; [1]Erasmus

MC, Rotterdam, NETHERLANDS, ²Cyclotron BV, Rotterdam, NETHERLANDS.

Aim: Peptide receptor radionuclide therapy (PRRT) with 177-Lu[Dota⁰,Tyr³]octreotate is an effective treatment option for patients with metastasized and/or inoperable neuroendocrine tumours. We evaluated the efficacy and toxicity of salvage therapy with PRRT in a large group of patients with a long follow-up. **Materials and Methods:** Dutch patients with gastroenteropancreatic or bronchial neuroendocrine tumours were selected for re-(re)-treatment if they had had benefit from initial therapy and suffered from renewed progressive disease. Benefit is defined as objective response of at least a partial response according RECIST 1.1 or conversion of progressive disease into stable disease. The cohort underwent salvage therapy between October 2003 and October 2015, with follow-up up to and including December 2016. The intended cumulative dose for re-(re)-treatment was 14.8 GBq (400mCi) divided over two administrations. The total intended cumulative dose per patient for the initial treatment was 29.6 GBq (800mCi), for re-treatment 44.4 GBq (1200mCi) and for re-re-treatment 59.2 GBq (1600mCi). **Results:** In our study a total of 181 patients were re-treated and 14 patients were re-re-treated. Median follow-up was 91 months. Patients were re-treated with a median cumulative dose of 14.9 GBq (range 3.7-16.2 GBq)/400mCi (range 100-400mCi) and re-re-treated with a median cumulative dose of 15.0 GBq (range 3.8-15.3GBq)/400mCi (range 100-400mCi). After initial therapy the median PFS and OS were 33 (**95% CI [30.4, 35.6])** and 77 (**95% CI [63.1, 91.0])** months, respectively. Median PFS after re-treatment was 14 (**95% CI [11.7, 16.3])** months and OS was 26 (**95% CI [18.9, 33.1]**) months. Median PSF and OS after re-re-treatment was 14 (**95% CI [9.8, 18.2])** months and 29 (**95% CI [4.6, 53.4])** months. Severe long-term haematological toxicity includes 2 cases of acute myeloid leukemia and 1 myelodysplastic syndrome, a total of 1.7%. No Grade III or Grade IV nephrotoxicity with regard to PRRT was seen. **Conclusion:** Salvage therapy with 177-Lu[Dota⁰,Tyr³]octreotate is a feasible treatment option in patients with a good response after initial therapy. The occurrence of severe haematological toxicity is not higher then previously reported.

OP-102

Investigation of Receptor Radionuclide Therapy with 177Lu dotatate in GEP-NEN patients with High Grade Ki67

S. Nicolini¹, S. Severi¹, M. Sansovini¹, A. Ianniello¹, P. Caroli¹, A. Bongiovanni², A. Rossi³, F. Di Mauro⁴, E. Mezzenga⁵, E. Scarpi⁶, G. Paganelli¹; ¹Nuclear Medicine and Radiometabolic Unit, Istituto Scientifico Romagnolo per lo Studio e la Cura dei Tumori (IRST) IRCCS, Meldola (FC), ITALY, ²Osteoncology and Rare Tumors Center, Istituto Scientifico Romagnolo per lo Studio e la Cura dei Tumori (IRST) IRCCS, Meldola (FC), ITALY, ³Radiology Unit, Istituto Scientifico Romagnolo per lo Studio e la Cura dei Tumori (IRST) IRCCS, Meldola (FC), ITALY, ⁴Nuclear Medicine Unit, University of Messina, Messina, Italy, Messina, ITALY, ⁵Medical Physics Unit, Istituto Scientifico Romagnolo per lo Studio e la Cura dei Tumori (IRST) IRCCS, Meldola (FC), ITALY, ⁶Unit of Biostatistics and Clinical Trials, Istituto Scientifico Romagnolo per lo Studio e la Cura dei Tumori (IRST) IRCCS, Meldola (FC), ITALY.

Background and Purpose: The WHO 2010 classification divides gastroenteropancreatic neuroendocrine neoplasia (GEP-NEN) in 3 categories based on ki67 proliferation index: NET G1: ki67<3%; NET G2: ki67 3-20%; NEC G3: ki67>20%. Accordingly, a cut-off of ki67>20% distinguishes high-grade GEP-NEC from intermediate grade; however, in clinical practice a ki67>15% is considered as a high-grade and often treated with standard schemes of chemotherapy. There is evidence that some high-grade NENs have a moderate aggressive behavior and can express somatostatin receptors (in 40-70% of cases) allowing the possibility of a targeted therapy. PRRT is one of the most important targeted therapy in the management of NET and several studies have demonstrated its efficacy in G1-G2 GEP-NETs. The aim of this study was to investigate the role of PRRT with 177Lu-DOTATATE (Lu-PRRT) in GEP-NENs with a ki67 index ranging from 15% to 70%. **Methods:** 33 patients affected by GEP-NEN with ki67 from 15% to 70% were treated with Lu-PRRT. All patients, with positive somatostatin receptor imaging (SRI+), had advanced disease and had been already treated with standard therapies. A cumulative activity of 18.5GBq or 27.8 GBq in 4 to 5 cycles was administered according to kidney and bone marrow reserve. Receiver operating characteristic (ROC) curve was used to determine the best threshold of ki67 expression to predict PD (progression disease). **Results:** The median follow-up was 43 months (range 3-69). Overall response was PR in 2 patient (6 %) and SD in 21 (64%), with a DCR of 70%. Median PFS was 23 months (95 % CI 14.9-31.0 months) and median OS 52.9 months (95 % CI 17.1-68.9 months). ROC curve analysis at 23 months revealed that the best cutoff value of ki67 expression was 35%. 24 patients had ki67≤35% and 10 patients had ki67 ranging 36-70%. Analyzing outcome according to proliferation index, in the group with ki67 ranging 15%-35% the DCR was 87% whereas in the group with ki67 >35%, DCR was 30%. The mPFS was 26.3 months (95 % CI 18.4-37.7 months) in the first group while was 6.8 months (95 % CI 2.1-27 months) in the second group (p=0.005). **Conclusion:** Lu-PRRT showed antitumor activity in advanced SRI+ high-grade GEP-NENs. DCR and PFS were significantly better in GEP-NEN patients with ki67 ≤35% compared to patients with ki67>35%. Accordingly to our experience, PRRT should be considered as a therapeutic option in patients affected by intermediate-high grade, SRI+, GEP-NEN, in particular with ki67≤35%.

OP-103

177Lu-Dotatate Peptide Receptor Radionuclide Therapy Dose Response in Small Intestinal Neuroendocrine Tumors

U. M. M. Jahn¹, E. Ilan¹, M. Sandström¹, M. Bamerny², U. Garske-Román³, M. Lubberink², A. Sundin¹; ¹Radiology, Uppsala, SWEDEN, ²Nuclear Medicine, Uppsala, SWEDEN, ³Nuclear Medicine, Gothenburg, SWEDEN.

Aim: To estimate the relationship between the absorbed tumour dose during ¹⁷⁷Lu-DOTATATE-therapy and subsequent

tumour shrinkage in small-intestinal neuroendocrine tumour (SI-NET) metastases. **Methods:** Between November 2005 and October 2014, 108 consecutive patients with inoperable and progressive SI-NETs were treated with dosimetry guided ^{177}Lu-DOTA-octreotate peptide receptor radionuclide therapy (PRRT), undergoing SPECT/CT during each therapy cycle. Thirty-one patients with at least one well-circumscribed tumour lesion on SPECT/CT were selected and analysed by extended dosimetry during the treatment administered as 3-7 cycles of 7,4 GBq ^{177}Lu-DOTA-octreotate at 6-8-weeks interval. The absorbed tumour dose was calculated from activity measurements on sequential SPECT/CT at 24, 96 and 168 h post infusion applying the unit density sphere model from OLINDA. The partial volume effects in the SPECT measurements were corrected, based on phantom measurements. The morphological response on tumour diameter, tumour volume, liver tumour volume and liver volume as well as RECIST 1.1 was evaluated by CT/MRI. Results: The absorbed tumour dose from baseline to best response (BRTR)(% tumour diameter reduction) ranged 38 to 408 Gy. The total administered activity during PRRT correlated to tumour diameter shrinkage (R^2=20% P=0,02). The mean specific activity of the 177Lu-octreotate preparations correlated to the absorbed tumour dose (R= 32%, P=0,001). No correlation was found between the absorbed tumour dose and tumour shrinkage. No correlations were found between the liver tumour volume and the liver volume or the absorbed dose and the total administered activity. The median follow up time from the start of PRRT was 17 months (range 7 to 50 months). When applying RECIST 1.1 criteria, the median time from start of PRRT to best response was 15 months. 5/26 patients developed progressive disease at 28, 29, 29, 34 and 41 months, respectively. 3/26 patients demonstrated partial response and 18/26 patients had stable disease at the latest follow up. **Conclusion:** SI-NET shrinkage correlated to the total administered ^{177}Lu-activity. The method used for calculating the absorbed dose in SI-NET tumours failed to demonstrate an absorbed tumour dose-response relationship in the chosen SI-NETs. The mean specific activity of the preparations correlated to the absorbed tumour dose. The specific activity may be an important factor and its impact needs to be considered in future research on PRRT.

OP-104

Gender-related differences in absorbed dose to risk organs in patients receiving ^{177}Lu-Octreotate therapy

M. Sandstrom, Sr.[1,2], *E. Ilan*[1,2], *K. Fröss-Baron*[1], *U. Garske-Roman*[1], *D. Granberg*[3], *B. Eriksson*[3], *A. Sundin*[1], *M. Lubberink*[1,2]; [1]*Nuclear medicine and PET, Uppsala University, Uppsala, SWEDEN,* [2]*Medical physics, Uppsala University Hospital, Uppsala, SWEDEN,* [3]*Endocrine Oncology, Uppsala University, Uppsala, SWEDEN.*

Aim: Fractionated therapy with ^{177}Lu-octreotate is an effective treatment option for patients with generalized neuroendocrine tumors. The aim of the present work was to study gender-related differences in absorbed dose to risk organs and if weight, length or lean body mass could explain gender differences for the absorbed doses to risk organs in patients receiving therapy with ^{177}Lu-octreotate. **Methods:** Five hundred patients (250 female and 250 male) with neuroendocrine tumors with high somatostatin receptor expression were included. SPECT/CT images were acquired at 24, 96 and 168 h after infusion of 7.4 GBq of ^{177}Lu-octreotate and absorbed doses to kidneys and liver were calculated using previously described methods. Absorbed doses in men and women were compared using Mann-Whitney tests. The relation between absorbed dose and gender and either body weight, length, lean body mass, or both body weight and length was assessed using multiple regression. P-values less than 0.05 were treated as significant and P-values less than 0.001 were treated as highly significant. **Results and discussion:** Absorbed doses to left and right kidneys were 4.9 and 4.6 Gy for women and 3.9 and 3.8 Gy for men, respectively ($p < 0.0001$). Absorbed doses to liver were 2.1 Gy in both men and women (n.s.). For both kidneys, absorbed dose was highly correlated to gender ($p < 0.0001$) regardless of other independent variables, but partial correlation to body weight was significant as well: p 0.013 using only gender and weight as independent variables and $p < 0.01$ when using gender, weight and length as independent variables. Partial correlations with length and lean body mass were not significant. For liver, absorbed dose was correlated primarily to body weight ($p < 0.05$), whereas partial correlations to gender, length and lean body mass were non-significant. **Conclusions:** There is a significant difference between absorbed doses to the kidneys in men and women receiving ^{177}Lu-octreotate therapy, with a much higher partial correlation to gender than to body weight. No significant differences in absorbed doses to liver between men and women were found, with liver absorbed doses correlating only to body weight. Since kidney is the dose-limiting organ in ^{177}Lu-octreotate therapy, this gender difference in absorbed doses should be taken into account in treatment planning.

OP-105

177Lu-DOTATATE therapy in radio iodine refractory differentiated thyroid cancer: a single center experience

W. Roll, B. Riemann, M. Schäfers, L. Stegger, A. Vrachimis; *University Hospital Münster, Münster, GERMANY.*

Aim: In general, differentiated thyroid cancer (DTC) patients treated by surgery and radioiodine therapy show excellent overall survival, however, radioiodine refractory DTC (RrDTC) patients suffer from a rather poor prognosis. In these situations new therapeutic options are warranted in addition to conventional external radiation therapy and surgery. To this end, novel systemic therapies such as tyrosine kinase inhibitors (TKIs) are promising, however, these are expensive and associated with serious adverse effects in more than one-fourth of patients. RrDTCs can also express somatostatin receptors, which could be employed for diagnostics and therapy using peptide radio-receptor therapy (PRRT). Hereby we present a single center experience of ^{177}Lu-DOTATATE therapy in advanced RrDTC. **Materials and Methods:** Five patients received 2 to 5 cycles

of PRRT with ^{177}Lu-DOTATATE (mean injected dose 7.0 GBq) between 5/2014 and 10/2016 in three month intervals. Inclusion criteria were RrDTC, no other therapy options as assessed by an interdisciplinary tumor board and positive ^{68}Ga-DOTATATE-PET-CT. Response to therapy was evaluated by interim and follow up ^{68}Ga-DOTATATE-PET-CT according to morphological (RECIST) and metabolic criteria (analogue to PERCIST). Additionally, thyroglobulin (Tg) levels were measured before each therapy cycle and after completion of therapy. Analysis was performed on a per-patient and per-tissue basis. **Results:** In post-therapy staging only one out of five patients (20%) showed partial response (decrease of > 30% in Tg, RECIST, and modified PERCIST), whereas three patients (60%) presented with progressive disease according to RECIST, PERCIST-like criteria and Tg levels. One patient (20%) had discordant findings regarding imaging (stable RECIST and modified PERCIST) and Tg levels (progression). On a per-tissue basis lymph node metastases and local recurrence showed more favorable results than bone metastases. **Conclusion:** In this cohort of 5 RrDTC patients, ^{177}Lu-DOTATATE therapy showed only limited efficacy, especially if bone metastases were present.

OP-106

Best Therapy Response vs Variability of Tumor Size, Absorbed Dose And Ki-67 Index After n.c.a. Lu-177 Dotatate Intra-arterial Infusions

M. Paphiti[1], I. Karfis[1], E. Z. Dimitriadi[2], S. Chondroyiannis[3], G. Nikou[1], V. Michalaki[1], G. Fragulidis[4], D. Voros[4], V. R. McCready[5], D. Rubello[3], G. S. Limouris[1]; [1]Medical Faculty, National and Kapodistrian University of Athens, Athens, GREECE, [2]Institute Claudus Regaud, University of Paul Sabatier, Toulouse, FRANCE, [3]Nuclear Medicine Department, Santa Maria della Misericordia Hospital, Rovigo, ITALY, [4]II Surgical Dept, of 'Aretaieion' Hospital, Medical Faculty, National and Kapodistrian University of Athens, Athens, GREECE, [5]Institute Cancer Research, Sutton Surrey & Royal Sussex County Hospital, Brighton, UNITED KINGDOM.

Introduction: GEP-NETs can be classified according to their Ki-67 proliferation index into grade 1 (G1), with a Ki-67 index <2%, G2 with a Ki-67 index between 3 and 20% and G3 > 20%. Focusing to liver metastasized disease, additional to the Ki-67 proliferation index the variability of tumor sizes in liver parenchyma crucially determine and contribute to their prognosis. Aiming to evaluate the tumor-volume impact on GEP-NETs response and prognosis, we compared and analyzed the correlation between their volume pattern and patients' survival. **Subjects and Methods:** We retrospectively studied a consecutive cohort of 13 patients with non-functioning, unresectable liver-metastatic GEP-NETs, undergoing intra-arterial infusions with non-carrier-added ^{177}Lu-DOTATATE (6 sessions each with 7.2 GBq per cycle, at standard intervals of about 2 mo). Patients (9, originated from pancreas and 4, from lungs) were graded as (G1/G2) and (G3) and were under long-acting somatostatin analog treatment. We classified the included patients in three groups as following: group A, with a liver metastasized tumor-size (LMTS) from 20 up to 30 mm (main diameter), group B, with a LMTS from 30 up to 40 mm and group C, with a LMTS larger than 40 mm. Response was evaluated according to RECIST criteria. Survival was analyzed according to Kaplan-Meier curve method. Cr-A was radioimmunologically measured and correlated with Ki-67 results. **Results:** The response rate regarding group A (6pts, mean tumor size 2-3cm, mean absorbed dose 450 Gy) was 50.0% as partial response, group B (3pts, mean tumor size 3-4cm, mean absorbed dose 150 Gy) was 70.0% as partial response and group C (4pts, mean tumor size 6cm, mean absorbed dose 450 Gy) was 20.0% as as stable disease. The median time of progression-free survival in group A was 53 mo, in group B, 58 mo and in group C 48 mo. Cr-A values showed a parallel to Ki-67 values, level. **Conclusion:** The final achievement to stabilize (SD) GEP-neuroendocrine liver metastasized tumours of large volume (about 6cm) after a radiobiological burden of 450 Gy (absorbed dose) compared to the partial response (PR) in pts with liver metastasized tumors of smaller volume with the same or even lower (150 Gy) absorbed dose, undeniably indicates the negative impact that the parameter volume plays, in PRRT response. The exeresis of these large volume tumors before PRRT should be a must.

M2M: New Targets

OP-107

Radiochemistry and Preclinical Evaluation of Two Novel Peptide Analogues Targeting Glucagon Receptor for Anti-Diabetic Drug Development

I. Velikyan[1,2], M. Bossart[3], T. Haack[3], I. Laitinen[3], P. Larsen[3], O. Plettenburg[4], L. Johansson[5], S. Pierrou[5], M. Wagner[3], O. Eriksson[5,6]; [1]PET Centre, Centre for Medical Imaging, Uppsala University Hospital, Uppsala, SWEDEN, [2]Section of Nuclear Medicine and PET, Department of Surgical Sciences, Uppsala University, Uppsala, SWEDEN, [3]Sanofi-Aventis, Frankfurt, GERMANY, [4]Helmholtz Zentrum, München, GERMANY, [5]Antaros Medical AB, Molndal, SWEDEN, [6]Uppsala University, Uppsala, SWEDEN.

Introduction: Type 2 diabetes affects hundreds of millions of individuals worldwide. The development of novel anti-diabetic therapies targeting glucagon receptors (GCGR) requires employment of imaging techniques that enable in vivo investigation of GCGR engagement by the therapeutic agent to facilitate stratification of candidate drugs. Two novel peptide analogues targeting GCGR were labelled with positron emitting Gallium-68 radionuclide for imaging using positron emission tomography (PET). **Methods:** Two glucagon peptide agonists, S01-GCG and S02-GCG were conjugated to a DOTA chelate moiety and labelled with Gallium-68 available from a [68]Ge/^{68}Ga generator system. The binding affinity and specificity of the resulting imaging agents, [^{68}Ga]Ga-DO3A-S01-GCG and [^{68}Ga]Ga-DO3A-S02-GCG, were investigated in vitro using GCG receptor transfected HEK293 cells and autoradiography on cryosections of liver tissue from rat, cynomolgus monkey

and human. The organ distribution, binding specificity, and dosimetry were studied in vivo in Sprague Dawley rats. **Results:** None-decay-corrected radiochemical yield was 56.9±1.3% and 61±2%, respectively for [⁶⁸Ga]Ga-DO3A-S01-GCG and [⁶⁸Ga] Ga-DO3A-S02-GCG providing specific radioactivity of 50.2±5.4 MBq/nmol and 64.9±2.1 MBq/nmol at the time of the respective experiments. Both agents demonstrated binding and internalization in GCGR transfected cells and liver sections, which was competed by excess of each respective peptide ligand or endogenous glucagon, but not endogenous GLP-1. Affinities for the human GCG receptor were 17±8 nM and >100 nM, respectively, and thus higher for [⁶⁸Ga]Ga-DO3A-S01-GCG. The in vivo uptake and retention in rat was highest in liver, spleen and kidney. The uptake in liver and spleen was competed by co-injection of 1 mg/kg of each respective peptide, indicating GCG receptor-mediated binding in these tissues. The liver uptake of [⁶⁸Ga]Ga-DO3A-S01-GCG was over 4-fold higher than that for [⁶⁸Ga]Ga-DO3A-S02-GCG. The displacement of [⁶⁸Ga] Ga-DO3A-S01-GCG and [⁶⁸Ga]Ga-DO3A-S02-GCG in liver were 84% and 56%, respectively. The extrapolation of rat dosimetry results to human showed comparable renal doses (0.54 mSv/ MBq and 0.48 mSv/MBq) and effective doses (20.2 μSv/MBq and 16.6 μSv/MBq), that would allow for multiple annual PET examinations in healthy individuals and individuals with type 2 diabetes without exceeding the limiting radiation absorbed doses. **Conclusions:** [⁶⁸Ga]Ga-DO3A-S01-GCG and [⁶⁸Ga]Ga-DO3A-S02-GCG analogues are promising candidate peptides for in vivo monitoring of GCG receptor occupancy in humans. However, further development towards clinical use will be focused on [⁶⁸Ga]Ga-DO3A-S01-GCG due to its higher affinity and superior displaceable binding in liver in vivo.

OP-108

Development of a new 68Ga radiolabelled PET imaging agent to evaluate in vivo expression of angiomotin in malignant brain tumors

A. Moyon[1,2,3], P. Garrigue[1,2,3], P. Brige[2], M. Nollet[1], L. Balasse[2], S. Fernandez[2], M. Blot-Chabaud[1], F. Dignat-George[1,3], B. Guillet[1,2,3]; [1]UMR_S1076 VRCM, Marseille, FRANCE, [2]CERIMED, Marseille, FRANCE, [3]APHM, Marseille, FRANCE.

This study aimed at evaluating angiomotin (AMOT) as a potential molecular target for diagnosis and targeting of glioblastoma, the most common and lethal brain malignancy. We recently developed a ⁶⁸Ga-radiolabelled PET imaging agent (AM007) for assessing tissular AMOT expression as a potential predictive marker of tissue regeneration in post-ischemic condition. Data from the literature argue for AMOT involvement in glioblastoma proliferation. On this basis, we performed the first **in vivo** evaluation of AMOT-targeting ⁶⁸Ga-radiolabeled radiotracer, compared to ⁶⁸Ga-NODAGA-RGD, in mice orthotopic glioblastoma xenografts models. Human glioblastoma xenografts were achieved by injecting 3.10⁵ U87 cells into the right caudate-putamen of 7-week-old male BALB/c athymic nude mice under 2% isoflurane anesthesia. NODAGA-conjugates of AM007 were synthetized and radiolabeled with ⁶⁸Ga (25°C for

15 minutes). Gallium was obtained in ⁶⁸Ga³⁺ form using a commercial TiO₂-based ⁶⁸Ge/⁶⁸Ga generator. μPET/CT imaging was performed 1h after the injection of 7±2MBq of ⁶⁸Ga-NODAGA-AM007 or ⁶⁸Ga-NODAGA-RGD, 21 days after xenograft. **In vivo** blocking experiment was performed by injecting a 100-fold excess of cold peptide 30min before ⁶⁸Ga-NODAGA-AM007 injection. ⁶⁸Ga-NODAGA-AM007 was produced with a radiochemical purity of 93.1%±2.0 (*n*=10) and stability in serum evaluated up to 2h at 90±1.5%. In healthy mice, ⁶⁸Ga-NODAGA-AM007 showed a rapid plasmatic clearance (6.0±2.0min) and a pharmacokinetic profile compatible with PET imaging. μPET/CT imaging of mice orthotopic glioblastoma xenografts showed a high ⁶⁸Ga-NODAGA-AM007 tumor uptake (1.58±0.70% ID/g; n=5) 1h after injection of the radiotracer. ⁶⁸Ga-NODAGA-AM007 tumor uptake was significantly higher (p=0,0035; n=5) than ⁶⁸Ga-NODAGA-RGD uptake (0.48±0.14%ID/g; n=5). A 100-fold excess of cold peptide significantly reduced the ⁶⁸Ga-NODAGA-AM007 uptake (69.9%±16.0%, p=0.0032, n=3) Post-mortem histological immunohistochemistry and western-blotting analysis confirmed significant expression of AMOT in U87 cells. Based on AMOT overexpression in U87 cells, the AMOT-targeting imaging agent, ⁶⁸Ga-NODAGA-AM007, showed a specific uptake in brain tumors using μPET imaging 21 days after implementation. This uptake was 3 times higher than ⁶⁸Ga-NODAGA-RGD, allowing us to speculate that ⁶⁸Ga-NODAGA-AM007 may be considered as a potential candidate for theranostic applications in glioblastoma.

OP-109

[¹¹C]Erlotinib as a PET radiotracer to measure OATP2B1 transport activity in the human liver

M. Bauer[1], A. Matsuda[1], B. Wulkersdorfer[1], C. Philippe[1], A. Traxl[2], C. Özvegy-Laczka[3], J. Stanek[1,2], L. Nics[1], S. Poschner[4], W. Jäger[4], G. Szakács[1,3], W. Wadsak[1,5], M. Hacker[1], M. Zeitlinger[1], O. Langer[1,2]; [1]Medical University of Vienna, Vienna, AUSTRIA, [2]AIT, Seibersdorf, AUSTRIA, [3]Hungarian Academy of Sciences, Budapest, HUNGARY, [4]University of Vienna, Vienna, AUSTRIA, [5]CBMed, Graz, AUSTRIA.

The liver is a major clearance organ for many drugs. The organic anion-transporting polypeptides (OATP) 1B1, 1B3 and 2B1, which are expressed in the basolateral membrane of hepatocytes, mediate the uptake of many drugs from blood into liver and play a crucial role in drug disposition. All currently available PET radiotracers to measure OATP transport activity in the liver are not OATP-subtype specific. In this study we identified the radiolabelled tyrosine kinase inhibitor [¹¹C]erlotinib as a hepatic OATP2B1-specific radiotracer. Hepatic disposition of [¹¹C] erlotinib was studied with PET in 6 healthy volunteers without and with oral pretreatment with a therapeutic erlotinib dose (300 mg). In parallel to PET imaging, arterial blood sampling was performed and data were analysed using pharmacokinetic modelling. **In vitro** transport experiments were performed with [¹¹C]erlotinib (< 0.1 μM) in cell lines overexpressing human OATP1B1, 1B3 or 2B1. In baseline PET scans there was a high uptake of [¹¹C]erlotinib into the liver (approximately 30% of the injected dose). Following erlotinib pretreatment the rate

constant for [^{11}C]erlotinib distribution to the liver was significantly decreased (-86%) with a concomitant increase in blood exposure, pointing to the involvement of a carrier-mediated hepatic uptake mechanism. *In vitro* transport experiments revealed that [^{11}C]erlotinib is at tracer concentrations exclusively transported by OATP2B1 and that transport is inhibited at therapeutic erlotinib concentrations. Our data suggest that at PET microdoses uptake of [^{11}C]erlotinib into the human liver is mediated by OATP2B1, whereas at therapeutic doses erlotinib inhibits its own transport by OATP2B1. [^{11}C]Erlotinib may be used as a hepatic OATP2B1-specific radiotracer and erlotinib as an OATP2B1 inhibitor in clinical drug-drug interaction studies, allowing the contribution of OATP2B1 to the hepatic uptake of drugs to be revealed.

OP-110

First in vivo imaging and in vitro studies of ^{18}F-DABTA in rat model with E46K alpha synuclein mutation

B. Hooshyar Yousefi[1], K. Shi[1], S. Reder[1], S. Reder[1], M. Herz[1], M. Braeuer[1], H. Wester[2], I. Yakushev[1], T. Arzberger[3], M. Schwaiger[1]; [1]Klinikum rechts der Isar, Technical university Munich, Munich, GERMANY, [2]LS Pharm. Radiochem., Technical university Munich, Munich, GERMANY, [3]Ludwig Maximilians Universität München, Munich, GERMANY.

Increased pathological aggregation of alpha-synuclein (a-syn) is considered as an early causal factor in the pathogenesis of Parkinson's disease and other alpha-synucleinopathies. A PET tracer quantifying a-syn would be invaluable for early diagnosis of alpha-synucleinopathies and clinical trials testing of therapeutic strategies aimed at lowering a-syn levels in the brain. Recently, we developed a promising ^{18}F-DABTA based on 4,4'-diaryl-2,2'-bithiazole as specific marker for noninvasive delineating a-syn as opposed to other proteopathies (e.g. Aβ and tau). In the present work, we focused on in vivo imaging and in vitro evaluation of ^{18}FDABTA by µPET using a-syn E46K mutant rat model at age of 12-16 moths. **Methods:** A library of 4,4'-diaryl-2,2'-bithiazole derivatives was synthesized and screened towards a specific marker for a-syn. The best candidate with Ki < 10 nM and high selectivity (110 fold) was selected and converted to its ^{18}F-labeled version for in vivo and in vitro evaluation. Then, its brain specific binding kinetics have been investigated using reference Logan model on dynamic PET and confirm by in vitro evaluations using rats with a-syn E46K mutation vs WT. **Results:** We stablished an automated twostep radiosynthesis of 18F-DABTA using Neptis module with RCY ≥15% and purity >98%. The tracer was directly used in our experiments with specific activity greater than 18 GBq/µmol. The binding potential of PET data showed significant PET signal increased in a-syn abundant regions substantia nigra, thalamus, cerebellum and brainstem, confirmed by histochemistry in rats with asyn E46K mutation vs WT. **Conclusion:** The favorable properties of this tracer e.g brain entry/clearance kinetics, target affinity, excellent accumulation in the a-syn rich regions and practicability of PET imaging in E46K rats suggests that it is the first promising selective a-syn tracer that may allow early diagnosis of αsynucleinop-

athies such as Parkinson's disease and dementia with Lewy bodies. The favorable features of this tracer encourage us to further evaluative it by NHP and translation into human studies.

OP-111

Targeting αvβ6-integrin with radiometallated peptides for therapy of pancreatic carcinoma

S. Färber[1], K. Steiger[2], F. Reichart[1], M. Schwaiger[2], H. Kessler[1], H. Wester[1], J. Notni[1]; [1]Technische Universität München, Garching, GERMANY, [2]Technische Universität München, München, GERMANY.

Introduction: In most adult tissues, expression levels of αvβ6-integrin are very low. It is upregulated in many carcinomas, such as ovarian, gastric, and squamous cell carcinoma, for which it is furthermore associated with invasive growth and a poor prognosis. **Methods:** The αvβ6-integrin selective RGD-nonapeptide c(FRGDLAFp(NMe)K*) was conjugated to different chelators (DOTA, DOTAGA, DOTPI) by means of amide bonding or Click Chemistry, the latter resulting in triazole-containing linkers. The conjugates were labeled with Ga-68 or Lu-177 and their octanol-PBS distribution coefficients determined by shake-flask method. Furthermore, they were evaluated in SCID mice bearing H2009 (human lung adenocarcinoma) xenografts by means of PET or biodistribution studies, respectively. αvβ6-integrin affinities were determined by means of ELISA on immobilised integrin. Immunohistochemical (IHC) analysis of β6-integrin expression was performed for the excised tumor xenografts, and furthermore for tissue microarrays containing human pancreatic ductal adenocarcinoma (PDAC, 383 primary tumors, 7 lymph node and 8 distant metastases) and 34 pancreatic intraepithelial neoplasia (PanIN) specimens. **Results:** While the Lu(III) complexes of all 5 conjugates exhibited comparable αvβ6-integrin affinities (IC50 ranging from 0.47±0.03 to 0.82±0.17 nM), the different formal charges of the featured chelate moieties (Lu-DOTA-monoamide: 0; Lu-DOTAGA: 1; Lu-DOTPI:4) resulted in strongly varying degrees of hydrophilicity of the Lu-177 labelled compounds (logD ranging from -3.0 to -4.1). Whereas PET studies showed substantial differences of the Ga-68 labeled compounds regarding tumor uptake and background level, biodistribution of the Lu-177 labeled species were quite similar and comparable to our previously reported αvβ6-integrin PET tracer Ga-68-Avebehexin. IHC analysis of a large number of patient tissue specimens confirmed a high prevalence of αvβ6-integrin expression in PDAC primaries (88%) and in almost all metastases, as well as in PanIN (57%), underscoring a high potential of αvβ6-integrin targeted radiopharmaceuticals for diagnosis and treatment of pancreatic cancer. **Conclusion:** Lu-177 labeled αvβ6-integrin targeting radiopeptides possess high potential for endoradiotherapy of carcinomas. We confirmed that almost all pancreatic cancers are characterized by αvβ6-integrin expression. Hence, our novel radiotherapeutics appear particularly suitable for treatment of PDAC. In view of a high mortality (5-year survival rate of only 8%) and limited therapy options for this cancer type, we anticipate substantial clinical impact of αvβ6-integrin-directed PRRT.

OP-112

Imaging beta cells in patients after Roux-en-Y gastric bypass (RYGB) surgery by ⁶⁸Ga-NODAGA-exendin-4 PET/CT

M. Boss, Sr.[1], L. N. Deden[2], E. O. Aarts[3], H. de Boer[3], I. M. C. Janssen[3], M. Brom[1], F. J. Berends[3], M. Gotthardt[1]; [1]Radboud University Medical Center, Nijmegen, NETHERLANDS, [2]Rijnstate hospital, Arnhem, NETHERLANDS, [3]Rijnstate Hospital, Arnhem, NETHERLANDS.

Background: After undergoing RYGB, remission of type 2 diabetes (T2D) occurs in >60% of patients. The mechanism behind this remission is incompletely understood. Beta cell activity (BCA) and beta cell mass (BCM) could play a role. While RYGB is beneficial for the health and quality of life of most patients, a rare complication is hyperinsulinemic hypoglycaemia. Also here the mechanism is unclear, but a role for BCA and BCM is hypothesized. Measuring BCA and BCM could provide useful information on the role of beta cells in patient responses to RYGB and possibly offer predictive value. Exendin-4, a stable analogue of glucagon-like peptide-1, specifically accumulates in the beta cells. ⁶⁸Ga-exendin-4 PET/CT can be used to quantify BCM *in vivo* and could help to study the role of BCM in changes in glycemic control after RYGB. **Methods:** BCA and BCM were compared between patients with different responses after RYGB. Patients with complete remission of T2D (responders) and without complete remission of T2D (non-responders) after RYGB were included as well as patients with hypoglycaemia after RYGB. BCA was measured by an arginine stimulation test and either an oral glucose tolerance test (in responders and non-responders) or a standard meal tolerance test (in the hypoglycaemia patients). BCM was measured in all patients as pancreatic uptake of ⁶⁸Ga-exendin-4 by quantitative analysis of PET/CT scans. **Results:** In total, 12 responders and 12 non-responders will be included. So far, five responders and five non-responders were included. Preoperative patient characteristics and postoperative weight loss were comparable between the groups. BCM was 37% lower in non-responders (131±78 kBq) compared to responders (206 ± 90 kBq), although not statistically significant (p = 0.25). BCA was significantly lower in the non-responders compared to the responders, with an arginine stimulated acute C-peptide response of 0.4±0.2 and 0.9±0.3 nmol/l, respectively (p = 0.02). In total, 8 hypoglycaemia patients and 8 matched controls will be included. At this moment, three hypoglycaemia patients have completed the study and in these patients the mean BCM was 226±69 kBq. **Conclusion:** These preliminary data show that measuring BCM in vivo is possible using ⁶⁸Ga-exendin-4 PET/CT. The data suggest that BCM is lower in patients with incomplete remission of T2D compared to those with complete remission. Furthermore, BCM in patients with hypoglycaemia seems to be higher than in patients with remission of T2D after RYGB. These data may suggest a role for BCM in patient response to RYGB.

OP-113

68Ga-Pentixafor PET/CT Imaging Targeting CXCR4 chemokine receptors : The First Clinical Experience in Lung carcinoma subtypes

A. Watts[1], B. Singh[1], S. Chutani[1], N. Dhanota[1], H. Singh[1], R. Basher[1], A. Bal[1], R. Kapoor[1], S. K. Arora[1], H. J. Wester[2], B. R. Mittal[1], D. Behera[1]; [1]PGIMER, Chandigarh, INDIA, [2]Technical University of Munich, Munich, GERMANY.

Objective: To evaluate the diagnostic utility of 68Ga Pentixafor PET/CT in lung carcinoma and to correlate tumor uptake of the radiotracer with CXCR4 tumor expression/density as a function of the tumor sub-type. **Materials and Methods:** Twenty-five patients (23M: 2F; mean age= 60± 10 yrs) with histopathologically proven lung carcinoma [Non-small cell lung carcinoma - NSCLC=19 (with squamous cell in 15, adenocarcinoma in 3; NOS in 1), Small cell lung carcinoma - SCLC in 3 and primary lung Neuroendocrine tumor- NET in 3] underwent 68Ga-Pentixafor PET imaging. Biopsied lung tissue samples were subjected to fluorescence-activated cell sorting (FACS) analysis using CD184 antibody. Mean Fluorescence Index (MFI) was documented as measure of CXCR4 receptor density. 68Ga PET/CT data was reconstructed and the estimated SUVmax values were correlated with FACS results for CXCR4 expression/density. About 110-150 MBq radioactivity of freshly prepared 68Ga-Pentixafor (synthesized by using Scintomics automated chemistry module procured under DST-FIST Project Funding) was administered intravenously. Whole body contrast enhanced CT (120Kv, 200-300mAs, Pitch 0.98:1, Slice thickness 3.75mm) followed by PET from skull to proximal thighs (3min/bed position; 7-8 positions) was acquired at 1-hour post injection. Data was reconstructed using iterative method (3 iterations, 28 sub-sets) and interpreted both visually and quantitatively. **Results:** The mean 68Ga-Pentixafor SUVmax value in squamous cell and adenocarcinoma patients was 6.3±1.5 (n=15) & 8.5±1.5 (n=3), respectively. The corresponding MFI value assessed in these patients was 118± 69 and 146±53, respectively. On the other hand, in SCLC patients (n=3), the mean SUVmax value was 10.4 ± 2.5 with MFI score of 151±59. In patients with primary lung NET disease (n=3), the mean SUVmax value was 5.1±0.03 with MFI score of 80 ± 26. Our results demonstrated that among NSCLC patients, a significantly higher SUVmax was seen in adenocarcinoma variant than in squamous cell and the higher uptake correlated with higher CXCR4 expression. In SCLC, SUVmax value was significantly higher than in NSCLC and NET patients and was associated with the higher CXCR4expression/density in SCLC patients. **Conclusion:** 68Ga-Pentixafor uptake directly correlates with CXCR4 expression in lung carcinoma. SCLC demonstrates higher CXCR4 expression as compared to NSCLC. This novel PET Tracer is anticipated to pave the way for the development of CXCR4 targeting radionuclide theranostics in advanced stage malignancies.

OP-114

Evaluation of Lu-177 Labelled 6A10 Fab as Carbonic Anhydrase 12 Targeting Agent

L. Fiedler[1], M. Kellner[2], A. Gosewisch[1], G. Böning[1], S. Lindner[1], P. Bartenstein[1], R. Zeidler[2,3], F. Gildehaus[1]; [1]Department of Nuclear

Medicine, LMU, Munich, GERMANY, [2]Research Group Prevention and Immunomodulation; Helmholtz-Zentrum, Munich, GERMANY, [3]Department of Otorhinolaryngology, LMU, Munich, GERMANY.

Introduction: Typical therapy of malignant gliomas consists of surgery, followed by radiation and chemotherapy. Because of their infiltrating behaviour, the glioma cells are spread in the tumor surrounding brain tissue, which leads to local recurrence. Treatment of these infiltrated cells is the aim of the locoregional radioimmunotherapy (RIT), which is maintained by direct application of the radioimmunoconjugate into the resection cavity. The membrane enzyme carbonic anhydrase 12 (CA12) is only expressed on glioma cells and not on healthy brain tissue, and therefore a promising target for RIT. In this study the CA12 specific binding agent 6A10 Fab radiolabelled with Lu-177 is evaluated for its application in RIT. **Methods:** CHO cells were transfected with Fab coding plasmids and 6A10 Fab was purified from the culture supernatant, modified with p-SCN-Bn-CHX-A´´-DTPA and radiolabelled with Lu-177. The conjugate was characterized by MALDI-TOF, FACS and radio-TLC. In-vitro stability studies in different media were performed. Biodistribution studies (1 h, 3 h, 6 h, 24 h, 48 h, n=4 each), autoradiography examinations and ex-vivo blocking experiments on tumor slices were carried out on xenotransplanted (glioma U87-cells) SCID-mice. The tumor was visualized in first imaging experiments using planar scintigraphy and SPECT-CT techniques. **Results:** MALDI-TOF analysis revealed a molar ratio of Fab to DTPA of 1:1. FACS analysis confirmed that the biological functionality of the 6A10Fab was not inhibited by modification and radiolabelling. High radiochemical purity of > 99% (1 mg Fab; 1.5 GBq Lu-177) was verified by radio-TLC. After an incubation time of 72 h, the radiochemical purity of the product in labelling buffer (RT), human plasma (37 °C) and cerebrospinal fluid (37 °C) was still > 90%. Biodistribution study shows a moderate tumor uptake of ≤3,1% ID/g at 3 h, with a maximum tumor/muscle ratio of 14,6 at 48 h p.i. Scintigraphy and SPECT-CT imaging showed good tumor uptake at 4 h p.i. Tumor autoradiography experiments revealed an expected inhomogeneous activity distribution. Tumor uptake was decreased by 49 % (n=8) after ex-vivo blocking experiments on tumor slices with 100-fold molar excess of unmodified 6A10. **Conclusion:** Because of its high radiochemical stability under physiological conditions and the specific CA12 binding ability in-vivo and in-vitro, Lu-177-6A10-Fab is a promising agent for the RIT of gliomas.

PSMA-targeting alpha-Radiation therapy with [225]Actinium-PSMA-617: Dosimetry, toxicity and duration of tumor-control

C. Kratochwil[1], F. Bruchertseifer[2], F. L. Giesel[1], C. Apostolidis[2], U. Haberkorn[1], A. Morgenstern[2]; [1]University Hospital Heidelberg, Heidelberg, GERMANY, [2]EC-JRC, Directorate for Nuclear Safety and Security, Karlsruhe, GERMANY.

Purpose: To evaluate the potential of [225]Ac-PSMA617 for PSMA-targeting alpha-therapy of poor-prognosis advanced-stage mCRPC patients. **Methods:** An appropriate starting activity for clinical application of [225]Ac-PSMA617 was defined by a preliminary dosimetry modeling. The treatment protocol was then refined by an empirical dose escalation with n=14 patients to define a "standard operation procedure". Consecutively an additional group of n=28 was treated following this protocol. PSA and radiological response were assessed. Duration of response was compared to the duration of tumor control of preceding treatment lines. Lab tests and clinical exam was done to assess toxicity. **Results:** Assuming a RBE of 5, a mean dose of 2.3 Sv for salivary glands, 0.7 Sv for kidneys and 0.05 Sv for red marrow were estimated for 1 MBq of [225]Ac-PSMA617; comparable to an activity of 1 GB of ^{177}Lu-PSMA617. In dose-escalation phase, severe xerostomia became dose-limiting and defined the MTD even before relevant hematological toxicity was observed. 100kBq/kg BW [225]Ac-PSMA617 administered every 2 months was chosen as a first SOP. From 28 patients "intention-to-treat", n=20 were finally treated "per-protocol" and n=15 of them (75%) demonstrated a PSA and radiological response after a follow-up period of 6 months. Complete remission was observed in n=4 patients (20%). Due to early progression n=3 patients discontinued therapy at an earlier time-point, n=5 patients discontinued due to xerostomia. No grade-3/4 hematological toxicity was observed for patients with grade-0/1 values at baseline, regardless of the extent of bone involvement. PFS under PSMA-TAT was longer than the mean duration of tumor control under preceding treatment lines. **Conclusions:** First clinical results imply that PSMA-targeting alpha-radiation therapy with 225Ac-PSMA617 benefits from favorable low hematological toxicity even in "superscan"-pattern patients and also present remarkable anti-tumor activity in regard to objective response and PFS.

OP-117

68Ga-PSMA PET/CT to restage prostate cancer after radical therapy. Results of a prospective single-center trial

F. Ceci[1], P. Castellucci[2], T. Graziani[2], A. Farolfi[2], R. Renzi[2], R. Schiavina[3], M. Borghesi[3], F. Lodi[2], S. Boschi[2], S. Fanti[2]; [1]Department of Surgical Sciences, University of Bologna, Bologna, ITALY, [2]Nuclear Medicine, S.Orsola-Malpighi Hospital, University of Bologna, Bologna, ITALY, [3]Department of Urology, S.Orsola-Malpighi Hospital, University of Bologna, Bologna, ITALY.

Aim: The primary objective is to evaluate the performance of 68Ga-PSMA-PET/TC for detecting the site(s) of disease relapse in prostate cancer (PCa) with biochemical recurrence (BCR) after primary treatment. **Material and Methods**: This prospective single-center trial was approved by the Local Ethical Committee (PSMA-PROSTATA; Eudract: 2015-004589-27 OsSC). Inclusion criteria were: 1) proven PCa; 2) radical therapy (surgery or radiotherapy) for localized PCa; 3) proven BCR 4) PSA values comprised between 0.2-2ng/mL; 5) Gleason Score ≥7. From March 2016 to March 2017 were enrolled 257 patients (mean age= 68,7 years-old) matching all the inclusion criteria. This calculated sample size was adequate to evaluate the diagnostic accuracy of 68Ga-PSMA-PET/CT in a homogenous cohort of recurrent patients. The 96,5% were treated with radical prostatectomy, while the 3,5% with radical radiotherapy. The 10,1% of patients were treated with androgen-deprivation therapy at the time of PET/CT, while the 23,7% received salvage treatments during BCR. The mean PSA value at the time of the scan was 0,81 ng/mL (median-PSA=0,60 ng/mL; range=0,2-2 ng/mL). Correlative imaging with choline-PET/CT or MRI was available in the 72,3% of patients. **Results**: 68Ga-PSMA-PET/TC resulted positive, detecting at least one site of suspected PCa metastasis, in 117/257 patients, consisting in an overall detection-rate of 45,5%. On a patient-based analysis, local lesions limited to the pelvis (prostate/prostate bed and/or pelvic lymph-nodes) were detected in 57/257 patients (22,2%). The presence of at least one distant lesion (retroperitoneal or distant lymph-nodes and/or bone lesions and/or visceral lesions) was detected in 60/257 patients (23,3%). The mean PSA was significantly higher (p<0,05) in PET-positive patients (mean=0,97;median=0,86 ng/mL) vs. PET-negative patients (mean=0,68;median=0,50 ng/mL). PSA doubling-time resulted in the multivariate-analysis as statistical significant predictor for a positive 68Ga-PSMA-PET/CT scan (p<0,01). Correlative imaging with choline-PET/CT or MRI was available in 91/117 PET-positive patients resulted negative/inconclusive in the 69,2% (63/91) of cases. **Conclusion**: the results of this prospective trial confirmed the importance of 68Ga-PSMA-PET/TC for restaging PCa patients during BCR. In a homogeneous cohort of highly selected recurrent PCa patients, with a mean PSA value of 0,81 ng/mL, 68Ga-PSMA-PET/TC proved a dection-rate of 45,5%, with an incidence of systemic lesion detected in the 23,3% of cases. The validation of this new procedure in the clinical setting and its comparison with histology and/or other techniques would facilitate the routine implementation of this modality.

OP-118

Integrated 68Ga-PSMA-11 PET/MRI enhances discriminatory power of multi-parametric prostate MRI

M. Al-Bayati[1], J. Grueneisen[1], S. Lütje[1], L. Sawicki[2], S. Suntharalingam[1], S. Tschirdewahn[1], M. Forsting[1], K. Herrmann[1], L. Umutlu[1], A. Wetter[1]; [1]University Hospital Essen, Essen, GERMANY, [2]University Hospital Duesseldorf, Duesseldorf, GERMANY.

Purpose: To evaluate diagnostic accuracy of integrated 68Ga-PSMA-11 PET/MRI in patients with primary prostate cancer as compared to multi-parametric MRI. **Material and Methods:** A total of 22 patients with recently diagnosed primary prostate cancer underwent clinically indicated 68Ga-PSMA-11 PET/CT for initial staging followed by integrated 68Ga-PSMA-11 PET/MRI. Images of mpMRI, PET and PET/MRI were evaluated separately by applying PIRADSv2 for mpMRI and a 5-point Likert scale for PET and PET/MRI. Results were compared with pathology reports of biopsy or resection. Statistical analyses including ROC analysis were performed to compare the diagnostic performance of mpMRI, PET and PET/MRI. **Results:** PET and integrated PET/MRI demonstrated a higher diagnostic accuracy than mpMRI (AUC: mpMRI: 0.679, PET and PET/MRI: 0.951). The proportion of equivocal results (PIRADS 3 and Likert 3) was considerably higher in mpMRI than in PET and PET/MRI. In a notable proportion of equivocal PIRADS results, PET led to a correct shift towards higher suspicion of malignancy and enabled correct lesion classification. **Conclusion:** Integrated 68Ga-PSMA-11 PET/MRI demonstrates higher diagnostic accuracy than mpMRI and is particularly valuable in tumours with equivocal results from PI-RADS classification.

OP-119

Tc-99-MIP-1404 Imaging for the Detection of PSMA-Positive Lesions. A Pilot Study in 380 Patients with Histologically Confirmed Prostate Cancer

C. Schmidkonz, P. Ritt, C. Hollweg, M. Beck, T. I. Goetz, J. Sanders, J. Reinfelder, D. Schmidt, T. Kuwert; Universitätsklinikum Erlangen, Erlangen, GERMANY.

Introduction: Tc-99m-MIP-1404 (Progenics Pharmaceuticals, Inc., New York, NY) is a novel, SPECT- compatible Tc-99m-labeled PSMA inhibitor- for the detection of prostate cancer. We present first results of its clinical use at our institution for a cohort of 380 men with histologically confirmed prostate cancer. **Methods:** Tc-99m-MIP1404 scintigraphy was performed in 380 patients. Of these, 200, 95, and 85 were referred due to PSA relapse, for primary staging, and for restaging under therapy, respectively. Whole-body planar scintigraphy and SPECT/CT of the lower abdomen and thorax were carried out at 3 to 4 hours p.i. of 710 ± 64 Tc-99m-MIP-1404. Images were visually analyzed for presence, location and extent of abnormal uptake. In addition, quantitative analysis of the SPECT/CT data was carried out in a subset of 105 patients. Follow-up reports of subsequent therapeutic interventions were available for 58% (223) of all patients. **Results:** In total, tracer positive lesions were detected in 75% (286/380) of all patients. In 27% (104) of patients, uptake in the primary tumor was found. Local recurrence was diagnosed in 10% (37). Metastases in lymph nodes, bone, lung and other locations were detected in 37% (141), 30% (113), 4% (16), 5% (20), respectively. Detection rates were 89% at PSA levels greater than or equal to 2 ng/ml and 40% below that threshold. Quantitative analysis of PSMA-positive lesions disclosed SUV max values of on average 18.7±27.6 (0.8-262.9) and tumor-to-normal ratios of 100.7±173.9 (4.9-1325.4). The PSA level correlated significantly with total uptake of MIP-1404 in tumors (Spearman-Rho 0.64, p<0.001) and with tumor volume

(Spearman-Rho 0.47, p<0.001). The PSA level was significantly higher in patients with PSMA-positive lesions (Wilcoxon rank-sum, p<0.001). Following MIP-1404 imaging, in 76% (169/223) of those patients for whom follow-up was available therapeutic strategy was changed. These changes included initiation or adjustment of anti-androgenic therapy in 50, radiation therapy in 61, surgery in 33, initiation of chemotherapy in 10, Lu-177-PS-MA therapy in 6, and Ra-223-dichloride therapy in 9 patients. Of all patients undergoing surgery, histopathological results were available to us in 28 cases and confirmed the diagnoses of MIP-1404 imaging. **Conclusion:** SPECT/CT with MIP-1404 has a high accuracy in detecting PSMA-positive lesions in patients with elevated PSA values and has considerable therapeutic impact. Quantitative analysis showed significant correlation between PSA level, total uptake and tumor volume. Tumor-to-normal ratios are higher than those published for bone metastases of prostate cancer and Tc-99m-DPD, which could result in higher detection rates.

OP-120

Correlation Between Uptake of ^{18}F-1-amino-3-fluorocyclobutane-1-carboxylic acid (^{18}F-fluciclovine) and Expression of Amino Acid Transporters ASCT2 and LAT1 in prostate cancer

M. Kim[1,2,3], I. Saarinen[4], A. Kuisma[5], I. Jambor[6,7], J. Kemppainen[8], E. Kähkönen[9], A. Koskenniemi[10], P. Taimen[4], H. Minn[5]; [1]Gunma University, Maebashi, JAPAN, [2]Turku PET Centre, University of Turku, Turku, FINLAND, [3]Japan Society the promotion of science, Tokyo, JAPAN, [4]Department of Pathology, University of Turku and Turku University Hospital, Turku, FINLAND, [5]Turku University Hospital, Turku, FINLAND, [6]Turku University Hospital, Departments of Oncology and Radiotherapy, Turku, FINLAND, [7]Department of Radiology, Baystate Medical Center, University of Massachusetts, Springfield, MA, UNITED STATES OF AMERICA, [8]Turku University Hospital, Departments of Nuclear Medicine, Turku, FINLAND, [9]Turku University Hospital, Departments of Urology, Turku, FINLAND, [10]Turku University Hospital, Departments of Pathology, Turku, FINLAND.

Aim: ^{18}F-1-amino-3-fluorocyclobutane-1-carboxylic acid (^{18}F-fluciclovine) was recently approved by FDA for detection of recurrent prostate cancer (PCa). We aimed to evaluate expression of neutral amino acid transporter 2 (ASCT2) and L type amino acid transporter1 (LAT1) in prostatic tissue for their impact on uptake of ^{18}F-fluciclovine in localized PCa. **Materials and Methods:** Twenty-five patients with histologically confirmed PCa underwent PET/CT before robotic-assisted laparoscopic prostatectomy. Imaging was performed immediately after injection of 369 ±10 MBq of ^{18}F-fluciclovine and the uptake in PCa was expressed as SUV$_{max}$ 12-22 min from injection. Based on whole mount prostatectomy samples, the index tumours representing Gleason Scores (GS) 3+4=7 (n=10), 4+3=7 (n=8), 4+4=8 (n=1), 4+5=9 (n=4) and 5+4=9 (n=2)were selected for analysis. The expression of ASCT2 and LAT1 was studied with immunohistochemistry (IHC) in a tissue microarray (TMA) including three 1 mm cores from each patient's index tumor and one core of benign tissue from the same patient as a control. The TMA slides were scored independently by two persons based on visual intensity of carcinoma cells as follows: score 0 (negative staining), 1 (low intensity), 2 (moderate intensity) or 3 (high intensity). **Results:** The ^{18}F-fluciclovine uptake (SUV$_{max}$) in index tumour and ASCT2 score had a significant correlation (r=.468; P=.021), while that between SUV$_{max}$ and LAT1 was not (r=.250; P=.119). SUV$_{max}$ correlated with GS (r=0.435; P=0.030), while expression of amino acid transporters ASCT2/LAT1 did not show a relationship with GS. **Conclusions:** Our findings indicate that ^{18}F-fluciclovine PET/CT predicts GS and may thus assist in planning of local therapies. ASCT2 may be more important than LAT1 in mediating uptake of ^{18}F-fluciclovine in PCa.

OP-121

Impact of Ga-68 PSMA PET/CT on radiation treatment planning of prostate cancer

S. M. Schwarzenboeck[1], L. Schubert[1], H. Rennau[2], J. Kurth[1], B. J. Krause[1], G. Hildebrandt[2]; [1]Department of Nuclear Medicine, Rostock University Medical Centre, Rostock, GERMANY, [2]Department of Radiotherapy, Rostock University Medical Centre, Rostock, GERMANY.

Purpose: Radiation treatment (RT) is clinically established in PSA persistence/biochemical recurrence (BCR) as well as in primary prostate cancer (PC) as curative treatment. The aim of the study was to assess the impact of 68-Ga-PSMA PET/CT on RT planning in patients with BCR and high risk (HR) PC. **Patients and Methods:** 38 patients with BCR after radical prostatectomy (n = 27) and HR PC (n= 11) with a median PSA of 1.15 ng/ml (range 0.17-12.1) and 5.2 ng/ml (range 0.84-15.7), respectively, underwent 68-Ga-PSMA PET/CT before RT. Influence of 68-Ga-PSMA PET/CT on the extent of planning target volume (PTV) (compared to conventional PTV) and addition of PET-based boosts were assessed. 10/27 (BCR) and 5/11 patients (HR PC) were under androgen deprivation therapy during RT. Median clinical follow up of 12 months (range 3-24) was available in all patients. **Results:** 68-Ga-PSMA PET/CT was positive in 23/38 (60.5%) of patients (8/23: local recurrence (LR), 11/23: nodal recurrence/metastasis (not detected by CT, lymph node diameter≤10 mm), 1/23: LR and nodal recurrence, 2/23: solitary bone metastasis, 1/23: combined oligometastatic nodal/bone metastases). In BCR primary PTV was changed in 16/27 patients extending PTV to the lymphatic drainage (10/16), to PSMA-positive LR (3/16), bone metastases (2/16) and to both nodal/bone metastases (1/16). PET-based increase of primary PTV was 116% (median administered dose of 45 Gy (range 45-66.6)). Additional PET-based boosts were administered in 19/27 patients (local in 8/19, nodal in 10/19, both in 1/19), median boost volume was 31.3 cm3 (range 17.2-80.2) (local) and 19.7 cm3 (range 3.0-109.3) (nodal) with a median boost dose of 5.6 Gy (range 5.4-19.8) (local) and 23.1 Gy (range 5.4-34.8) (nodal). In HR PC treatment was changed in 1/11 (9%). Primary PTV was extended to the lymphatic drainage (additional RT volume of 644.5 cm3, 45 Gy), additional boost was administered to one PSMA-positive lymph node (volume of 2.7 cm3, 23.1 Gy). All patients showed biochemical response (mean

PSA decrease 88.8 +/- 14.0%). Nadir PSA was reached 10 months (range 1-17) after end of RT (median 0.07 ng/ml, range 0.002-3.96). Within a median follow-up of 12 months (range 3-22 and 8-24 in BCR and HR PC, respectively), median PSA was 0.05 ng/ml (range 0.002-8.5) (BCR) and 0.26 ng/ml (range 0.02-2.68) (HR PC). **Conclusion:** 68-Ga-PSMA PET/CT influenced RT planning in almost 63% of BCR and 9% of HR PC patients by change of PTV and addition of boosts.

OP-122

[⁶⁸Ga]Ga-PSMA-PET/CT imaging of localized prostate cancer patients for intensity modulated radiation therapy treatment planning with integrated boost

*L. Thomas[1], S. Kantz[2], A. Hung[3], D. Monaco[3], F. C. Gaertner[4], H. Strunk[5], M. Essler[4], C. R. Thomas[3], W. Laub[3], **R. A. Bundschuh[4]**; [1]Department of Nuclear Medicine, Universitaetsklinikum Bonn; Department of Radiation Medicine, Oregon Health and Science University, Portland, OR, UNITED STATES OF AMERICA, [2]LMU Munich, Department of Radiation Oncology, Munich, GERMANY, [3]Department of Radiation Medicine, Oregon Health and Science University, Portland, OR, UNITED STATES OF AMERICA, [4]Department of Nuclear Medicine, Universitaetsklinikum Bonn, Bonn, GERMANY, [5]Department of Radiology, Universitaetsklinikum Bonn, Bonn, GERMANY.*

Introduction: High-precision radiation treatment is a curative option for patients with prostate carcinoma. To improve tumour control and reduce local side effects different boost approaches are available. In this study we investigated the use of ⁶⁸Ga-PSMA-PET/CT for such treatment options and the potential gain for local tumour control and dose to organs at risk (OAR). **Methods and Materials:** 21 patients with histologicaly proven prostate cancer without previous therapy underwent ⁶⁸Ga-PSMA-PET/CT. Body contour and OAR were manually defined. PTV70 was defined as planning target volume (PTV). A PET positive volume PTV_PET was defined using an autocontouring method based on a threshold of 40% of the maximum activity in the lesion. Five treatment plan variations ranging from 70Gy on PTV70 over integrated boost plans to 95Gy just on PTV_PET were calculated for each patient (Monaco, Elekta, USA - s. table attached). Analysis of derived treatment plans was done according to QUANTEC with an in-house developed software. TCP (Tumor Control Probability) and NTCP (Normal Tissue Complication Probability) for rectum and bladder were calculated. Student's t-test method was applied for statistical analysis (paired, two-sided, p<0.05 was considered as statistically significant). **Results:** Comparing the conventional plans to the plans with integrated boost and plans just treating the PET-positive volume, we find that the TCP increased to (95.2±0.5)% for an integrated boost with 75.6Gy, (98.1±0.3)% for an integrated boost with 80Gy, (94.7±0.8)% for treatment of the PET-positive volume with 75Gy, and to (99.4±0.1)% for treating the PET-positive volume with 95Gy (all p<0.0001). For the integrated boost with 80Gy a significant increase of the median NTCP of the rectum was found, for all other plans no statistical significant increase in the NTCP neither of the rectum nor the bladder was found. Compared to their *Pros-*

tate plan results, patients with a tumour directly adjacent to the rectum wall were found to have a significantly higher NTCP_rectum if the PTV_PET was boosted. At the same time of course, these patient's median TCP of the PET-positive volume was found to be significantly improved as well. **Discussion and Conclusion:** Our study demonstrates that the use of ⁶⁸Ga-PSMA-PET/CT would allow for more individualized prostate treatment planning and better targeting of active tumour volumes. TCP values of active tumour volumes can be increased, while rectum and bladder NTCP values either remain the same or are even lower. Clinical studies should be performed to confirm the theoretical benefits of PET target optimized treatment planning.

OP-123

Intra-individual comparison of 18F-labelled PSMA-1007-PET/CT, mpMRI and radical prostatectomy specimen in patients with primary prostate cancer

*C. Kesch[1], M. Vinsensia[2], J. P. Radtke[1,3], H. P. Schlemmer[3], M. Heller[4], E. Ellert[5], T. Holland-Letz[6], S. Duensing[4,1], N. Grabe[7,8], A. Afshar-Oromieh[2], K. Wieczorek[5], M. Giesel[2]**; [1]Department of Urology, University Hospital Heidelberg, Heidelberg, GERMANY, [2]Department of Nuclear Medicine, University Hospital Heidelberg, Heidelberg, GERMANY, [3]Division of Radiology, German Cancer Research Center (DKFZ), Heidelberg, GERMANY, [4]Section of Molecular Urooncology, Department of Urology, University of Heidelberg, Heidelberg, GERMANY, [5]Institute of Pathology, University Hospital Heidelberg, Heidelberg, GERMANY, [6]Division of Biostatistics, German Cancer Research Center (DKFZ), Heidelberg, GERMANY, [7]Department of Medical Oncology, National Center for Tumor Diseases (NCT), University Hospital Heidelberg, Heidelberg, GERMANY, [8]Hamamatsu Tissue Imaging and Analysis Center, University of Heidelberg,, Heidelberg, GERMANY, [9]Division of Radiopharmaceutical Chemistry, German Cancer Research Center (DKFZ), Heidelberg, GERMANY, [10]Department of Urology, University Hospital Essen, Essen, GERMANY.*

Introduction: ⁶⁸Ga-prostate-specific membrane antigen (PSMA)-11-positron-emitting-tomography (PET)/computer-tomography (CT) represents and advanced method for diagnosis of recurrent or metastatic prostate cancer but has limitations due to short half life of ⁶⁸Ga, narrow availability and urinary clearance. Objective: To examine the value of the new PET tracer ¹⁸F-PSMA-1007 for staging of local disease by comparing it to multi parametric magnetic resonance imaging (mpMRI) and radical prostatectomy (RP) histopathology. **Materials and Methods:** In 2016, ¹⁸F-PSMA-1007-PET/CT was performed in 10 men with biopsy confirmed high-risk prostate cancer (PCa). 9 patients underwent mpMRI in the process of primary diagnosis. Consecutively, RP was performed in all 10 men. Agreement analysis was performed retrospectively. PSMA-staining was added for representative sections in RP specimen slices. Localization and agreement analysis of ¹⁸F-PSMA-1007-PET/CT, mpMRI and RP specimen was done dividing the prostate into 38 sections as described in PI-RADS v2. Sensitivity (SE), specificity (SP), positive predictive value (PPV), negative predictive value (NPV) and

accuracy were calculated for total and near total agreement. **Results:** ^{18}F-PSMA-1007-PET/CT had a 68.2% NPV and 75.3% accuracy and mpMRI had 88.2% NPV ans 72.5% accuracy for total agreement. Near total agreement analysis resulted in an NPV of 91.1% and an accuracy of 92.6% for ^{18}F-PSMA-1007-PET/CT and 90.0% and 87.4% for mpMRI, respectively**. Conclusion:** The comparison with RP histopathology demonstrated that ^{18}F-PS-MA-1007-PET/CT is a very promising method to determine local staging of PCa.

OP-124

^{68}Ga-PSMA PET/CT for restaging prostate cancer patients with early biochemical recurrence and PSA values lower than 0,5 ng/mL

A. Farolfi[1], F. Ceci[1], T. Graziani[1], P. Castellucci[1], L. Esposito[1], A. Lambertini[1], E. Lodi Rizzini[1], R. Schiavina[2], F. Lodi[1], S. Fanti[1]; [1]Nuclear Medicine Unit, S.Orsola-Malpighi Hospital, University of Bologna, Bologna, ITALY, [2]Department of Urology, S.Orsola-Malpighi Hospital, University of Bologna, Bologna, ITALY.

Aim: To evaluate the diagnostic value of ^{68}Ga-PSMA-PET/CT in prostate cancer (PCa) patients with biochemical relapse (BCR) after radical prostatectomy (RP) showing prostate-specific antigen (PSA) lower than 0.5 ng/mL. **Materials and Methods:** ^{68}Ga-PSMA-PET/CT is performed in our institution as investigational procedure in PCa patients, within a prospective trial (Eudract: 2015-004589-27 OsSC). Within this cohort we retrospectively selected patients treated with RP as primary treatment, with at least 7 as Gleason Score (GS) and presenting BCR with PSA values comprised between 0.2 and 0.5 ng/mL. According to these criteria a total of 100 PCa patients were enrolled in the present analysis (mean age 66; range 53-79). Mean PSA value before ^{68}Ga-PSMA PET/CT was 0.32 ng/mL (median 0,31; SD ±0.09). 7% (7/100) were treated with androgen-deprivation therapy at the time of the scan, while 19% (19/100) already received salvage therapy during BCR. Data about clinical history, correlative imaging and PSA kinetics were all recorded and collected. **Results:** ^{68}Ga-PSMA PET/CT resulted positive in 29/100, thus resulting in an overall detection rate of 29%. ^{68}Ga-PSMA uptake was observed in the prostatic bed (2/100; 2%), in pelvic lymph nodes (14/100; 14%), in distant (retroperitoneal and above iliac-bifurcation) lymph nodes (4/100; 4%) and in bone (17/100; 17%). Multiple bone lesions (≥2 bone lesions) were observed in 6/100 patients (6%). 23/100 patients had a negative re-staging Choline-PET/CT and the 30.4% of them had a positive ^{68}Ga-PSMA scan (7/23). 19/100 patients had a negative re-staging MRI scans and the 21.1% of them had positive ^{68}Ga-PSMA (4/19). Among the 29/100 patients with positive ^{68}Ga-PSMA-PET/CT, 8/29 performed also re-staging Choline-PET/CT (1 positive and 7 negative), whereas 8/29 performed re-staging MRI (4 positive and 4 negative). No positive scans with other diagnostic procedure were recorded in PSMA negative patients. **Conclusions:** In our patient-series with PSA<0.5 ng/ml (mean PSA=0,32 ng/mL), it was observed a detection rate of 29% for ^{68}Ga-PSMA-PET/CT. According to these data, ^{68}Ga-PSMA-PET/CT is a feasible procedure and may play a role in disease re-staging, also with very low PSA levels, since one third of patients of this patient-series may benefit during the early phase of BCR detecting local or distant PCa relapse. As a consequence, these patients could be referred to metastases-directed therapy according to PET/CT results. Finally, it is notable that in this patient-series the 17% of patients presented PSMA uptake in the bone suspected for skeletal metastases.

OP-125

Oligometastatic Prostate Cancer radiotherapy treatment based on ^{68}Ga-PSMA PET/CT: preliminary results

C. Artigas[1], C. Florian[1], D. Van Gestel[1], D. Van Gestel[2], P. Flamen[1], F. Otte[1]; [1]Jules Bordet Institut, Brussels, BELGIUM, [2]Jules Bordet Institut Brussels, Brussels, BELGIUM.

Introduction and Aim: Oligometastatic disease in patients with prostate cancer (PCa) biochemical relapse (BCR) after primary treatment with curative intent is defined as the presence of up to 3 metastatic sites. Treating those lesions with stereotactic body radiotherapy (SBRT) has been demonstrated to increase disease free survival in a safe way, delaying androgen deprivation therapy for more than 2 years. However, those studies have been performed staging patients with Choline-PET. Our hypothesis is that these results can be improved using ^{68}Ga-PSMA PET/CT, which has demonstrated better accuracy in patients with BCR at low PSA levels, where the probability of oligometastatic disease is higher . The aim of this communication was to assess the efficacy of SBRT based on ^{68}Ga-PSMA PET/CT in patients with BCR. **Material and Methods:** This is a retrospective analysis of a monocentric cohort of PCa patients diagnosed with oligometastatic disease based on ^{68}Ga-PSMA PET/CT findings and treated with RT. Inclusion criteria were: histologically proven PCa, BCR after local treatment with curative intent (surgery, radiotherapy or both) and 3 or less metastatic lesions. Number and localization of metastatic sites where registered. MRI and CT coregistration were used for SBRT planning. In order to evaluate its efficacy , biochemical response was defined as a decrease of >50% of PSA (PSA$_{50}$) measured at 1 and 4 months after SBRT. Patients were followed-up until progression. **Results:** From a total cohort of 45 patients treated with RT based on ^{68}Ga-PSMA PET/CT results, 15 met the inclusion criteria. Median PSA value at the time of the scan was 2.06ng/ml. A total of 22 PSMA positive lesions were treated: 13/22 (59%) lymph nodes, 6/22 (27%) bone lesions and 3/22 (14%) lung lesions. Only 1/15 (7%) patients had a biochemical response (PSA$_{50}$) at 1 month while 8/11 (73%) patients presented a biochemical response at 4 months of follow-up . At the moment of this communication 4 patients are still responding at 1 year follow-up with no androgen deprivation therapy needed. **Conclusion:** Retrospective study preliminary results suggest SBRT based on ^{68}Ga-PSMA PET/CT to be an effective treatment in patients with PCa oligometastatic disease. Biochemical response seems to be uncomplete at 1 month and should therefore be evaluated at earliest 4 months after SBRT. Future studies measuring outcome of SBRT based on ^{68}Ga-PS-MA PET/CT should be confronted to those using other imaging techniques.

OP-126

Impact of ^{68}Ga-PSMA-11 PET/CT on salvage radiotherapy planning in post-prostatectomy patients with early biochemical recurrence

J. Calais[1], J. Czernin[1], W. P. Fendler[1,2], K. Herrmann[1,3], I. Rauscher[4], N. Hegemann[2], T. Poeppel[3], M. Cao[1], M. Eiber[1,4], N. Nickols[1]; [1]UCLA, LOS ANGELES, CA, UNITED STATES OF AMERICA, [2]Ludwig-Maximilians-University, Munich, GERMANY, [3]Universitätsklinikum Essen, Essen, GERMANY, [4]Klinikum rechts der Isar, Technical University of Munich, Munich, GERMANY.

Objectives: One main curative option for post-prostatectomy patients with biochemical recurrence is salvage radiation therapy (SRT). However up to 50% of patients treated with SRT will experience disease progression. Most prior clinical trials evaluating SRT targeted the prostate bed only. The benefit of pelvic lymph node irradiation is controversial and under investigation. ^{68}Ga-PSMA-11 PET/CT has proven to detect sites of recurrence with a higher accuracy than any other imaging modality especially at serum PSA levels of < 1 ng/ml. The aim of our study was to determine whether ^{68}Ga-PSMA-11 PET/CT localizes biochemical recurrence sites after primary surgery in patients eligible for early SRT (PSA<1 ng/ml) and how this imaging approach affects SRT planning. **Methods:** A multicenter retrospective analysis was performed on 252 men who underwent ^{68}Ga-PSMA-11 PET/CT between August 2013 and February 2017 for biochemical recurrence after initial radical prostatectomy. Four institutions participated in the study: Technical University of Munich (n=147), Ludwig-Maximilians-University, Munich (n=40), Essen University Hospital (n=36) and University of California Los Angeles UCLA (n=29). Inclusion criteria were biochemical recurrence with PSA<1 ng/ml and no prior radiotherapy. Clinical data and DICOM files of all patients were anonymized and imported on a dedicated radiotherapy workstation (MIM software). First, radiotherapy target volumes were delineated on the CT in accordance with RTOG contouring guidelines. Secondly, the ^{68}Ga-PSMA-11 PET was co-registered and target volumes were displayed in the fused ^{68}Ga-PSMA-11 PET/CT to visually assess potential differences between standard CT and ^{68}Ga-PSMA-11 PET/CT derived target volumes as a measure of impact on SRT planning. **Results:** The median PSA level was 0.45 ± 0.25 (range 0.03-1). ^{68}Ga-PSMA-11 PET/CT revealed local recurrence as the only site of recurrence in 38 (15%) patients. Pelvic nodal recurrence, extra-pelvic nodal recurrence, bone metastases and visceral metastases were present in 82 (33%), 3 (1%), 22 (9%) and 3 (1%) patients, respectively. A major impact on initial SRT planning by ^{68}Ga-PSMA-11 PET/CT occurred in 138 patients (55%): pelvic nodal radiotherapy for N1 disease in 71 (28%) patients, extension of standard RTOG target volumes in 40 (16%) patients and contraindication of SRT because of distant metastases in 27 (11%) patients. Moreover, metastasis-directed stereotactic body radiotherapy for oligometastatic disease was possible in 13 (5%) patients. **Conclusion:** ^{68}Ga-PSMA-11 PET/CT has significant impact (55%) on SRT planning in patients with early biochemical recurrence (PSA < 1ng/ml) after radical prostatectomy.

OP-127

First Clinical Experience with Ultra-High Resolution Multi-Focal Collimators for Tc-99m-PSMA Imaging

C. Schmidkonz[1], C. Hollweg[1], J. Sanders[1], M. Beck[1], D. Schmidt[1], H. Vija[2], T. Kuwert[1], P. Ritt[1]; [1]Universitätsklinikum Erlangen, Erlangen, GERMANY, [2]Siemens Medical Solutions, Hoffman Estates, IL, UNITED STATES OF AMERICA.

Introduction: Radiopharmaceuticals based on the prostate specific membrane antigen (PSMA), such as Tc-99m-MIP-1404 (Progenics Pharmaceuticals Inc., New York, NY), are used for for diagnosing and staging prostate cancer, and their broader application will most likely lead to a substantial increase in patients undergoing respective SPECT/CT exams. In order to keep the associated radiation burden for patients and medical personal as low as reasonably achievable and provide the required increased throughput, reductions in radiopharmaceutical dose and SPECT acquisition time are desirable. The prototype Siemens Ultra-High Resolution SMARTZOOM (UHRSZ) Collimator uses an astigmatic array of boreholes to offer an increase in photon sensitivity compared to the low-energy high-resolution (LEHR) collimator. The sensitivity depends on the source-detector distance and at 28cm, is at least 210 cps/MBq, compared to roughly 91 cps/MBq for LEHR. The UHRSZ features increased spatial resolution (<6 mm geometric resolution @10 cm distance) over the known SMARTZOOM collimator, which is designed for cardiac imaging. We present our first experience with the UHRSZ collimator in 15 patients with prostate cancer. **Methods:** In 15 patients, SPECT/CT of the thorax and lower abdomen was performed 2-4 h p.i. of 654.9±68.4 MBq Tc-99m-MIP-1404 using both LEHR and UHRSZ collimators. The SPECT acquisition time was 15 min for all scans. The average time difference between acquisitions was 39±14 min. Two experienced readers independently evaluated the reconstructed SPECT datasets for MIP-1404 positive lesions and the occurrence of imaging artifacts (e.g. streaks, excessive noise, and geometric distortions). Additionally, the number of photon counts for each lesion was determined from the SPECT projection data. **Results:** In 12 out of 15 patients, a total of 18 tracer positive lesions were detected (see Figure 1 for a representative example). These were located in lymph nodes (n=5), prostate (n=9), and skeleton (n=4). Agreement between images of both collimators was excellent, with 18/18 lesions detected in LEHR and UHRSZ respectively. No divergent lesions were found. Inter-reader agreement was high, with both readers identifying the same number and location or absence of lesions. No imaging artifacts were observed. The lesions' photon count levels were, on average, 67% (range 11-133%) higher for the UHRSZ acquisition, compared to the LEHR-SPECT. **Conclusion:** For diagnosing PSMA-positive lesions, UHRSZ collimators showed excellent agreement with the standard LEHR-SPECT while providing increased photon count levels, which could be used for e.g. decreasing the SPECT acquisition time or injected activity.

Aim: This study investigates the naturalistic impact of florbetaben positron-emission tomography (PET) on diagnosis and management of mildly demented patients for whom the etiological diagnosis remains uncertain despite an exhaustive expert work-up. **Material and Methods:** This multicentre open label study was performed at French tertiary memory clinics in patients presenting with most complex clinical situations (ie, early-onset, atypical clinical profiles, suspected mixed etiological conditions, unexpected rate of progression), for whom cerebrospinal fluid (CSF) analysis was indicated but either not feasible, or considered as non-contributory (ie, uninterpretable due to technical problems, values close to threshold, only one or two abnormal biomarkers out of three, or result not consistent with clinical information). Therefore, this clinical trial was designed to demonstrate the potential impact of amyloid PET without interfering with the current standard practices of expert centres (ClinicalTrials.gov: NCT02681172). Following an ini-tial diagnosis, florbetaben PET was performed, and a confirmed or revised diagnosis was provided after result disclosure. PET images were visually assessed in each center by readers who had undergone appropriate training. Changes in diagnosis, diagnostic confidence and patient management after PET result disclosure were analyzed. **Results:** 205 patients (70.9±9.7 years) were enrolled with evaluable PET scans; of these, 87 had a prior lumbar puncture (42.4%). 64.4% of scans (132/205) were amyloid-positive. Scan results led to changed diagnosis in 66.8% of cases (137/205), particularly for negative scans (83.6% vs 57.6% of positive scans; p<0.0001). Improved diagnostic confidence was reported in 81.5% of cases (167/205; p<0.0001), with an overall improvement of 30.2%, leading to a confidence of 82.6% after PET disclosure. Changes in management were reported for 80.0% of patients (164/205), and considered as substantial in 50.7% (104/205) of patients (any change in initiation or withdrawal of medication, additional diagnostic tests, or referral to a new specialist). Initiation of new medication was mainly reported following amyloid-positive PET scans, whereas withdrawal of medication was exclusively reported for amyloid-negative PET scans. Results were similar regardless of patients' eligibility criteria. **Conclusions:** The results demonstrate that florbetaben PET improves diagnostic and patient management parameters when a biomarker of amyloid pathology is necessary for differential diagnosis but CSF is not helping because its results are inconclusive, or lumbar puncture is contraindicated or refused. In the context of the existing healthcare framework, high level improvement and immediate clinical utility are thus provided by selective implementation of florbetaben PET into current standard practices for the most complex dementia cases.

OP-129

Impact of 18F-Florbetaben PET on Differential Diagnosis of Unclear Clinical Routine Cases

M. Brendel[1], J. Schnabel[1], S. Schönecker[1], E. Brendel[1], J. Meyer-Wilmes[1], C. Catak[1], O. Pogarell[1], J. Levin[1], A. Schildan[2], M. Patt[2], P. Bartenstein[1], O. Sabri[2], H. Barthel[2], A. Danek[1], K. Bürger[1], A. Rominger[1]; [1]University of Munich, Munich, GERMANY, [2]University of Leipzig, Leipzig, GERMANY.

Aim: In recent years several 18-F-labelled amyloid PET tracers have been developed and obtained clinical approval. Despite widespread use in scientific investigations, studies in clinical routine settings are still limited. Therefore, we investigated the impact of 18-F-florbetaben (FBB)-PET in patients with clinical suspicion of dementia and unclear presentation after 18-F-fluordesoxyglucose (FDG)-PET. **Material and Methods:** All subjects were referred with clinical suspicion of dementia due to neurodegenerative disease from the departments of neurology and psychiatry. After undergoing an FDG-PET, patients were discussed in the interdisciplinary dementia board where an additional FBB-PET was recommended due to uncertainty on the final diagnosis. The most likely diagnosis as well as potential differential diagnoses before the FBB-PET were documented. 90-110 min p.i. recordings of FBB were interpreted visually and classified as amyloid-positive or -negative. Clinical diagnoses were

compared before and after FBB-PET. **Results:** A total of 107 patients (age 69.4 ± 9.7y) were included in the study, 65 were visually rated amyloid-positive, 42 amyloid-negative. In 83% of all former unclear cases a final clinical diagnosis could be reached after FBB-PET. FBB-PET changed the most likely prior diagnosis in 28% of all cases. The highest impact on the change of the most likely diagnosis was observed for distinguishing Alzheimer's dementia (AD) from fronto-temporal dementia (FTLD), where FBB-PET resulted in a change of the most likely prior diagnosis in 41%. **Conclusion:** FBB-PET has a high additive value in establishing the final clinical diagnosis in cases with suspected dementia when FDG-PET remains inconclusive. The differentiation between AD and FTLD resulted in the most frequent change in diagnosis and should therefore primarily be solved by amyloid-PET. A considerable impact on patient management can be supposed, especially in light of upcoming disease specific therapies.

OP-130

Reshaping the amyloid buildup curve in Alzheimer's disease? - Partial volume effect correction of longitudinal amyloid PET data

M. Rullmann, O. Sabri, H. Barthel; University of Leipzig, Department of Nuclear Medicine, Leipzig, GERMANY.

Aim: In Alzheimer's disease (AD), it is believed by many researchers that brain β-amyloid load buildup over time reaches a plateau at an early symptomatic disease stage. In the "hot-spot" imaging technique of amyloid PET, brain atrophy-related partial volume effects (PVEs) negatively impact the image signal. This cross-sectional ADNI data analysis project aimed at testing the shape of the amyloid buildup curve in AD after correcting the PET data for PVEs. **Methods:** We obtained ADNI data of 216 subjects (17 with AD dementia: 76±6 years, 8 females, 22.4±2 MMSE; 122 with early MCI: 71±8 years, 48 females, 28.3±2 MMSE; 77 with late MCI: 71±8 years, 36 females, 27.5±2 MMSE) in whom 18F-florbetapir PET, MRI (both acquisitions within ±50 days) and MMSE scoring data were available in follow-up with at least two PET visits. PVE correction of the PET data was performed in PVELab using the modified Müller-Gärtner method. Using the PVELab atlas, regional SUVRs were obtained with and without PVE correction using cerebellar cortex as reference region. Additionally, composite SUVRs were computed using the volume-weighted mean of frontal cortex, parietal cortex, occipital cortex, temporal cortex, anterior and posterior cingulate cortex. A composite SUVR threshold of 1.1 was applied to include amyloid-positive subjects only. **Results:** The PVE-corrected PET data revealed significantly higher regional and composite SUVR changes over time as compared to the non-corrected PET data (composite SUVRs: P = 0.0002). With decreasing MMSE scores, the slopes of the composite SUVR increases were significantly higher with vs. without PVEC (F = 7.1, P = 0.008). Composite SUVR changes over time were correlated to the baseline MMSE scores when the PET data were PVE-corrected (r = -0.11, P = 0.049), but not without PVEC (r = -0.07, P = 0.16). **Conclusion:** These cross-sectional PVE correction results of longitudinal amyloid PET data point to the amyloid buildup curve in AD potentially not reaching a plateau. A further prospective

evaluation of the impact of PVE correction on the in vivo characterization of time-dependent AD pathology is, thus, warranted.

OP-131

Improved Risk Stratification for Conversion from Mild Cognitive Impairment to Alzheimer's Disease with a multi-analytical Evaluation of [¹⁸F]-AV45 Amyloid PET

L. Wagner[1], M. Brendel[1], F. Scheiwein[1], A. Delker[1], J. Sauerbeck[1], P. Bartenstein[1], K. Ishii[2], C. Hosakawa[2], A. Rominger[1]; [1]Department of Nuclear Medicine, Ludwig-Maximilians-University of Munich, Muenchen, GERMANY, [2]Department of Radiology, Kinki University Osaka, Osaka, JAPAN.

Introduction: Amyloid positron-emission-tomography (PET) is used to evaluate the cerebral amyloid burden in patients with mild cognitive impairment (MCI). The most accurate interpretation in regards to conversion to Alzheimer's dementia (AD) is currently under investigation. **Subjects & Methods:** We analyzed [¹⁸F]-AV45-PET data of 396 subjects with MCI from the ADNI database. Patients had a clinical follow-up for at least two years after the initial PET-scan. Single volume-of-interest (VOI) values as well as a cortical composite VOI were generated and standard-uptake-value ratios (SUVR) were calculated using different reference regions such as cerebellar grey matter (CBL), brainstem (BST) or subcortical white matter (WM). Thresholds were obtained for each reference region by the best tradeoff between sensitivity and specificity. In addition, a visual read was performed. Receiver operating characteristics were calculated and expressed as area under the curve for the discriminatory power for conversion prediction within the observation period. Cox regression was performed for risk stratification of conversion from MCI to AD. **Results:** During the mean follow-up time of 45.6 months n = 110 converters to AD could be identified. Compared to subjects with negative results for the evaluated method, the composite VOI with WM reference showed best discriminatory power and conversion-risk stratification with a hazard ratio (HR) of 5.3. Other reference regions (HR$_{CBL}$ = 3.2; HR$_{BST}$ = 4.0) as well as the visual read (HR$_{visual}$ = 3.4) performed worse. The combination of all four methods further improved the risk stratification for conversion of MCI to AD, i.e. positivity of all four methods resulted in a HR of 12.5 compared to the absence of any positive item. Consequently, the conversion rate increased as a function of the amount of positive results, ranging between 5 to 67% within the observation period. Single region SUVR instead of the composite SUVR showed no further predictive value. **Conclusion:** Quantification using three different reference regions (CBL, BST and WM) plus the visual read showed the best conversion-risk stratification in subject with MCI according to [¹⁸F]-AV45-PET estimates. These encouraging results should be implemented in prospective clinical trials.

OP-132

Higher amyloid deposition in the striatum in familial Alzheimer's disease: a preliminary PET/CT and PET/MRI study

L. Fu, J. Zhang, B. Xu, J. Tian; Department of Nuclear Medicine, the Chinese PLA General Hospital,, Beijing, CHINA.

Purpose: It is assumed that the abnormal amyloid-β deposition is an initiating event in Alzheimer's disease (AD) and both typical and AD variants showed similar diffuse patterns of amyloid deposit as the positron emission tomography (PET) agent Pittsburgh compound-B (PIB) reflected. In the current study, we reviewed the PIB-PET images of familial AD (FAD), sporadic AD (SAD) and cognitively normal elder controls (NC) to find whether there is a different amyloid deposit pattern among groups. **Methods and Materials:** Retrospective analysis of the ^{11}C-PIB PET/CT or PET/MRI images of 5 FAD patients (Male/Femal:1/4, age range: 36-43 Yr, 39.0 ± 3.4), 10 SAD patients (Male/Femal:4/6, age range:55-68 Yr, 59.9 ± 4.0) and 10 NC subjects (Male/Female:6/4, age range:56-65 Yr, 60.4 ± 3.2) with definite clinical diagnosis and complete neuropsychological tests (such as Mini-Mental State Examination, MMSE). **PIB-PT acquisition:** All subjects received ^{11}C-PIB injection intravenously (4.44-5.55MBq/kg) 40-min prior to data acquisition, including 3 of FAD at a PET/CT (Biograph 64, SIEMENS, Germany) and 22 subjects at a PET/MRI scanner (Biograph mMR, SIEMENS, Germany). **Data analysis:** Regions of interest were drawn over cortex, the striatum and cerebellar gray matter (CGM) in CT or MRI images and their corresponding CT/MRI based attenuation corrected PIB-PET images manually. The CGM was chosen as reference region for standardized uptake value ratio (SUVR) measurement. One-way ANOVA analysis was used to assess the differences of ages, MMSE scores and SUVRs of cortical and striatum among 3 groups. **Results:** FAD patients were younger than SAD and NC subjects (F=70.02, P<0.05). Both the two AD groups' MMSE scores were significantly worse than NC (F=43.77, P<0.05). No obvious bran atrophy was detected on MRI images in 3 FAD patients. No significant difference in cortical 11C-PIB retention were observed between FAD and SAD patients, but were great higher than that of NC (F=50.61, P<0.01). Significant higher SUVR of striatum was observed in FAD than SAD and NC. In addition, the SUVR of striatum in SAD was also higher than NC (F=28.93, P < 0.01). **Conclusion:** FAD patients showed a special PIB distribution pattern including extensive striatal amyloid deposition, along with the typical cortical deposition, which might associated with their early-onset cognitive decline.

OP-133

[18F]Florbetapir PET/CT to assess the cerebral ß-amyloid binding in Parkinson's Disease Dementia - does the striatum still a key player?

M. Gennaro[1], G. Aghakhanyan[1], S. Mazzarri[1], G. Puccini[1], G. Palermo[2], D. Frosini[2], G. Manca[1], L. Antonacci[1], S. Muccioli[1], L. Fantechi[1], I. Paglianiti[1], R. Ceravolo[2], U. Bonuccelli[2], D. Volterrani[1]; [1]Regional Center of Nuclear Medicine, University Hospital of Pisa, Pisa, ITALY, [2]Unit of Neurology, Department of Clinical and Experimental Medicine, University of Pisa, Pisa, ITALY.

Aim: Cognitive impairment is a common non motor complication of Parkinson's Disease (PD), which increases in severity and frequency over time. The patients with PD are 4-6 times more likely to develop dementia (PDD) than age-matched controls. The growing evidence indicates a possible synergistic role of

Alzheimer type brain lesions containing ß-amyloid (Aß) and tau proteins with progressive cognitive decline in PD. Moreover, the recent neuropathological studies have shown that striatal Aß deposition is significantly greater in PDD patients, thus, suggesting that both cortical and also striatal Aß has pathophysiological impact in PDD. The aim of our study was to compare regional-selective cortical and subcortical amyloid burden in PDD patients in comparison to cognitively normal elder individuals. **Materials and Methods:** Fourteen consecutive PDD patients (mean age 72.1 ± 3.9; Mini-Mental State Examination, MMSE 21.1 ± 1.3) referred to our centre and six cognitively and clinically normal control subjects (mean age 72 ± 1.6; MMSE 28.8 ± 1.2) were recruited. The demographic and PD/PDD-related clinical variables (age of onset, disease duration, dementia onset, dementia duration) were collected. All subjects underwent a 20-min [18F]Florbetapir PET/CT study, acquired 50 min after intravenous injection of 370 MBq [18F]Florbetapir. The images were spatially normalized using the AV45 PET template in MNI brain atlas space (Avid Radiopharmaceuticals) and voxel-wise standardized uptake value ratio (SUVR) images were calculated using the whole cerebellum as a reference region. Subsequently, a mean SUVR was extracted from the 6 regions (cerebral cortex, cerebral white matter, precuneus, thalamus, caudate and putamen) by creating anatomical volume of interests (VOIs) in FMRIB Software Library v.5 (FSL) using Harvard-Oxford cortical/subcortical atlas. **Results** Three out of fourteen patients (21.4%) demonstrated a positive amyloid-scan after visual inspection and qualitative reading. We revealed no significant correlation between MMSE scores, clinical variables and mean SUVRs in the PDD patients. Between group analysis showed significantly higher [18F]Florbetapir retention in the putamen in PDD group compared to controls (p < 0.01). The group difference remains statistically significant after adjusting for age and further excluding the [18F]Florbetapir amyloid-positive scans. **Conclusion:** Our preliminary data confirm previous postmortem evidence showing an elevated putaminal Aß deposition in PDD patients, thus, suggesting that increased amyloid burden in the putamen may be involved in the pathophysiology of PDD. Additional large cohort studies will be required to elucidate whether increased amyloid load in the putamen contribute to cognitive decline in PDD patients.

OP-134

A Pilot Study on Hybrid 18F-Florbetaben PET/MRI in Patients with White Matter Diseases

M. Rullmann[1], S. Haars[2], P. Werner[1], R. Schmidt[2], J. Orthgieß[2], S. Tiepolt[1], M. Patt[1], D. Lobsien[3], K. Hoffmann[3], O. Sabri[1], H. Barthel[1], F. Then Bergh[2]; [1]University of Leipzig, Department of Nuclear Medicine, Leipzig, GERMANY, [2]University of Leipzig, Department of Neurology, Leipzig, GERMANY, [3]University of Leipzig, Department of Neuroradiology, Leipzig, GERMANY.

Background: PET amyloid imaging with tracers like [18F]Florbetaben allows the in vivo visualization of cortical β amyloid (Aβ) depositions as occurring in Alzheimer's disease. [18F]Florbetaben also - independent from Aβ - binds to myelin in the

brain white matter (WM). This led to the idea of employing this tracer to image multiple sclerosis, with promising preliminary results. Further studies in other WM diseases are currently missing. **Aim:** We aimed at quantifying the [^{18}F]Florbetaben in vivo uptake in patients with different WM diseases in comparison to non-WM diseased controls. By that, we hypothesized a decreased WM tracer accumulation in the patient group as a correlate of demyelinisation. **Methods:** We examined 13 patients with different WM diseases (multiple sclerosis [n=4]; progressive multifocal leukoencephalopathy [PML, n=3]; adult-onset leukodystrophy [ADLD n=3]; cerebral autosomal dominant arteriopathy with subcortical infarcts and leukoencephalopathy [CADASIL, n=3]) and concurrent mild cognitive impairment using [^{18}F]Florbetaben PET/MRI. 13 age- and gender-matched patients with cognitive impairment but without WM disease served as controls. The PET data were acquired 90-110min p.i. using a simultaneous PET/MR system (Biograph mMR, Siemens) after administering ~300MBq [^{18}F]Florbetaben. Simultaneous MR acquisition included T1 MPRAGE 3D with and without i.v. gadolinium and T2 FLAIR 3D. Segmentation of WM and generation of standard volumes of interests (AAL) was done in PMOD 3.5. WM lesions were segmented by the lesion prediction algorithm as implemented in the LST toolbox for SPM. We determined the WM SUV ratio (SUVR$_{WM}$) using the cerebellar cortex as reference region. For the WM disease patients, we additionally calculated the WM lesion SUVR (SUVR$_{WML}$) using the same reference. **Results:** In the patients, the SUVRs$_{WM}$ were significant lower as compared to the controls (1.78±0.32 vs.1.90±0.14, p=0.04). Within the patient group, WM lesions showed an even lower tracer retention compared to the WM uptake (SUVR$_{WML}$ vs. SUVR$_{WM}$: 0.98±0.22 vs. 1.78±0.32, p<0.001). These WM data were independent of the cortical tracer uptake. An additional subgroup analysis regarding WM uptake degree and distribution vs. WM disease is planned after recruitment of a larger cohort. **Conclusion:** Patients with different WM diseases show decreased [^{18}F]Florbetaben WM binding, especially in WM lesions, compared to non-WM-diseased controls. Further research using larger cohorts and including other MR parameters is justified to investigate the potential of [^{18}F]Florbetaben PET/MRI in diagnosing demyelinating diseases.

OP-135

Human Whole-body Biodistribution and Radiation Dosimetry of [^{18}F]PF-06684511, a Novel Radioligand for Brain Imaging of Beta-secretase

A. Varrone[1], R. Arakawa[1], A. Takano[1], S. Nag[1], V. Stepanov[1], P. Stenkrona[1], P. Grybäck[2], M. Bolin[2], L. Chen[3], L. Zhang[3], P. He[3], A. Villalobos[4], T. McCarthy[3], C. Halldin[1]; [1]Department of Clinical Neuroscience, Centre for Psychiatry Research, Karolinska Institutet and Stockholm County Council, Stockholm, SWEDEN, [2]Karolinska University Hospital, Medical Radiation Physics and Nuclear Medicine, Stockholm, SWEDEN, [3]Worldwide Research & Development, Pfizer Inc., Cambridge, MA, UNITED STATES OF AMERICA, [4]Worldwide Research & Development, Pfizer Inc., Groton, CT, UNITED STATES OF AMERICA.

Beta secretase (BACE) is a brain enzyme implicated in the pathophysiology of amyloid-beta (Aβ) accumulation in Alzheimer´s disease (AD). BACE inhibitors are currently under development as drugs for the prevention or treatment of AD. An imaging approach to quantify the brain BACE level would add great value to the development of inhibitors of Aβ production with regard to the selection of high-risk population and to the improvement of therapeutic outcome. The radioligand [^{18}F]PF-06684511 has been developed for in vivo imaging and quantification of BACE using positron emission tomography (PET). The aim of this study was to calculate the radiation dose from the administration of [^{18}F]PF-06684511, based on human whole-body PET/CT scans. **Methods:** Four PET/CT sessions (0-54 min; 90-144 min; 210-264 min; 330-366 min) were performed using a GE Discovery PET/CT 710 Clarity Edition for 6 hr after the injection of 111±13 MBq of [^{18}F]PF-06684511 (specific radioactivity: 42±10 GBq/μmol; injected mass: 1.2±0.3 μg) in 5 healthy subjects (2M/3F 48±5 y). Regions of interest were delineated on coronal images to calculate the percent injected dose (%ID). Urine was collected during the breaks between PET/CT sessions and the radioactivity in the urine was measured with the PET/CT system. Estimates of the absorbed radiation dose were calculated with the OLINDA/EXM software using the male adult model. **Results:** Peak uptake values were highest for the liver (25.2±2.3 %ID at 0.5 hr) and lungs (12±3 %ID at 0.2 hr), followed by the small bowel (11.8±2.9 %ID at 5.8 hr), brain (3.5±0.6 %ID at 0.4 hr), stomach (2.6±1.0 %ID at 2.2 hr), heart (2.5±0.5 %ID at 0.2 hr), pancreas and kidneys (2.3±0.7 %ID and 2.2±1.0 %ID at 0.2 hr). Up to 10±4 %ID was eliminated with the urine at 6 h. The organ receiving the largest dose was the pancreas (0.093±0.052 mSv/MBq), followed by the liver (0.071±0.006 mSv/MBq), the gall bladder and urinary bladder wall (0.058±0.041 and 0.058±0.021 mSv/MBq), and the ULI wall (0.051±0.011 mSv/MBq). The calculated effective dose was 0.025±0.001 mSv/MBq. **Conclusion:** The estimated radiation burden of [^{18}F]PF-06684511 was similar to [^{18}F]FDG (0.019 mSv/MBq) and ^{18}F-labelled radioligands used for Aβ imaging in AD ([^{18}F]AV-45: 0.019±0.004 mSv/MBq; [^{18}F]BAY94-9172: 0.015±0.001 mSv/MBq; [^{18}F]GE067: 0.034±0.003 mSv/MBq). Based on the calculated effective dose of [^{18}F]PF-06684511, the administration of 400 MBq corresponds to a radiation dose of 10 mSv, suggesting that [^{18}F]PF-06684511 can be used in clinical trials to measure the brain BACE level and/or the occupancy by BACE inhibitors in AD.

OP-136

The impact of Lung Perfusion Scintigraphy in the emergency management of patients with suspected Pulmonary Embolism

C. Ferrari, A. Niccoli Asabella, A. Cimino, G. Bianco, M. Fanelli, E. P. Mossa, A. Di Palo, G. Rubini; Nuclear Medicine Unit, AOU Policlinic of Bari, University of Bari, bari, ITALY.

Aim: The aim of our study was to highlight the role of Lung Perfusion Scintigraphy (LPS) in the management of patients with suspected pulmonary embolism (PE) admitted as urgent and in the "on-call" 24hrs service. **Materials and Methods**: We retrospectively revised 2166 LPS performed for PE suspicion (years 2012-2016). The relation between LPS and symptoms, risk factors (i.e. arythmia, drugs, surgery, thrauma, deep venous thrombosis), D-dimers dosage and other diagnostic imaging examination (Chest X-ray and/or Computed Tomography (CT)) were evaluated by contingency tables and Odds Ratio (OR). **Results**: 1730/2166 (79.8%) were urgent and admitted as emergency; 1026/1730 (59.3%) were performed during the on-call 24hrs service. The request of LPS came from emergency-room in 981/1730 (56.7%) patients, pneumology in 187/1730 (10.8%), neurology in 83/1730 (4.8%), internal medicine in 112/1730 (6.5%), surgery in 90/1730 (5.2%), cardiology in 57/1730 (3.3%), and other departments in 220/1730 (12.7%). LSP resulted positive for PE and treated in 294/1730 (17%) patients, while negative in 1436/1730 (83%). The presenting symptoms, single or differently associated, were chest pain in 536/1730 (31%), dyspnea in 900/1730 (52%), cough in 225/1730 (13%) and none in 69/1730 (4%); only the presence of dyspnea was significantly related to the presence of PE (OR=1.596 p=0.003); chest pain and cough were not related to PE (p> 0.005). Risk factors were present in 960/1730 (55.5%) patients and none of them were related to PE detected by LPS (p> 0.005). D-dimer dosage was increased in 1678/1730 (97%) patients and were not related to PE detected by LPS (p> 0.005). A previous diagnostic exam was performed in 1306/1730 (75.5%) patients. The Chest X-ray and/or CT resulted negative in 332/1306 (25.4%), suspected for PE in 319/1306 (24.4%), non-specific with pleural effusion in 245/1306 (18.8%) and non-specific with inflammatory interstitial diseases in 410/1306 (31.4%). LPS resulted positive for PE in 46/332 (13.8%) with negative Chest X-ray and/or CT, in 75/319 (23.4%) with suspected PE, in 37/245 (15.2%) with pleural effusion and in 60/410 (14.7%) with inflammatory interstitial diseases. The relation between LPS and other imaging resulted statistically significant ($\chi 2$=17.5 p=0.001). **Conclusions**: LPS has a key role in the assessment of PE, optimizing the management of patients who do not require admission to intensive care unit avoiding high costs and overcrowded hospitalization. Our data support the need of LPS performed as emergency in on-call 24hrs service in each metropolitan area.

OP-137

The Prognostic Significance Of Abnormal Lung Perfusion In Patients With Idiopathic Pulmonary Arterial Hypertension

L. Wang, R. Ma, D. Wu, W. Fang; Chinese Academy of Medical Science & Fu Wai Hospital, Beijing, CHINA.

Purpose: A ventilation-perfusion lung scan is recommended to be performed for patients with pulmonary hypertension, which is mainly used to exclude the diagnosis of chronic thromboembolic pulmonary hypertension according to the absence of mismatched perfusion defects. Although without this typical sign of pulmonary embolism, patients with idiopathic pulmonary arterial hypertension (IPAH) may present abnormal lung perfusion. However, evidences on the prognostic value of the presence of abnormal pattchy pattern of lung perfusion for IPAH patients are lacking. In this study, we aimed to study the abnormalities of lung perfusion to identify its prognostic value in patients with IPAH. **Methods:** Clinical database of consecutive patients with pulmonary hypertension who underwent lung ventilation-perfusion scans were reviewed. Patients diagnosed with IPAH according to current guidelines for the diagnosis and treatment of pulmonary hypertension were included in this study. Images of lung perfusion scans were analysed and categorised as patchy or normal pattern by independent experienced nuclear physicians. The relation of lung perfusion defects with patients' survival was analysed. **Results:** A total of 328 IPAH patients were enrolled. During a median follow-up period of 870 days, 14 patients were lost to follow-up. 52 patients reached the primary end-point of all-cause mortality. Of the 328 patients, 141 (43%) patients exhibited normal lung perfusion, while the other 187 (57%) patients had patchy abnormal lung perfusion. On univariate Cox analysis, the presence of patchy pattern were significantly associated with the overall survival (hazard ratio [HR]) 2.63, 95% confidence interval [CI] 1.38-5.02, p=0.003). Patients with patchy pattern had a worse outcome (patchy pattern vs normal perfusion, log-rank 9.343,p=0.009). On multivariate Cox proportional hazard analysis, the presence of patchy pattern remained a significant independent predictor of the endpoint (HR 2.42, 95%CI 1.26-4.64, p=0.008). The other significant independent covariates were mean pulmonary artery pressure, NT-pro BNP and NYHA (class III and IV). **Conclusions:** In patients with IPAH, abnormal lung perfusion largely existed and was significantly correlated with worse outcome. In the diagnostic algorithm of pulmonary hypertension, beyond exclusion of chronic thromboembolic, perfusion lung scan may be of importance to identify IPAH patients at risk of all-cause mortality.

OP-138

Assessment Of Lung Glucose Uptake In Patients With Systemic Erythematous Pulmonary Arterial Hypertension: A Quantitative FDG PET Imaging Study

L. Wang[1], Q. Wang[2], L. Zhao[3], X. Zeng[2], W. Fang[1]; [1]Chinese Academy of Medical Science & Fu Wai Hospital, Beijing, CHINA, [2]Peking Union Medical College Hospital, Beijing, CHINA, [3]Imperial College London, London, UNITED KINGDOM.

Purpose: Pulmonary arterial hypertension associated with systemic lupus erythematosus (SLE-PAH) has not been well studied. Measures for tracking pulmonary vascular disease directly in SLE-PAH patients are lacking. Enhanced glycolysis in the lung of idiopathic PAH (IPAH) patients measured by positron emission tomography imaging with fluorine-18-labeled 2-fluoro-2-deoxyglucose (FDG-PET) has been shown to correlate to pulmonary vascular remodeling. Herein we explored the potential role of FDG-PET imaging in SLE-PAH patients and aimed to investigate the relationship between the lung glucose uptake and SLE-PAH disease activity. **Methods:** Sixty-minute dynamic FDG-PET was

for the first time applied to 14 SLE-PAH patients, 20 IPAH patients and 10 healthy volunteers. Patlak analysis was used to quantify lung FDG uptake (influx rate Ki). **Results:** Lung FDG uptake in SLE-PAH patients (Ki: 0.00714 ± 0.000602 ml/g/min) was significantly increased compared to that in healthy volunteers (Ki: 0.000262 ± 0.000168 ml/g/min) (P<0.05). SLE-PAH patients with active disease (SLE disease activity score SLEDAI≥5) (Ki: 0.001075 ± 0.00055 ml/g/min) demonstrated significantly higher lung FDG uptake than those with quiescent disease (SLE-DAI<5) (Ki:0.000233 ± 0.00017 ml/g/min) (P=0.0038) and IPAH (Ki: 0.000524 ± 0.000314 ml/g/min) (P=0.0025). Lung FDG uptake in SLE-PAH significantly correlated with SLEDAI score and plasma level of complement C3 and C4 (Ki vs SLEDAI, r=0.607, p=0.021; Ki vs C3, r=-0.568, p=0.034; Ki vs C4, r=-0.661, p=0.010), suggesting patients with higher lung FDG uptake tended to have more active disease and more activated complement system consuming more C3 and C4. **Conclusions:** Lung FDG uptake significantly increased in SLE-PAH and correlated with SLE disease activity. Our data support the hypothesis that FDG lung uptake is associated with the lung inflammatory pathology in PAH. FDG-PET imaging may be developed as a potential intrapulmonary activity marker for patients with SLE-PAH.

OP-139

Comparative analysis of regional lung perfusion measurements using radiolabeled microspheres and PET/CT and fluorescence-labeled microspheres in an experimental, anesthesiological study of acute lung injury in pigs

A. Braune, A. Gueldner, J. Kotzerke, M. Gama de Abreu; University Hospital Carl Gustav Carus at the Technische Universität Dresden, Dresden, GERMANY.

Aim: Both in healthy lungs and in lungs exposed to experimental acute respiratory distress syndrome (ARDS) it has been shown that measurements of the distribution of pulmonary blood flow (PBF) determined using radiolabeled microspheres and non-radioactive, fluorescence-labeled microspheres correlate well [Glenny et al., JApplPhysiol.1993 May;74(5):2585-97; Hübler et al.: JApplPhysiol.1999 Dec;87(6):2381-5]. However, such comparisons have so far only been done for ex-vivo measurements of PBF. In this study we compared in-vivo measurements of the distribution of PBF using radiolabeled microspheres and PET/CT with ex-vivo measurements using fluorescence-labeled microspheres. **Methods:** Details of the experimental protocol are given in [Güldner et al.: Anesthesiology.120(3):673-82]. Briefly, in 7 pigs ARDS was induced by saline lavage. PBF was marked by intravenous injection of fluorescence-labeled and radiolabeled microspheres (68Ga) after 1h of mechanical ventilation superposed with >60% of spontaneous breathing. The distribution of radiolabeled microspheres was assessed by PET, and lung weight was determined by CT. The distribution of fluorescence-labeled microspheres was assessed by ex-vivo sampling of lung pieces and measurements of emitted fluorescence intensities and tissue weights. For both measurements, PBF of the left and right lungs were analyzed separately by normal-

ization of the relative intensity of each voxel/lung piece to the whole lung intensity and to its weight and volume. PBF gradient was determined by linear least-squares regression of PBF and location along the ventro-dorsal axis and slopes of regression lines were compared between measurements. Also, outer lung dimensions assessed in-vivo and ex-vivo were compared. **Results:** The resolution of PBF measurements using radiolabeled microspheres (4.06 x 4.06 x 5 mm3) was about 21 times higher than those using fluorescence-labeled microspheres (12 x 12 x 12 mm3). Excitation and drying of the lungs caused an increase of their cranio-caudal expansions by 10.8%, whereas the ventro-dorsal and left-right expansions decreased by 14.4% and 13.1%, respectively. Both measurements revealed a significant difference of ventro-dorsal PBF gradients from zero and slopes were of comparable magnitude. **Conclusion:** In this model of ARDS in pigs, ex-vivo measurements of the distribution of fluorescence-labeled microspheres and in-vivo measurements of the distribution of radiolabeled microspheres revealed comparable results in respect to the presence and magnitudes of ventro-dorsal PBF gradients. Consequently, fluorescence-labeled microspheres and radiolabeled microspheres can be used interchangeably for the determinations of PBF gradients, despite a much lower resolution of the ex-vivo measurement and the occurrence of lung deformation induced by lung extraction and drying.

OP-140

A novel, simple equation improving the accuracy of glomerular filtration rate (GFR) measurement from two blood samples

G. Arsos[1], E. Moralidis[1], D. Katsampoukas[1], E. Manou[2], C. Sachpekidis[3]; [1]3rd Department of Nuclear Medicine, Medical School, Aristotle University of Thessaloniki, Papageorgiou General Hospital, Thessaloniki, GREECE, [2]Nephrology Department, Papageorgiou General Hospital, Thessaloniki, GREECE, [3]Institute of Nuclear Medicine, Bern University Hospital, Bern, SWITZERLAND.

Aim: Glomerular filtration rate (GFR) measured by exogenous tracer plasma clearance using multiple blood samples (GFRMS) is currently the gold standard for renal function assessment. Measurement by the slope-intercept technique, limiting the number of samples at two (GFR2), is a very convenient alternative for routine clinical use. However, as it systematically overestimates GFR, proper GFR2 correction becomes mandatory. All corrective formulas proposed are only moderately satisfactory and the most widely applied Brochner-Mortensen (BM) quadratic correction underestimates considerably higher GFR values. The aim of the present study is to derive a novel equation for optimum approximation of GFRMS by GFR2. **Materials and methods:** GFR was measured for clinical purposes in 1104 adult Caucasian patients by bolus i.v. injection of ^{51}Cr-EDTA, and plasma elimination analysis by two-compartment modelling of 10 blood samples obtained between 5 and 240 min p.i., (GFR10, in ml/min). Only 721 of them with almost perfect data fit ($r^2\geq0.995$) to the biexponential model were selected for further analysis. GFR2 was calculated from blood samples at 120 and 240 min

p.i and corrected by the BM formula (GFR2BM), both in ml/min. Patients were randomized into a derivation (DG, n=376) and a validation (VG, n=345) group. A new, power function equation (NE) correlating GFR2 with GFR10 values was developed by non-linear regression analysis of DG data and its performance was evaluated in the VG. The resulting GFR2NE values in the VG were compared with GFR10 as were the GFR2BM values. Significance was accepted for p<0.05. **Results:** GFR10 in all the 721 patients was 77±36 (range 10 - 216) ml/min. DG and VG did not differ in any demographic or renal function parameter. NE was formulated as $GFR10 = 1.587 \times GFR2^{0.887}$ ($r^2 = 0.981$) and was then tested in the VG. GFR2NE showed an excellent correlation with GFR10 values ($r^2 = 0.981$). The mean difference (bias) GFR10-GFR2NE and GFR10-GFR2BM was 0.2 (ns) and 7.2 (p<0.05) with 95% confidence intervals of agreement -8.9 to 9.4 and -4.4 to 18.8 ml/min respectively. **Conclusions:** The newly developed power function equation provides corrected GFR values derived from the two samples measurement very close to the results of the multisampling full kinetic analysis and performs better than the widely applied BM correction equation in a wide range of renal function in adult patients.

OP-141

Contribution Of Isotopic Renogram And SPECT-CT In The Diagnosis Of The Complications Of The Renal Transplantation

J. Gómez Hidalgo, A. Cobo Rodríguez, A. Sainz-Esteban, C. Gamazo Laherran, M. Alonso Rodríguez, M. Ruiz Gómez, M. González Selma, R. Ruano Pérez; Hospital Clínico Universitario de Valladolid, Valladolid, SPAIN.

Objective: to evaluate the contribution of the isotopic renogram in patients with kidney transplant, and the contribution of SPECT-CT. **Material and Method:** we included 283 patients who were operated on renal cadaver transplantation from January 2011 to December 2016. At 24 hours after transplantation, after administration of 370 MBq of 99mTc-DTPA, we performed a 30 minute renogram study focusing on the abdomen in anterior projection, followed by planar images at 30 and 180 minutes. Ten patients were performed an abdominal SPECT-CT after 180 minutes image. The findings were correlated with radiological studies and clinical-analytical. **Results:** Of the 283 patients (age: 58.0 +/- 12.8, 184 men and 99 women), 69 (24.4%) presented a normal study. In 33 (11.6%) were detected surgical complications: 14 renal artery / vein thrombosis; 5 infarcts; 6 ectasias or ureteral obstructions; 1 urinoma (confirmed with SPECT-CT); and 7 urinary leaks (4 confirmed with SPECT-TC). 13 patients were operated by transplantectomy, 4 presented renal function deterioration and 1 acute rejection. In 180 patients (63.6%), there was an evidence of ischemic alteration or an acute tubular necrosis (NTA): mild in 103 (57.2%); moderate in 52 (28.9%); and severe in 25 (13.9%). Evolutionarily, 2 (1.9%) cases with mild NTA evolved to renal failure (without rejection); in moderate NTA 16 (30.7%) evolved to renal failure (2 acute rejection); and in severe NTA 11 cases (44.0%) evolved to renal failure (1 acute rejection and 4 thrombosis involving transplantectomy). A second con-trol was performed on 48 patients, normalizing the function in 15. **Conclusions:** the renogram in transplanted patients allows the detection of surgical and / or ischemic complications, facilitating the implantation of corrective measures at an early stage. SPECT-CT is especially useful in the diagnosis of urinary tract and urinary leakage, improving the assessment of its extent and location.

OP-142

The usefulness of advanced numerical parameters of kidney output in the analysis of Tc-DTPA diuresis renography

S. Beatovic[1], M. Radulovic[2], M. Jankovic[3], D. Sobic Saranovic[1], B. Ajdinovic[2], V. Artiko[1]; [1]University of Belgrade Faculty of Medicine, Center for Nuclear Medicine, Clinical Center of Serbia, Belgrade, SERBIA, [2]Institute for Nuclear Medicine Military Medical Academy, Belgrade, SERBIA, [3]University of Belgrade Faculty of Electrical Engineering, Belgrade, SERBIA.

Purpose: The aims of this study were to calculate, by means of the International Atomic Energy Agency (IAEA) software, the values of Tc-99m DTPA diuretic renogram parameters in normal kidneys, hypotonic kidneys with good drainage after furosemide and kidneys with poor response to diuretic, b) to validate the accuracy of obtained parameters by comparing with the values published by other authors and c) to assess their diagnostic utility in distinguishing poor response to diuretic from good one. **Subjects and Methods:** 146 patients (mean age: 51.1 years) with evidence of poor washout through kidney outlet were investigated. 40-minutes acquisition with 240 10-sec images was applied. Furosemide was administered after 20min (F+20). Post-void static image was acquired at 50min. Two observers analyzed each study and classified kidneys into four categories. Group A consisted of 65 normal kidneys, contralateral to affected one, without any structural or functional anomaly on previous diagnostics; group B: 124 hypotonic kidneys with complete washout after furosemide; group C: 55 kidneys with poor response to diuretic; group D: 48 kidneys with indeterminate response after diuretic. Parameters analyzed were: T_{max}, $T_{1/2}$, output efficiency at 20min (OE_{20}), output efficiency at 40min (20min after furosemide injection, OE_{F+20}), normalized residual activity at 20min ($NORA_{20}$) and normalized residual activity on post-micturition acquisition ($NORA_{PM}$). **Results** were presented as mean±SD. For group 1 they were: T_{max}: 4.2±1.0 min; $T_{1/2}$: 14.5±2.4 min; OE20: 88±5%; OE_{F+20}: 95±4%, $NORA_{20}$: 0.70±0.23; $NORA_{PM}$: 0.07±0.03. Results for group 2 were: OE_{20}: 76±10%; OE_{F+20}: 93±2%; $NORA_{20}$: 1.28±0.56; $NORA_{PM}$: 0.08±0.02. For group 3: OE_{20}: 62±12%; OE_{F+20}: 79±7%; $NORA_{20}$: 2.05±0.56; $NORA_{PM}$: 0.22±0.09. Linear regression analysis showed significant inverse linear correlation between $NORA_{20}$ and OE_{20} (r = -0.972; y = 100.4 -18.8x). ROC analysis revealed cutoff values of predicting obstruction at 82% and 0.145 for OE_{F+20} and $NORA_{PM}$, respectively. Among kidneys with equivocal findings, 32 showed OE_{F+20} and $NORA_{PM}$ values in "non-obstructive" range, in 13 kidneys both parameters were "obstructive", and in 3 kidneys, OE_{F+20} indicated

obstruction, but NORA$_{PM}$ converted the pattern into non-obstructive. **Conclusion**: The results provided evidence of excellent agreement of obtained results with previously reported values of the quantitative parameters of kidney washout. The parameters of software contribute to accurate diagnosis of obstruction and help to clarify indeterminate findings of diuretic renogram. Nuclear medicine section of IAEA should be encouraged to produce final version of the software and to release it through IAEA Web site.

OP-143

Background Subtraction in Dynamic Renal Scintigraphy Revisited

M. Samal[1], V. Ptacnik[2], H. Jiskrova[2], D. Skibova[2]; [1]Charles University, First Faculty of Medicine, Prague, CZECH REPUBLIC, [2]General University Hospital, Prague, CZECH REPUBLIC.

One of the sources of error in performing quantitative planar nuclear medicine studies is correction for the presence of background activity surrounding the area of interest. Subtracting "background" in dynamic renal scintigraphy still remains a challenge (Blaufox MD, EJNMMI 2016; 43:548-549). The aim of this study was to analyze differences in split renal function measured by integral (INT) and Patlak-Rutland plot (PRP) methods after subtracting "tissue" (perirenal), "vascular", and "both" backgrounds (TB, VB, TVB). Methods: The study was performed with data collected in public database www.dynamicrenalstudy.org including 107 adult patients with a wide range of renal function. Time-activity curves were extracted from manually defined ROIs of the heart, left and right kidneys, and automatically defined ROI of perirenal background. Missing kidneys were substituted by background area contralateral to the existing kidney. Both INT and PRP methods were applied in a fixed time interval between 1 - 2 minutes (6th to 12th 10s frames) and their results compared using Passing-Bablok regression and the mean absolute differences. Total renal function was estimated from the heart ROI curve extrapolated using gamma fit. Results: After subtracting the same type of background, INT and PRP provided identical or almost identical results with 95 % confidence intervals of individual differences well below 5 % considered as accuracy limit acceptable in clinical practice. Mean absolute difference between INT (after VB subtraction) and PRP (with implicit VB subtraction) was lower than 1 %. In comparison with no background subtraction, subtracting TB, VB and TVB resulted in mean absolute differences (with 95 % confidence interval of the mean) of 2.5 (2.1-3.0), 3.7 (3.0-4.4), and 4.6 (3.7-5.5) % in INT, and 1.1 (0.9-1.4), 0.0 (0.0-0.0), and 1.1 (0.9-1.4) % in PRP. Subtraction of VB affected split renal function more than subtraction of TB. In most comparisons, background subtraction produced individual differences inversely proportional to total renal function (weak kidneys were affected more than normal kidneys). Conclusions: Background subtraction is mandatory in INT method. Preferably both TB and VB should be subtracted to approximate PRP performance. In PRP with implicit VB subtraction, additional TB subtraction results in only a small change lower than 5 % not affecting clinical performance of the method. With PRP, no preliminary perirenal or other "tissue" background subtraction is thus necessary that also avoids uncertainty which part of background and which subtraction weight should be chosen. The study was supported by the Czech Science Foundation grant 303/07/0950.

Internal bremsstrahlung: a forgotten but significant effect in ⁹⁰Y SPECT and ⁹⁰Y PET imaging

S. Walrand[1], M. Hesse[2], R. Lhommel[2], J. Francois[2]; [1]Cliniques Saint-Luc, Brussels, BELGIUM, [2]Université Catholique de Louvain, Brussels, BELGIUM.

Aim: During beta decay a photon may also be emitted due to the interaction of the beta particle with the decayed nucleus. For ⁹⁰Y, this so-called internal bremsstrahlung (IB) has at 150 keV half the intensity of external bremsstrahlung (EB) in water, but supersedes it above 540 keV to become five times as higher than EB at 1500 keV (Cengiz & Almaz, Rad Phys Chem 2004). Although being above routine energy acquisition windows, these high energy x rays easily cross the collimator septa or detector shielding, and may be down scattered into the energy window. Currently, IB is not modelled in the ion source implemented in Geant4 (4.9 and 4.10), and seems unknown by most of the nuclear medicine physicists. This study investigated the impact of IB in ⁹⁰Y imaging. **Methods:** SPECT and PET imaging were simulated using Gate with photon sources modelling the EB of ⁹⁰Y and of ³²P in water, including or not their IB emission. A 1/2 inch-thick NaI SPECT camera equipped with a MEGP collimator and state of the art LSO and GSO PET systems were modelled. All models included the light guide, the PMTs, the electronic, the aluminium frame and lead shielding of the corresponding detectors. Acquisition of a ³²P source was also performed on the modelled GSO PET to validate the MC simulation. This setup is an ideal case to study bremsstrahlung emission as no positron emission and no crystal radioactivity are present. **Results:** The singles rate, the true coincidences rate and the radial profile of the ³²P PET acquisition were accurately reproduced when including EB and IB in the simulation, but with a fourfold underestimation when using EB alone. For ⁹⁰Y SPECT and PET, MC simulations showed that about 35% and 65% of the scattered events contaminating the energy acquisition window originated from the EB and from the IB X rays, respectively. MC simulations also showed that IB is the major actor of the spurious extrahepatic activity seen in most post liver ⁹⁰Y radioembolization PET imaging. **Conclusion:** MC simulations show the major impact of the IB in ⁹⁰Y imaging supporting its implementation in the ion source of Geant4. Resulting accuracy improvement in simulations will allow developing better scatter correction.

OP-152

Quantitative SPECT Neuroimaging using a Data Driven Estimation of Attenuation from the Projection Data Alone

X. Ding, A. Vija; Siemens Medical Solutions USA, Inc., Molecular Imaging, Hoffman Estates, IL, UNITED STATES OF AMERICA.

Aims: We present a method to generate a dose-less mu map derived from the SPECT emission data alone. We compare the image quality and regional quantitative uptake of reconstructions using the dose-less mu-map to that using a CT generated mu-map. **Methods:** We perform a non-attenuation compensated SPECT reconstruction using scatter data or primary emission data to generate a binary segmented anatomical volume. A sequence of morphological operations is then applied to the binary images to create a set of final images suitable for skull segmentation. A boundary tracing algorithm is used to identify the skull of the brain. Once the skull is segmented, we calculate the mu value for the skull bone and the mu value for the interior of the skull. The resulting mu-map is then used for SPECT attenuation compensated reconstruction. We compare the reconstructions using the dose-less mu-maps and the mu-maps generated from CTs on 20 clinical brain studies with Tc99m ECD (10) and I123 DATscan (10). For each reconstructed image pair, we create 5 spherical VOIs with random spatial locations within the brain tissue and with random volumes ranging from 1 mL to 10 mL. For each VOI, we calculate the mean, variance and the range of the voxel values inside the VOI. This creates three sets of 100 data pairs to measure the differences between the means, the variances, and the ranges, respectively. We perform the following statistical tests: T-test (T), Wilcoxon (W), and Kolmogorov-Smirnov (KS). **Results:** Visually, the two images reconstructed from the dose-less mu-maps and the CT mu-maps are similar. Quantitatively, the statistical tests (T, W, KS) shows no significant difference between the two reconstructions with $p > 0.5$ for means, variances, and ranges. For the differences between these two reconstructions, the mean of the VOI mean differences is $-2.2\% \pm 3.7\%$; the mean of the VOI standard deviation differences is $-1.6\% \pm 4.9\%$; the mean of the VOI range differences is $-1.6\% \pm 4.9\%$. **Conclusion:** For SPECT brain perfusion studies, quantitative measurements using spheres ranging from 1 mL to 10 mL, have no statistically significant differences between the reconstructions based on the dose-less mu-maps and the mu-maps generated from the CTs. The study indicates feasibility to provide a path to perform quantitative SPECT neuroimaging without additional CT dose. Future work will include a larger population and human observer studies to assess visual and quantitative clinical performance.

OP-153

A 3D-Printed 2-Compartment Kidney Phantom for Evaluating the Accuracy of Quantitative SPECT/CT Imaging

J. Tran-Gia, M. Lassmann; Department of Nuclear Medicine, University of Würzburg, Würzburg, GERMANY.

Aim: Partial-volume correction is among the most crucial, yet challenging corrections in quantitative SPECT/CT imaging. Therefore, the aim of this study was to mimic the renal activity distribution in radionuclide therapies by 3D printing a 2-compartment kidney phantom, and to perform accurate quantitative imaging by including a model-based partial-volume correction. **Materials and Methods:** Acquisition: Siemens Intevo Bold SPECT/CT, 0.95cm crystal, medium-energy collimator, 60 views, 30s-per-view, non-circular orbit. Reconstruction: Flash3D (6-iterations, 6-subsets, no-filtering), xSPECT (48-iterations, 1-subset, no-fil-

tering), CT-based attenuation correction, Triple-energy-window scatter correction. <u>2-Compartment Kidney:</u> Design based on ICRP 89 (Volume: 143.6mL, 70% cortex, 30% medulla). Fabrication (modelling, design, printing) as described in [1]. SPECT/CT acquisitions of the kidney (cortex: ^{177}Lu solution of 1.38MBq/mL, medulla: water) inside a water-filled NEMA body phantom. Repetition after 12 days (~2 half-lifes). <u>SPECT Quantification:</u> Predetermined Flash3D calibration factor (cylindrical 6.7L phantom): 20.22cps/MBq. xSPECT Quant directly computes activity concentration [Bq/mL]. <u>Determination of Spatial Resolution (FWHM):</u> A ^{177}Lu-filled line source (diameter: 1mm) inside a water-filled cylinder (diameter: 20cm) was placed in 5 transverse and 2 coronal positions. The FWHM (≙ resolution) in each line source was determined (average over ~60 slices), and centric-out linear fitting was performed in all 3 spatial dimensions to obtain resolution maps $FWHM_{sagittal}(x,y,z)$, $FWHM_{coronal}(x,y,z)$, and $FWHM_{transverse}(x,y,z)$. Based on these maps, position-dependent average resolutions $<FWHM_{sagittal/coronal/transverse}>$ can be calculated for any imaged object. <u>Partial-Volume Correction:</u> The extracted cortical filling volume (resolution: 0.2mm) was convolved with a non-isotropic Gaussian point-spread-function ($<FWHM_{sagittal}>$, $<FWHM_{coronal}>$, $FWHM_{transverse}>$), and the resulting matrix was resampled to SPECT voxel size (xSPECT: 2.0mm/Flash3D: 4.8mm). The partial-volume correction factor (C_{PV}) was calculated as pseudo-counts in the actual contours divided by pseudo-counts in the entire volume. Additionally, C_{PV} was calculated for spheres of equal volume (99.6mL) using the same average resolution. Finally, activities were calculated by dividing the uncorrected activity (CT-based volume) by C_{PV}. **Results:** While the activity was accurately recovered for Flash3D (deviation<1.3%), the recovery was less accurate for xSPECT (deviation<10.1%). C_{PV} differences of ~30% were found between kidney (xSPECT: 0.628, Flash3D: 0.677) and sphere geometry (xSPECT: 0.837, Flash3D: 0.871). The quantitative accuracy was equivalent (<2% difference) after 12 days. **Conclusion:** Our results suggest that recovery coefficients for partial-volume correction, which are typically assessed in spherical geometries, should instead be assessed based on more realistic geometries. Therefore, the presented combination of numerical partial-volume correction and 3D-printing based validation holds the potential of greatly improving the accuracy in quantitative SPECT/CT. **References:** [1] Tran-Gia, JNM57(12), 2016.

OP-154

Quantitative Lu-177 SPECT/CT validation to assist theragnostic procedures

S. Gnesin[1], T. Lima[2], J. Malterre[3], F. R. Verdun[1], N. Schaefer[3], J. O. Prior[3]; [1]Institute of Radiation Physics, Lausanne university hospital, Lausanne, SWITZERLAND, [2]Kantonal hospital Aarau, Aarau, SWITZERLAND, [3]Department of Nuclear Medicine and Molecular Imaging, Lausanne University Hospital, Lausanne, SWITZERLAND.

Introduction: Similar to PET, absolute quantification has recently become available on commercial SPECT/CT devices with potential benefit for predictive and post-treatment dosimetry. We present a quantitative phantom validation of a commercial SPECT/CT and quantitative protocol optimization in a patient

receiving a therapeutic administration of Lu-177-DOTATATE. **Subjects and Methods:** Quantitative Lu-177 acquisitions were performed on a Symbia Intevo xSPECT/CT (Siemens, Erlangen, Germany). System calibration relies on NIST Se-75 source. We used a NEMA/IEC and an anthropomorphic (Kyoto liver/kidney phantom) phantom including kidneys and liver insert with 20, 30 and 40mm diameter spheres to mimic lesions. Phantom activity concentrations were 20 and 200 kBq/mL in the background and spherical inserts of the NEMA/IEC phantom respectively; 100, 500 and 600 kBq/mL in the liver, lesion inserts and kidneys of the anthropomorphic phantom respectively. xSPECT/CT acquisitions (120 projections, 30s/projection, medium energy low penetration collimator) used attenuation, scatter and resolution recovery corrections. Reconstructions were performed with the proprietary iterative conjugate gradient algorithm. Activity recovery in the organs background, average and maximum recovery coefficients (RC) in lesions and image noise (coefficient of variation) were assessed as a function of iteration number (ITn range: 1-48, ITn step=4, 3D Gaussian smoothing FWHM=10mm). Signal convergence was reached when <5% signal gain was observed when increasing ITn. Average activity recovery in organs and lesions as a function of iteration number was measured in a SPECT/CT acquisition of a patient 3h after therapeutic administration of 6 GBq of Lu-177-DOTATATE. **Results:** For both phantoms, the activity recovery in the background (NEMA/IEC) and organs (anthropomorphic) was within ±6% of the actual value for ITn>16. Activity recovery in lesions ≥28mm converged for ITn≥24, while ITn≥32 was required for smaller insert sizes. In the tested conditions, the 10-mm insert (NEMA/IEC) was not recovered despite the 10:1 lesion-to-background activity concentration. Background noise was always ≤30% in all tested setups. Patient data showed that the average activity concentration converged for 4, 8, 16 and 32 iterations in liver, heart, kidneys and in a 12-mL tumour lesion located in the liver, respectively. **Conclusion:** Quantitative phantom validation showed that standardized procedures applied to Lu-177 xSPECT/CT acquisition/reconstruction protocols enables accurate activity recovery within 6% of actual values in organs. Protocol optimization and RC evaluation were performed to assess quantitative activity recovery in lesions. The validated, vendor-based xSPECT workflow potentially reduces quantitative variability in dosimetry assessment of theragnostic procedures aiming at improving patient care.

OP-155

Quantitative gamma camera imaging of ^{227}Th and ^{223}Ra with application in ^{227}Th targeted alpha therapy

E. Larsson[1], G. Brolin[1], A. Cleton[2], T. Ohlsson[1], C. Hindorf[1]; [1]Radiation Physics, Lund, SWEDEN, [2]Bayer AG, Berlin, GERMANY.

Aim: Thorium-227 (T½=18.7d) is an alpha particle emitting radionuclide and a promising candidate for targeted alpha therapy. Post-therapy gamma camera imaging of ^{227}Th poses a unique challenge due to the low activity administered in current clinical studies (1.4-7 MBq), low photon emission yield and thereby poor signal-to-background ratio. Furthermore, the

daughter-nuclide ^{223}Ra (T½=11.4d) emits photons in the same energy range as ^{227}Th, making it difficult to separate the two nuclides with conventional energy window-based techniques. Here we present a new method for simultaneous quantitative imaging of ^{227}Th and ^{223}Ra, utilizing list-mode data, energy spectrum modelling, and the conjugate-view technique. **Materials and Methods:** The SPECT/CT system (GE, NM670) allows for extraction of measurement data in list-mode format, which was used to generate count-rate energy spectrum on a pixel-by-pixel basis. The natural background spectrum in each pixel was measured and subtracted from the acquired data. For each pixel, a theoretical spectral model was fitted to the background-corrected spectra using a least-square-fit in the energy range 130-380 keV. This model includes components representing primary and scattered photons for ^{227}Th and ^{223}Ra, respectively. The primary spectrum was modelled as a sum of Gaussian functions with parameters reflecting the energy resolution, emission yield, photon attenuation and detector efficiency for every photon emission energy. Photon attenuation was considered by using X-ray scout data for estimation of water-equivalent thickness in each pixel, and model fitting to geometrical mean data. The primary component holds two fitting parameters representing the activity of ^{227}Th and ^{223}Ra, respectively. The amount of scatter is described by two additional fitting parameters. The proposed methodology was validated by measurements using a Jaszczak-phantom filled with ^{227}Th (2.6 MBq) and ^{223}Ra (0.49 MBq). Eleven acquisitions (20 min) were performed between day 0 and 52 post-preparation during which the activity ratio ^{227}Th /^{223}Ra changed from 5.4 to 0.5. **Results:** The quantified activities of ^{227}Th and ^{223}Ra were within 6% and 10%, respectively, of the theoretical values for all time-points. Furthermore, the image quality and radionuclide separation in the resulting activity images were superior to the conventional images based on energy windows acquisition, due to scatter reduction without noise amplification. **Conclusion:** We have developed a new method for quantitative planar gamma camera imaging based on pixel-by-pixel spectral modelling. This method is capable of accurate activity quantification for ^{227}Th and ^{223}Ra at clinically relevant activities and acquisition time. The image quality is superior to conventional energy window-based methods.

OP-156

Comparison of lesion SUVs between ^{99m}Tc-HDP SPECT/CT and ^{18}F-NaF PET/CT

S. Arvola[1], I. Jambor[2], A. Kuisma[3], M. Seppänen[1,4], T. Noponen[1]; [1]Department of Clinical Physiology and Nuclear Medicine, Turku University Hospital, Turku, FINLAND, [2]Department of Diagnostic Radiology, University of Turku, Turku, FINLAND, [3]Department of Oncology and Radiotherapy, University of Turku, Turku, FINLAND, [4]Turku PET Centre, Turku, FINLAND.

Aim: The aim of this study was to evaluate the feasibility of quantitative SPECT for measuring metastatic bone uptake in breast and prostate cancer by comparing the standardized uptake values (SUVs) measured with quantitative ^{99m}Tc-HDP SPECT/CT and ^{18}F-NaF PET/CT. **Materials and Methods:** 26 breast and 27 prostate cancer patients at high risk of bone metastases underwent both ^{99m}Tc-HDP SPECT/CT and ^{18}F-NaF PET/CT within 1-14 days of each other. The SPECT and PET data were corrected for decay, photon attenuation and scatter and reconstructed using the ordered subsets expectation maximization algorithms. Additionally, dead time correction was applied to PET data and collimator correction to SPECT data. SPECT SUVs were calculated using a novel commercially available software: HybridRecon-Oncology v1.3 SUV SPECT (Hermes Medical Solutions, Stockholm, Sweden). From the reconstructed images, lesions visible in both data sets were classified into benign and malignant by an experienced nuclear medicine physician and then segmented from PET images using a threshold of SUV > 15. The threshold was lowered if the resulting volume of interest (VOI) was less than 1 cm^3 and tissue with increased uptake was left outside of the VOI. Finally, the same lesions were segmented from SPECT images using SUV thresholds that resulted in VOIs with sizes similar to those in PET images. Mean and maximum SUVs of the lesions were compared between SPECT and PET, and Spearman's rank correlation coefficients (r_s) were calculated to evaluate the correlations of SUVs between SPECT and PET. **Results:** A total of 200 lesions, 110 metastatic and 90 benign, were segmented. The average thresholds were SUV = 13.0 for PET and SUV = 10.8 for SPECT. The SPECT and PET SUVs correlated strongly with each other; r_s = 0.92 between mean SUVs in metastatic lesions, r_s = 0.84 between maximum SUVs in metastatic lesions, r_s = 0.67 between mean SUVs in benign lesions, and r_s = 0.69 between maximum SUVs in benign lesions. All correlations were statistically highly significant (P < 0.001). In addition, PET mean SUVs were on average 34% higher in benign lesions and 30% higher in malignant lesions, and PET maximum SUVs were 50% higher in benign lesions and 47% higher in malignant lesions than SPECT SUVs. **Conclusion:** The very strong correlation of metastatic SUVs between ^{99m}Tc-HDP SPECT/CT and ^{18}F-NaF PET/CT suggests that quantitative SPECT is feasible for uptake measurements in bone metastases of breast and prostate cancer.

OP-157

Noise and Resolution Analysis of the xSPECT Quant Reconstruction Algorithm for ^{177}Lu

J. Tran-Gia, M. Lassmann; Department of Nuclear Medicine, University of Würzburg, Würzburg, GERMANY.

Aim: Quantitative assessment of radioactivity distributions is critical for molecular radiotherapies. Therefore, the aim of this work was to evaluate the noise and resolution characteristics of the recently presented xSPECT Quant reconstruction method for ^{177}Lu-based quantitative SPECT/CT imaging. **Materials and Methods:** Acquisition: Siemens Intevo Bold SPECT/CT, 0.95-cm crystal, medium-energy collimator, 60 views continuous, equivalent non-circular camera orbits. Reconstruction: 6 to 96 iterations, 1 subset, no filtering, CT-based attenuation correction, triple-energy-window scatter correction. Line-Source-Based Resolution: Two line-sources (diameter: 1mm) filled with a ^{177}Lu solution were placed in the central

and the outermost position (9cm off-center) of a water-filled cylindrical phantom (diameter: 20cm). By axially rotating the phantom before each acquisition, the spatial resolution at 5 different transverse positions was investigated (7.9M counts, rotation angles: 0°/90°/180°/270°). Edge-Based Resolution: Six spheres of a water-filled body phantom (PTW-Freiburg: NE-MA-NU2-2012) were filled with a ^{177}Lu solution. Additionally to a standard SPECT/CT acquisition (4.2M counts), a high-resolution CT (1-mm isotropic) was acquired to derive a numerical phantom mask. SPECT image formation was simulated by convoluting this mask with a Gaussian-shaped point-spread-function and resampling the resulting matrix to a 2-mm grid. After applying Gaussians of different FWHMs, the minimum root-mean-squared error between the reconstructed and the simulated volumes is associated to the most probable point-spread-function ($\triangleq$ resolution). Noise Analysis: SPECT/CT acquisitions were performed with a ^{177}Lu-filled cylindrical Jaszczak phantom (6.7L, 30s/60s per view, 8.0M/16.1M counts). The noise coefficient of variation was calculated as the ratio between standard deviation and mean value of counts within a large VOI (2.0L) inside the cylinder. **Results:** The resolution is considerably improved (3-fold) by an increasing number of iterations (center/off-center: 19.4/13.1mm for 6 iterations → 7.6/4.4mm for 96 iterations). The FWHM of the point-spread-function depends on the off-center distance and increases with the proximity to the detectors (about 35% difference between center and 9cm off-center). The edge-based resolution is in accordance with the centrally placed line-source (18.4mm for 6 iterations, 9.1mm for 96 iterations). While the noise level decreases with the scan duration, it increases with the number of updates (30/60s-per-view: 0.06/0.04 for 6 iterations → 0.28/0.19 for 96 iterations). **Conclusion:** In xSPECT, considerable resolution improvement by an increasing number of iterations comes at the cost of a strong noise increase. As recommended by the vendor, 48 iterations represent a reasonable trade-off between resolution enhancement and noise minimization. Despite resolution-recovery, the FWHM is not spatially invariant.

OP-158

Quantitative SPECT Imaging of Thorium-227: A phantom experiment

M. Ghaly, Y. Du, G. Sgouros, D. Thorek, E. C. Frey; Johns Hopkins University, Baltimore, MD, UNITED STATES OF AMERICA.

The radionuclide Thorium-227 and its daughter nuclide Radium-223 are important nuclides for alpha immunotherapy. However, quantitative SPECT imaging of Thorium-227 is challenging because of the low yield of photons, complicated emission spectrum and its decay to Radium-223. We have previously developed a model of the image formation process and validated it using Monte Carlo simulations. Here we incorporate that model into an OS-EM reconstruction algorithm and evaluate its ability to quantitatively reconstruct Thorium-227 activity distributions using a phantom study. Thorium-227 was purified immediately before the experiment from a laboratory scale chromatography

column, pre-treated with 80:20 mixture of methanol:nitric acid, utilizing immobilized parent Actinium-227. A 3-cm diameter sphere was filled with a solution containing 2 micro-curies of Thorium-227. We imaged the sphere placed inside an empty and a water-filled cylinder phantom using a Siemens Symbia Intevo dual-head SPECT/CT system with a 9.5 mm thick NaI(Tl) crystal and a medium energy-low penetration (ME-LP) collimator. Images were acquired at 64 views over 360, a 20% window centered at 84keV, a 15% window centered at 236keV and total acquisition time of 60 and 240 minutes for the empty and water-filled cylinders, respectively. We reconstructed the projection data using an OS-EM-based iterative reconstruction algorithm that models attenuation, scatter and the collimator-detector response (CDR) for all the relevant photopeaks. Scatter was modeled using the effective-source scatter estimation (ESSE) method; pre-computed CDR tables were used to model the interactions in the collimator-detector system including septal penetration and scatter. We evaluated the quantitative accuracy of the estimated activities in the sphere and the different imaging scenarios. A volume-of-interest over the sphere was defined based on the CT map. The percent errors in the reconstructed activities in the sphere were -11.5 +/- 4.1% and -12.4 +/- 4.9% in the empty and water-filled cylindrical phantoms, respectively. We also observed very good agreement between the Monte Carlo simulated Thorium-227 projections and those acquired on the system. Quantitative Thorium-227 imaging in the absence of its Radium-223 daughter is feasible when using good models of the image formation process. Further improvements are expected by refining the projection model and using more iterations and partial-volume compensation to reduce partial volume effects. Clinical quantitative Thorium-227 imaging is feasible by combining previously-developed Radium-223 imaging and dual isotope reconstruction methods.

OP-160

Combination of Proton Irradiation and Targeted Radionuclide Therapy with 177Lu-PSMA-617 in a Tumor Mouse Model of Prostate Cancer

C. Mueller, R. Perrin, C. Umbricht, N. van der Meulen, S. Safai, D. Weber, A. Lomax, R. Schibli; Paul Scherrer Institut, Villigen-PSI, SWITZERLAND.

Aim: Proton therapy allows the precise local deposition of therapeutic radiation doses to the tumor, whereas radionuclide therapy can target disseminated cancer cells. The combination of proton therapy and radionuclide therapy may, thus, be of unparalleled value for the treatment of patients with a non-resectable primary tumor with or without metastases. The goal of

this study was to perform the first proton therapy/radionuclide therapy combination using mice with subcutaneous prostate tumor xenografts. Furthermore, the precision of proton therapy was investigated via PET, imaging activation products in proton-irradiated tumors. **Material and Methods:** Proton irradiation was performed at the OPTIS2 facility at Paul Scherer Institut. The proton field was collimated to the tumor size with a 2.5 mm margin. Irradiation was achieved with a Spread-Out-Bragg Peak, produced from scattering and modulation of a 75 MeV beam, to achieve a uniform dose to subcutaneous PC-3 PIP prostate tumor xenografts. Radionuclide therapy was applied using ^{177}Lu-PSMA-617. Mice (Balb/c nude) were divided into four groups (n=5). Group A: untreated; Group B: 10 Gy proton therapy; Group C: treated with ^{177}Lu-PSMA-617 (5 MBq, ~20 Gy mean absorbed tumor dose); Group D: combination therapy (5 Gy proton therapy and 5 MBq radionuclide therapy). The mice of each group were monitored with weight and tumor size over a period of 9 weeks. Endpoint criteria were defined as weight loss >15% or tumor volume >1cm³. Proton-irradiated mice were scanned for 10 min using a preclinical PET/CT scanner. **Results:** High-quality static PET/CT scans revealed activation products precisely in the irradiated tumor tissue and the absence of activity in the surrounding tissue. The tumor growth inhibition at Day 16 was 83.5% (Group B), 90.8% (Group C) and 95.2% (Group D). The time to reach a relative tumor volume of 2.5 (tumor growth delay index 2.5), was 2.8-fold (Group B), 4.3-fold (Group C) and 5.5-fold (Group D), longer, respectively, as compared to untreated controls (Group A). The mean survival time was 23 days for control mice, 30 days for mice irradiated with protons and 36 days for mice treated with ^{177}Lu-PSMA-617. Combination of proton therapy (5 Gy) and radionuclide therapy (20 Gy) resulted in a mean survival time of 56 days. **Conclusions:** The encouraging results of these studies warrant detailed investigations with regard to the benefit of combining proton therapy and radionuclide therapy in tumor models of prostate cancer and other tumor types.

OP-161

In Vivo Assessment of p53 Therapy as a Way of Enhancing Therapeutic Effects of Radiation

A. C. Mortensen[1], D. Spiegelberg[1], S. Lundsten[1], C. Brown[2], D. P. Lane[2,3], M. Nestor[1]; [1]Department of Immunology, Genetics and Pathology, Uppsala University, Uppsala, SWEDEN, [2]p53 Lab, A*STAR, 8A, Biomedical Grove, #06-04/05 Neuros/Immunos, Singapore 138648, Singapore, SINGAPORE, [3]Department of Microbiology, Tumor and Cell Biology, Karolinska Institutet, Stockholm, Stockholm, SWEDEN.

Introduction: Several small HDM2-p53 antagonists are currently undergoing clinical trials as new, targeted cancer therapies either as monotherapies or in combination with cytostatic drugs. However, the role of wt p53 during radiation response mechanisms suggests a potential for utilizing such peptides in combination with ionizing radiation in order to enhance therapeutic effects. In this study, we explored the efficacy of the novel HDM2/HDMX-p53 antagonist PM2, and examined its effects in combination with external beam radiotherapy (EBRT) in both cultured human tumor cells and in tumor bearing mice. **Subjects and Methods:** The therapeutic effects of PM2-therapy *in vitro*, both as a single modality and in combination with ionizing radiation, were first evaluated in a panel of cancer cell lines using cell viability, clonogenic survival, and 3D tumor spheroid assays. Flow cytometry and Western Blot experiments assessed p53-mediated cellular responses. Potential synergistic effects of fractionated PM2-therapy and ionizing radiation were evaluated in a mouse xenograft model with wt p53 and p53 knockout (-/-) tumors, where tumor growth was followed over time. Furthermore, ^{125}I-labeled PM2 was used to study the biodistribution of the peptide *in vivo*. **Results:** PM2-therapy induced cytotoxic activity both alone and in combination with EBRT in wt p53 cell lines in both monolayer and 3D tumor spheroids, where PM2-therapy in combination with EBRT resulted in synergistic therapeutic effects. Flow cytometry and Western Blot confirmed increased apoptotic activity in the combination samples. *In vivo*, the combination of PM2-therapy and EBRT significantly prolonged survival compared to the control and single treatment groups in wt p53 xenografts. Biodistribution of ^{125}I-PM2 revealed high tumor uptake retained in the tumor for at least 24 h p.i., and digital autoradiography revealed peptide distribution throughout the tumor. Effects on p53 -/- tumors were negligible. **Conclusion:** PM2-therapy enhances the effects of EBRT in cells that retain a wt p53 expression. In the future, a clinical application of PM2-therapy in combination with radiotherapy may be a promising strategy of enhancing the effects of radiotherapy and restore quality of life in cancer patients.

OP-162

Improvement of peptide receptor radionuclide therapy effects via modulation of the DNA damage response

J. Nonnekens, M. de Jong, D. C. van Gent; Erasmus MC, Rotterdam, NETHERLANDS.

Aim: Peptide receptor radionuclide therapy (PRRT) of metastasized neuroendocrine tumors (NETs) that overexpress somatostatin receptors (SSTR) strongly increases progression-free survival and life quality. Recently phase III clinical trials using Lutetium-177 coupled to the somatostatin analogue DOTA-[Tyr³] octreotate (Lutathera® or ^{177}Lu-DOTA-TATE) were finalized. This therapy eradicates tumor cells by targeting DNA damaging radionuclides to the tumor cells with limited harm to healthy tissue. The clinical results are favorable, but most patients will eventually succumb to the disease. Therefore, adaptations of the therapy are urgently needed. We aimed to increase the damaging potential of PRRT via combination therapy with DNA damage response (DDR) inhibitors without extra harm to the healthy tissues. **Materials and methods:** To better understand the radiobiological effects of PRRT, we characterized DNA damage and the DDR induced by NET PRRT. As models, we used SSTR positive cell lines and *ex vivo* cultured human tumor slices. Cells or tissue slices were treated with different doses of ^{177}Lu-DOTA-TATE, followed by non-radioactive incubation for different periods until 7 days post treatment. During these chases the cells/ tissues were treated with inhibitors of PARP, DNA-PK or ATM.

Cells/tissues were fixed and fluorescently stained with different antibodies (53BP1, gamma-H2AX) to visualize the accumulation of DNA repair proteins to the produced DNA double strand breaks (DSBs). Cell proliferation was measured using EdU incorporation and Click-iT labeling technology. Furthermore, cellular survival was measured using colony assay and sulforhodamine B colorimetric assay. **Results:** PRRT produced different types of DNA damage and triggered the DDR in SSTR-positive cells and tumor slices. Combination treatment of PRRT with all of the DDR inhibitors showed radiosensitization and at least 2 fold increase of cell death compared to PRRT alone. PARP-inhibition increased the number of DSBs, leading to increased cytotoxicity, while ATM- and DNA-PK-inhibition caused prolonged existence of the DSBS leading to genome instability and cell death. **Conclusion:** DDR inhibitors can be used to sensitize PRRT in preclinical studies. We expect that our results will eventually improve current NET PRRT that will lead to increased patient survival rates.

OP-163

In Vitro and In Vivo Growth Inhibitory and Radiosensitizing Effects of the Anti-HSP90 agent Onalespib

D. Spiegelberg, S. Lundsten, A. C. Mortensen, A. Abramenkovs, B. Stenerlöw, M. Nestor; Department of Immunology, Genetics and Pathology, Uppsala University, Uppsala, SWEDEN.

Background and Aims: The chaperone Heat shock protein 90 (HSP90) activates and stabilizes numerous oncogenic client proteins. HSP90 overexpression is associated with increased tumor cell survival and growth. The novel HSP90 inhibitor Onalespib is currently in clinical trials, promoting degradation of oncogenic proteins, and may also act as a radio-sensitizer. The aim of this study was to evaluate the response to Onalespib treatment in combination with external beam gamma radiotherapy in 2D and 3D cell assays as well as in mouse xenograft models. **Materials and Methods:** Flow cytometry, immunoblotting, confocal microscopy and radio-immunoassays were used to evaluate the effect of Onalespib on client protein expression and cytotoxicity *in vitro*. Inhibitor effects on protein expression and tumor size were assessed *in vivo* in combination with external beam radiation. **Results:** Onalespib treatment downregulates HSP90 client proteins both *in vitro* and *in vivo*. Treatment alone and in combination with radiation reduced cancer cell proliferation, cell migration rates and increased apoptosis. Furthermore, cells accumulated in the more radio-sensitive G2/M phase of the cell cycle. *In vivo*, a minimal treatment regimen during 3 consecutive days of Onalespib (3×50mg/kg) in combination with external beam gamma radiation (3×2Gy) caused a substantial tumor growth delay and prolonged the survival by a factor of 3 compared to the control groups. **Conclusion:** Our results demonstrate that Onalespib is a potent radiosensitizer with a potentially broad therapeutic window. We speculate that the depletion and downregulation of HSP90 client proteins involved in cancer cell signaling and DNA damage repair mechanisms is the cause. Thus, individually, or in combination Onalespib has the potential to reduce tumor cell growth and may improve radiotherapy outcomes in cancer patients.

OP-164

Boramino Acid: A New Theranostic Platform Serves Imaging Guided Boron Neutron Capture Therapy

J. Li, Y. Han, Z. Liu; Peking University, Beijing, CHINA.

Objective: A new class of amino acid mimics—boramino acids (BAAs)—are described here that can serve as theranostic boron delivery agents for imaging guided BNCT cancer treatment. The structure of a BAA is identical to that of the corresponding natural amino acid, except for an exotic replacement of the carboxylate with trifluoroborate. Cellular studies demonstrate the cell uptake of BAA is strongly mediated to amino acid transporter, of which the abnormal expression is often associated with cancer. In addition, animal studies of ^{18}F labeled BAA (^{18}F-BAA) show high tumor-specific accumulation with PET (positron emission tomography), suggesting that BAA holds great promise for the development of new PET imaging probes and AAT-targeting boron agents for BNCT cancer therapy. **Method:** A boron-derived Tyrosine (B-Tyr) derivative was synthesized to mimic Tyr, of which the transportation depends on L-type amino acid transporter (LAT). [18]F-^{19}F isotope exchange reaction was conducted for radiolabeling and quality control was performed by both HPLC and radioTLC. The metabolic stability of B-Tyr was assessed both *in vitro* and *in vivo*. PET imaging were performed in mice bearing UM22B xenografts, and ^{18}F-B-Tyr is co-injected with 10 mg of unlabeled boron-derived Tyr. The animals are sacrificed right after PET scan, and organs are collected for ICP analysis. **Result:** At 60 min post injection, ^{18}F-B-Tyr shows high accumulation in UM22B tumor (11.9 ± 2.7 %ID/g) but demonstrates low uptake in the rest of the body (liver, 2.41 ± 0.36 %ID/g; muscle, 1.98 ± 0.54 %ID/g; brain, 0.35 ± 0.13 %ID/g and blood, 1.19 ± 0.47%ID/g). The tracer had predominant renal clearance but with low kidney retention. The following ICP analysis is correlated with PET imaging and shows high boron accumulation in tumor (66.7 ± 11.5 ppm) with good selectivity on healthy tissues (liver, 13.5 ± 2.1 ppm; muscle, 12.1 ± 1.9 ppm; brain, 5.9 ± 1.3 ppm and blood, 7.8 ± 2.0 ppm). **Conclusion:** A boron-derived Tyr derivative was developed and evaluated for PET-guided BNCT treatment. Administration of ^{18}F-B-Tyr allowed for clear visualization of tumor xenografts, and also delivers high concentration of boron atoms into tumor that can be promising for BNCT treatment.

OP-165

Second Generation Trifunctional PSMA Binding Ligands with Application to the Imaging of Prostate Cancer by Positron Emission Tomography and to its Treatment by Targeted Endoradiotherapy

J. M. Kelly[1], A. Amor-Coarasa[1], S. Ponnala[1], A. Nikolopoulou[1,2], C. Williams, Jr[1], D. Kim[2], J. W. Babich[1,2,3]; [1]Division of Radiopharmaceutical Sciences and MI3, Department of Radiology, Weill Cornell Medicine, New York, NY, UNITED STATES OF AMERICA, [2]Citigroup Biomedical Imaging Center, Weill Cornell Medicine, New York, NY, UNITED STATES OF AMERICA, [3]Sandra and Edward Meyer Cancer Center, Weill Cornell Medicine, New York, NY, UNITED STATES OF AMERICA.

Aim: Treatment of late-stage prostate cancer (PCa) by targeted radiotherapeutics such as ^{131}I-MIP-1095 and ^{177}Lu-PSMA-617 has shown encouraging early results. However, many patients never respond to β-particle therapy, and relapse rate remains high. Recently, treatment of PCa by targeted alpha therapy (TAT) with [213]Bi-PSMA-617 and [225]Ac-PSMA-617 has been shown to overcome resistance to beta particles, but severe, irreversible xerostomia and dry eye are dose-limiting toxicities. We recently proposed albumin binding as a strategy for improving the pharmacokinetics of PSMA-targeting small molecules and introduced a radioiodinated dual-binding ligand, RPS-027, that shows good tumor uptake and significantly reduced kidney uptake in a preclinical model. Further development is limited by the inability to independently modify either PSMA or albumin binding. We therefore devised a new class of trifunctional ligands with (1) a high affinity PSMA binding domain; (2) a chelator for radiometals such as Ga^{3+}, $^{177}Lu^{3+}$ and $^{225}Ac^{3+}$; and (3) an HSA binding group all linked by a flexible chemical moiety, and to compare these ligands in LNCaP cells and in LNCaP tumor xenografts with a view towards a next generation ligand for treatment of PCa by TAT. **Materials and Methods:** Six compounds were synthesized, incorporating a triazolylphenylurea-containing PSMA-targeting group, an N^ε-(2-(4-iodophenyl)acetyl)lysine albumin-binding group (ABG) and the bifunctional chelator DOTA. These moieties were linked by a PEG-containing polymer containing 0,3,4,6,8 or 12 repeats. The affinity of the compounds for PSMA was determined in LNCaP cells and their uptake and tissue distribution was studied in mice bearing LNCaP tumor xenografts. Imaging studies were performed using $^{68}Ga^{3+}$ and $^{66}Ga^{3+}$ and biodistribution studies with $^{177}Lu^{3+}$. RESULTS: Affinity for PSMA was in the range 1-20 nM, and it was inversely proportional to the linker length. In agreement with their binding affinities, uptake of the ligands in tumors was in the order RPS-068(PEG$_0$)>RPS-061(PEG$_4$)>RPS-066(PEG$_8$)>RPS-067(PEG$_{12}$). Important differences were observed in kidney uptake, with RPS-068≈RPS-061>>RPS-066≈RPS-067. A trend of increasing hepatobiliary excretion was observed with increasing linker length. Blood clearance was similar for all of the ligands. **Conclusion**: Although tumor uptake of RPS-068 and RPS-061 was higher than RPS-066 and RPS-067, kidney uptake of the latter compounds decreased ten-fold, leading to greater tumor-to-kidney ratios. The similar blood clearance curves indicate that this pharmacokinetic parameter is mainly driven by the ABG. Ultimately the combination of good tumor uptake and excellent tumor-to-kidney ratios makes the constructs with a linker of length PEG$_4$-PEG$_8$ the more promising candidates for TAT.

Peptide receptor radionuclide therapy in combination with lanreotide Autogel/Depot: a retrospective study in progressive digestive and bronchopulmonary neuroendocrine tumours (PRELUDE)

V. Prasad[1], R. Srirajaskanthan[2], C. Toumpanakis[3], C. M. Grana[4], T. Shah[5], J. Valle[6], F. Courbon[7], X. Truong Thanh[8], A. Houchard[8], L. Bodei[9]; [1]Charité Universitätsmedizin Berlin, Berlin, GERMANY, [2]King's College Hospital NHS Foundation Trust, London, UNITED KINGDOM, [3]Royal Free Hospital, London, UNITED KINGDOM, [4]Instituto Europeo di Oncologia, Milan, ITALY, [5]Queen Elizabeth Hospital, Birmingham, UNITED KINGDOM, [6]The Christie NHS Foundation Trust, Manchester, UNITED KINGDOM, [7]IUCT Oncopole, Toulouse, FRANCE, [8]Ipsen, Boulogne-Billancourt, FRANCE, [9]Memorial Sloan Kettering Cancer Center, New York, NY, UNITED STATES OF AMERICA.

Introduction Therapeutic options for progressive neuroendocrine tumours (NETs) are limited. Peptide receptor radionuclide therapy (PRRT), however, has the potential to control such tumours and has been used with somatostatin analogues such as lanreotide Autogel/Depot (LAN). The aim of the PRELUDE study is to investigate the effectiveness and safety of PRRT in combination with LAN (LAN-PRRT) in progressive gastroenteropancreatic (GEP)- and lung NETs. **Subjects & Methods** This international, retrospective, non-comparative study will analyse existing records for approximately 150 patients from France, Germany, Italy and the UK who received LAN-PRRT (NCT02788578). Key inclusion criteria for eligible adults are: a metastatic/locally advanced, well-differentiated (grade 1/2), functioning or non-functioning GEP- or lung NET; progressive disease confirmed from imaging conducted within the previous 12 months and in the 6 months before the first LAN-PRRT cycle; positive somatostatin-receptor status; ECOG performance status score ≤2; at least one LAN injection in 8 weeks prior to first LAN-PRRT cycle; no prior PRRT; continuous LAN between all cycles; total cumulative activity of ≥500 mCi of ^{177}Lu-DOTATOC or ^{177}Lu-DOTATATE. Data will be collected retrospectively for three timepoints: before treatment on day 1 of the first LAN-PRRT cycle (baseline), at the end of the last cycle, and at the last available follow-up (≤12 months after treatment). **Results** The primary endpoint is the progression-free survival (PFS) rate at the end of last LAN-PRRT cycle (response evaluation in solid tumours [RECIST] v1.1, assessed centrally). Secondary effectiveness endpoints include: PFS rate at the last available follow-up visit; best overall response; objective response rate after last cycle and at last follow-up (percentage of patients with a complete or partial response); changes from baseline to last cycle and last follow-up in the presence and severity of diarrhoea and flushing; changes from baseline to last cycle in chromogranin-A level. Safety endpoints include: changes from baseline to last cycle and last follow-up in body weight; incidences of nephro-, haemato- and hepatotoxicities; incidence of vomiting during infusion. Exploratory endpoints include: median PFS (RECIST v1.1);

median overall survival (OS); baseline factors associated with OS; association between immunoreactive and Krenning scores for somatostatin receptor 2. **Conclusion** PRELUDE will assess LAN-PRRT effectiveness and tolerability in a sizeable cohort of patients with progressive GEP- and lung NETs, and thus further our understanding of the benefits of combined somatostatin analogue and PRRT therapy. As of 20 April 2017, 38 patients have been included. *Sponsored by Ipsen*

OP-168

Clinical, tumour, and treatment parameters to predict overall survival after PRRT - a multivariate analysis in 783 patients

E. A. Aalbersberg[1], D. M. V. Huizing[1], H. R. Kulkarni[2], I. Walraven[3], B. J. de Wit - van der Veen[1], A. Singh[2], M. P. M. Stokkel[1], R. P. Baum[2]; [1]Department of Nuclear Medicine, ENETS Center of Excellence, Netherlands Cancer Institute – Antoni van Leeuwenhoek, Amsterdam, NETHERLANDS, [2]THERANOSTICS Center for Molecular Radiotherapy, ENETS Center of Excellence, Zentralklinik Bad Berka, Bad Berka, GERMANY, [3]Department of Radiation Oncology, ENETS Center of Excellence, Netherlands Cancer Institute – Antoni van Leeuwenhoek, Amsterdam, NETHERLANDS.

Introduction: Peptide receptor radionuclide therapy (PRRT) is an effective treatment option in patients with metastatic neuroendocrine tumours (NET). With increasing referral for PRRT, patient selection to benefit from treatment and prediction of the expected outcome, is becoming increasingly important. Factors such as tumour grade and Ki-67 have been shown to influence the outcome of PRRT in smaller studies. However, no large multivariate analyses on overall survival after PRRT have been performed. The aim of this study was to investigate the association between clinical factors, tumour characteristics, prior treatments, and PRRT parameters on the outcome of PRRT measured as overall survival (OS). **Materials and Methods:** All patients treated between October 2002 and August 2016 with at least three consecutive cycles of PRRT within six months of the previous cycle were included. General patient characteristics (performance status, presence of hypertension and diabetes), tumour characteristics (primary tumour location, grade, functional status, and Ki-67), prior treatment to PRRT (interferon, chemotherapy, radiotherapy, surgery of the primary tumour, ablation, or SSA), and treatment characteristics (peptide, isotope, and administered activity) were taken into account. OS was calculated as time from the last PRRT cycle to date of death or last follow-up. First, univariate cox proportional hazards analyses were performed to identify variables potentially associated with OS. Consequently, a multivariate cox proportional hazards model was constructed with variables associated ($P < 0.1$) with OS using a backward selection procedure, leaving only variables significantly ($P < 0.05$) associated with OS. **Results:** 783 patients were included in the multivariate analyses. The median OS was 44.0 months (interquartile range 21-89 months). Grade 3 tumours [HR 2.03 (95% CI 1.31 to 3.15)], performance status of either WHO 1 [HR 1.61 (95% CI 1.22 to 2.13)] or WHO 2 [HR 2.47 (95%CI 1.60 to 3.81)] compared to WHO 0, previous chemotherapy [HR 1.80 (95% CI

1.36 to 2.39)], or a previous tumour ablation [HR 1.48 (95% CI 1.05 to 2.09)] were significantly associated with a worse OS. Resection of the primary tumour was significantly associated with an improved OS after PRRT [HR 0.73 (95% CI 0.57 to 0.94)]. **Conclusion:** In 783 patients, the median overall survival after PRRT was 44 months. A higher tumour grade, poorer performance status, and previous chemotherapy or tumour ablation predict a worse overall prognosis. Resection of the primary tumour was significantly associated with improved overall survival.

OP-169

A Prospective study of Peptide Receptor Radionuclide Therapy with 177Lu-DOTATATE and Concurrent Capecitabine in Metastatic Paragangliomas

S. Ballal, M. P. Yadav, D. Yadav, C. Bal; All India Institute of Medical Sciences, New Delhi, INDIA.

Aim: Paragangliomas are rare tumors, 30% of which are malignant. They are highly aggressive and have a poor prognosis when metastatic. Peptide Receptor Radionuclide Therapy (PRRT) is currently utilized in their management due to somatostatin receptor expression in these tumors. Capecitabine has been used as a radiosensitizer during PRRT treatments for other neuroendocrine tumors. This study was done to evaluate the efficacy and toxicity of PRRT with concurrent capecitabine in patients with metastatic paragangliomas. **Methods:** 20 patients of metastatic paragangliomas who had positive somatostatin receptor expression, were enrolled in the study. All patients underwent baseline ^{68}Ga-DOTA-NOC PET/CT scans and were treated with 7.8GBq ^{177}Lu-DOTATATE therapy quarterly and concurrent oral capecitabine 1,250mg/m^2 for 15 days starting from the day of PRRT infusion. Toxicity profile and Chromogranin A (CgA) levels were recorded before, and after therapy at 2 weeks, 4 weeks and 3 months. Toxicity was assessed using CTCAE v4.0 and post therapy morphological response using RECIST1.1 criteria. **Results:** Median age of patients was 36.5yr (range 22-47). Post two to six cycles of PRRT, 18.75% patients had partial response (PR), 56.25% patients had stable disease (SD), and 25% had progressive disease (PD). Only 12.5% patients had biochemical progression whereas rest showed significant decline in CgA levels (median CgA decline 5%). The median follow up was 15 months (range 9-60). The 2-yr progression free survival was 69.2% and 2-yr overall survival was 57.8%. One patient had renal toxicity; two patients had grade II haematological toxicity while Grade III/IV toxicity was not seen in any of the patients. **Conclusion:** Concomitant Capecitabine and ^{177}Lu-DOTATATE therapy offers a good progression-free survival and overall survival with negligible toxicity noticed during the period of study. Patients with aggressive disease have limited management options and may benefit from this synergetic therapeutic approach. Longer follow-up of these patients is needed to elucidate survival advantage.

OP-170

First-in-human PET/CT Imaging of somatostatin receptor expressing tumors with the novel somatostatin receptor antagonist ^{68}Ga-NODAGA-LM3 - a comparison with ^{68}Ga-DOTATOC PET/CT

A. Singh[1], H. R. Kulkarni[1], T. Langbein[1], D. Müller[1], S. Senftleben[1], M. Fani[2], H. Maecke[3], R. P. Baum[1]; [1]Theranostics Center for Molecular Radiotherapy and Molecular Imaging, Bad Berka, GERMANY, [2]Division of Radiopharmaceutical Chemistry, University Hospital of Basel, Basel, SWITZERLAND, [3]Department of Nuclear Medicine, University Hospital Freiburg, Freiburg, GERMANY.

Aim: Since over two decades somatostatin receptor (SSTR) agonists are being used for molecular imaging of SSTR-expressing tumors. A recent clinical study with SSTR-antagonist based PET/CT reported a higher tumor detection rate in SSTR-expressing tumors than SSTR-agonist based PET/CT. This study aims to assess the suitability of ^{68}Ga-based PET/CT imaging of the SSTR-antagonist LM3 [p-Cl-Phe-cyclo(D-Cys-Tyr-D-4-amino-Phe(carbamoyl)-Lys-Thr-Cys)D-Tyr-NH$_2$] conjugated to the chelator NODAGA (1,4,7-triazacyclononane,1-glutaric acid-4,7-acetic acid) in humans with SSTR-expressing tumors, and compare it with the SSTR-agonist ^{68}Ga-DOTATOC PET/CT. **Methods**: NODAGA-LM3 was labeled with ^{68}Ga (radiochemical yield >95%, radiochemical purity >95%, specific activity 20-50 MBq/nmol). Two patients, one with pancreas NEN (P1) and other with paraganglioma (P2), who had previous ^{68}Ga-DOTATOC PET/CT within 3 months for direct comparison, were included in this study. Five other patients had ^{68}Ga-NODAGA-LM3 PET/CT (LM3), but with ^{68}Ga-DOTATOC PET/CT (TOC) performed at >3 months' time-interval, were excluded. ^{68}Ga-NODAGA-LM3 was administered to P1 (289 MBq) and P2 (286 MBq), followed by PET/CT imaging at 50 min p.i. The acquired LM3 and the corresponding TOC images were compared visually and semi-quantitatively. Tumor-to-background ratios (TBR) were calculated using volume-of-interest based SUVmax for 5 target lesions (TL) and SUVmean for reference tissue (RT) including the liver, kidney, gluteus muscle, and spleen (P2 only). **Results**: Molecular imaging with ^{68}Ga-NODAGA-LM3 PET/CT demonstrated excellent image quality with high specific uptake in the liver, lymph node, skeletal, and soft tissue metastases, as well as in multifocal paraganglioma. Visually, ^{68}Ga-NODAGA-LM3 PET/CT distinctively detected additional SSTR-expressing lesions (P1 n=10, namely, liver n=3, lymph node n=1, bone n=6; P2, n>140 skeletal metastases). The physiological uptake of ^{68}Ga-NODAGA-LM3 compared to ^{68}Ga-DOTATOC (SUVmean LM3:TOC) in RT was higher for kidney (P1, 11.7:4.6; P2, 10:6.3) and gluteus (P1, 0.73:0.35; P2, 0.44:0.38), but lower for liver (P1, 3.5:4.2, P2, 3.7:5.4) and spleen (P2, 13.9:26.5). Applying the same TL, ^{68}Ga-NODAGA-LM3 associated TBR (LM3:TOC) for P1 were higher for all RT (liver 5:0.3; kidney 1.5:0.4; gluteus 25:5); whereas, for P2, they were higher for liver (48:4) and spleen (13:7), but lower for the kidney (18:3) and gluteus (405:507). **Conclusion**: In this study, PET/CT imaging with the SSTR-antagonist ^{68}Ga-NODAGA-LM3 in comparison to the SSTR-agonist ^{68}Ga-DOTATOC demonstrated a higher rate for the detection of SSTR-expressing tumor and metastases, both visually and semi-quantitatively. Despite the limited number of patients, our findings confirm recently reported results comparing radiolabeled SSTR-antagonists with agonists. Additionally, our results emphasize the potential of the SSTR-antagonist ^{68}Ga-NODAGA-LM3 for PET/CT imaging of SSTR-expressing tumors in humans.

OP-171

Biodistribution and radiation dosimetry of ^{68}Ga-DOTA-JR11 in patients with metastatic neuroendocrine tumors

S. Krebs, J. O'Donoghue, D. Reidy, N. Pandit-Taskar, B. Beattie, L. Bodei, W. A. Weber; Memorial Sloan Kettering Cancer Center, New York, NY, UNITED STATES OF AMERICA.

Purpose: Somatostatin receptor (SSTR) imaging is widely used for the management of patients with neuroendocrine tumors (NETs). In this study we assess the utility of the novel somatostatin antagonist ^{68}Ga-DOTA-JR11 for PET imaging of NETs. Patients with advanced NETs and positive ^{111}In-pentetreotide (OctreoScan®) scans, who were candidates for peptide receptor radionuclide therapy (PRRT) with ^{177}Lu-DOTA-JR11, were imaged with ^{68}Ga-DOTA-JR11 to assess biodistribution and radiation dosimetry. **Methods:** 19 patients underwent whole-body PET/CT imaging (GE PET/CT 710 scanner; PET acquisition 60-70 minutes postinjection; 173 MBq (median) ^{68}Ga-DOTA-JR11). Volumes of interest were placed over up to 4 ^{68}Ga-DOTA-JR11 avid lesions (with uptake greater than liver). Maximum standardized uptake value (SUVmax), SUVmean and SUVpeak were measured on ^{68}Ga-DOTA-JR11 PET. Additionally, target-to-normal blood (TNR blood) and target-to-normal spleen (TNR spleen) ratios were calculated as quantitative indices. A subset (3 females, 3 males) had additional imaging for absorbed dose estimation purposes (25 min dynamic PET/CT scan of the upper abdomen including, at least partly, cardiac left ventricle, liver, spleen and kidney and a whole-body PET/CT scan at 30 min post-injection). Absorbed doses were calculated using OLINDA/EXM. **Results:** In contrast to the known biodistribution of SSTR2 agonists, no/minimal uptake above background was seen in pituitary gland, spleen, adrenals and liver; e.g. spleen SUVmean 1.49 (0.66-1.81), liver SUVmean 1.15 (0.66-1.88). A total of 40 lesions were analyzed on whole-body ^{68}Ga-DOTA-JR11 PET/CT with median SUVmax 11.7 (range: 2.87-94.47), SUVpeak 9.37 (2.46-84.07), TNR blood 9.32 (1.85-86.7) and TNR spleen 4.87 (1.87-47.63). In the 6 patients, who had dynamic imaging, tumor lesion uptake reached plateau levels by 20-30 min post-injection with SUVmax of up to 50. Maximal lesion uptake was seen in liver disease. For normal parenchymal tissues, the highest SUV at 30 min and 60 min post-injection were observed in kidneys, followed by liver and spleen. The highest absorbed dose estimates (mGy/MBq) to normal tissues were: urinary bladder wall (0.30± 0.06), kidneys (0.050± 0.013), liver (0.023± 0.014), lungs (0.021± 0.05), heart wall (0.020± 0.04) and spleen (0.016± 0.05). The effective dose was 0.025± 0.004 mSv/MBq. **Conclusion:** 68Ga-DOTA-JR11 demonstrated rapid tumor uptake, high tumor/background ratios and rapid clearance from blood. The low background uptake in the liver is advantageous and may facilitate detection of liver metastases. The dosimetric data compare favorably with previously published data of ^{68}Ga-DOTATATE and ^{68}Ga-DOTATOC (M. Sandstrom et al. JNM 2013), e.g. kidney 0.093± 0.016 mSv/MBq (TATE), 0.082± 0.02 mSv/MBq (TOC) versus 0.050± 0.013 mSv/MBq (JR11).

OP-172

First experience using LMI1195 in patients with the suspicion of pheochromocytoma or paraganglioma

C. Rischpler[1], A. M. Schlitter[1], M. Herz[1], B. Yousefi[1], A. von Werder[1], R. Tauber[1], T. Maurer[1], K. Scheidhauer[1], S. Robinson[2], C. Orlandi[2], S. G. Nekolla[1], M. Schwaiger[1]; [1]Technical University Munich, Munich, GERMANY, [2]Lantheus Medical Imaging, N. Billerica, MA, UNITED STATES OF AMERICA.

Introduction: N-[3-bromo-4-(3-(18)F-fluoro-propoxy)-benzyl]-guanidine [LMI1195], a novel, F-18-labeled radiotracer for non-invasive PET imaging of the norepinephrine transporter expression has only been evaluated in healthy volunteers so far. The aim of this study was to investigate this radiotracer in patients with the suspicion of pheochromocytoma (PHEO) or paraganglioma (PARA). **Methods:** 8 patients with suspicion of primary PHEO or PARA, 1 patient with suspicion of recurrent PHEO and 1 patient with suspicion of recurrent PARA were imaged using LMI1195 PET. On average 256±33 MBq were injected and PET/CT imaging (Siemens Biograph mCT) was started 55±11 minutes p.i. (effective dose: 6.7±0.9 mSv, imaging time: 22±2 min). Any medication potentially interfering with LMI1195 accumulation was discontinued prior to the scan according to the EANM guidelines for MIBG imaging. **Results:** After LMI1195 application no adverse events were observed. The most intense tracer accumulations were (SUVmean, organs in descending order of intensity: thyroid (SUV 25±8), salivary glands (SUV 14±4), bladder (SUV 13±15), kidneys (SUV 13±5), pancreas (SUV 13±4), stomach (SUV 10±4), left ventricle (SUV 9±2), liver (SUV 5±2), small bowel (SUV 4±2), spleen (SUV 3±1) and lungs (SUV 2±1)). In 7 patients a PHEO and in 1 patient PARAs were suspected by PET/CT (SUVmax 25±19 and 13, SUVmean 12±9 and 10; healthy adrenals: SUVmax 13±4, SUVmean 8±2). Clinical diagnosis was histologically confirmed in the resected tissue in 4 patients (PHEO) and excluded in 1 patient (endocrine-inactive adenoma). In 2 patients operation is scheduled and in 1 patient (high suspicion of multiple PARAs) a follow-up scan is scheduled. In the remaining 2 patients, there was no abnormality in PET/CT. PET image quality clearly outperformed the known limited properties of MIBG SPECT despite a 50% shorter imaging time and a comparable radiation exposure. **Conclusions:** LMI1195, a novel F-18-labeled PET-tracer, is highly promising for the confirmation, exclusion and staging of tumors of the adrenal medulla or the sympathetic trunk and further potential applications (e.g. assessment of the sympathetic innervation of the heart) should be evaluated.

OP-173

68Ga-NODAGA-exendin-4 PET/CT for the localization of insulinomas: preliminary data from a prospective multicenter imaging study

M. Boss, Sr.[1], M. Buitinga[1], M. Brom[1], D. Wild[2], V. Prasad[3], P. Nuutila[4], A. Brouwers[5], F. Pattou[6], M. Gotthardt[1]; [1]Radboud University Medical Center, Nijmegen, NETHERLANDS, [2]University of Basel Hospital, Basel, SWITZERLAND, [3]Charite University Hospital of Berlin, Berlin, GERMANY, [4]University of Turku, Turku PET Centre, Turku, FINLAND,

[5]University Medical Center Groningen, Groningen, NETHERLANDS, [6]University Hospital, Lille, Lille, FRANCE.

Background: Insulinomas are usually small, single benign tumors. Surgery is the therapy of choice and precise preoperative anatomical localization of the tumor is essential. Imaging techniques like CT, MRI as well as somatostatin receptor (SSTR) imaging have limited sensitivity. The stable glucagon like peptide-1 (GLP-1) analog exendin specifically binds to the GLP-1 receptor (GLP-1R), which is markedly upregulated/overexpressed in insulinomas. 68Ga-DOTA-exendin-4 PET/CT has been shown to be feasible in detecting insulinomas. Replacing the chelator DOTA by NODAGA in the labeling process ensures higher specific activities, allowing imaging with sub-pharmacological peptide doses. We propose 68Ga-NODAGA-exendin-4 PET/CT as a promising new method for improved localization of insulinomas. We here present the first cases of a multi center prospective imaging study to evaluate the effectiveness of 68Ga-NODAGA-exendin-4 PET/CT. **Methods:** 7 adults aged 24-65 with biochemically proven hyperinsulinemic hypoglycemia were included. PET/CT images were obtained one and two hours after injection of (5-7 µg) 95-105 MBq 68Ga-NODAGA-exendin-4. Current standard imaging was performed in all patients, consisting of CT or MRI and SSTR PET imaging. **Results:** In 2 patients standard imaging as well as GLP-1R PET/CT were all negative. Single lesions in the pancreatic body of 3 patients, and 2 lesions in the tail of 1 patient were identified by CT/MRI imaging as well as by SSTR PET/CT. At corresponding locations, GLP-1R positive lesions were clearly visualized using GLP-1R PET/CT, with low background uptake. In 1 patient an insulinoma was identified using GLP-1R PET/CT and SSTR PET/CT, which was located below the uncinate process, protruding in or against the duodenal wall. This insulinoma was not detected by MRI. None of the patients experienced any adverse effects (no hypoglycemia, nausea etc.) The 5 patients in whom lesions were identified underwent surgery and imaging findings were confirmed histologically. **Conclusion:** These preliminary results indicate the proof of principle that a low peptide amount of 68Ga-NODAGA-exendin-4 can detect insulinomas without relevant adverse effects and suggest a possible valuable role for this new imaging method.

OP-174

AZEDRA® (iobenguane I 131) in Patients with Malignant and/or Recurrent Pheochromocytoma/ Paraganglioma (PPGL): Overall Tumor Response Assessment

D. A. Pryma[1], B. B. Chin[2], R. B. Noto[3], J. S. Dillon[4], L. Solnes[5], J. Jensen[6], T. White[6], N. Stambler[6], S. Apfel[6], V. Wong[6], C. Jimenez[7]; [1]Perelman School of Medicine at the University of Pennsylvania, Philadelphia, PA, UNITED STATES OF AMERICA, [2]Duke University, Durham, NC, UNITED STATES OF AMERICA, [3]Warren Alpert Medical School of Brown University, Providence, RI, UNITED STATES OF AMERICA, [4]University of Iowa Carver College of Medicine, Iowa City, IA, UNITED STATES OF AMERICA, [5]Johns Hopkins Medicine, Providence, RI, UNITED STATES OF AMERICA, [6]Progenics Pharmaceuticals, Inc., New York, NY, UNITED STATES OF AMERICA, [7]University of Texas M. D. Anderson Cancer Center, Houston, TX, UNITED STATES OF AMERICA.

Introduction: Pheochromocytoma/paraganglioma (PPGL) are rare neuroendocrine tumors that overexpress the norepinephrine transporter (NET) that can be molecularly targeted for tumor selective therapeutic drug delivery. AZEDRA, a high specific activity, proprietary Ultratrace® form of I-131 MIBG, has been developed for the treatment of MIBG-avid metastatic and/or recurrent and/or unresectable PPGL. **Methods:** MIBG avid patients with PPGL ineligible for curative surgery, failed prior therapy or not candidates for chemotherapy, and on a stable antihypertensive regimen for tumor-related hypertension, were enrolled. 71% of patients received at least two prior lines of therapy and 31% of patients had prior conventional, low specificity MIBG therapy. Patients received a dosimetric dose (111-222 MBq) followed by up to two therapeutic doses, each at 296 MBq/kg to a maximum of 18.5 GBq, approximately three months apart. The effects on objective tumor response (RECIST) were determined and correlations to the primary endpoint (proportion of patients with at least 50% reduction of all antihypertensive medications lasting ≥6 months), number of administered doses, and prior MIBG were investigated. **Results:** 68 patients received at least one therapeutic dose (full analysis; FA). 50 patients received two therapeutic doses (per protocol; PP). The primary endpoint was met by 25% (95% CI 16%-37%) of FA patients, and 32% (95% CI 21%-46%) of PP patients, achieving the pre-specified success criteria. 23% and 30% of evaluable FA and PP populations, respectively, achieved best confirmed tumor response of partial response (PR). 69% of FA patients and 68% of PP patients achieved best overall response of stable disease (SD). Of the primary endpoint responders 41.2% experienced a PR and 0% progressive disease (PD), whereas in the non-responders 17% and 6.4% of PR and PD were observed, respectively. Similar response rates were observed, whether the patients had prior conventional low specific activity I-131 MIBG treatment or not, in their overall tumor response of PR (21.1%, 24.4%) and SD (73.7%, 66.7%), respectively. The most common (≥50%) treatment-emergent adverse events (TEAEs) were nausea, myelosuppression and fatigue. No acute drug-related hypertensive crises were observed. **Conclusions:** Objective tumor response of AZEDRA has been demonstrated in a pivotal phase 2b study. The current results suggest that tumor response correlates to the primary endpoint, patients able to tolerate additional doses of AZEDRA may experience better response, and efficacy persists regardless of previous conventional, low specificity MIBG use. Taken together, AZEDRA exhibits anti-tumor effects as well as potentially improving the debilitating cardiovascular sequelae of malignant PPGL.

Cardiovascular System: Myocardial Function, Metabolism & Perfusion - From Preclinical to Clinical Practice

OP-175
The study of ^{18}F-FDG PET/CT imaging for myocardial "ischemic memory" in different degrees

Z. Na, X. Meng, Z. Bai, K. Zhang, G. Zhang, **X. Wang**; *The Affiliated Hospital of Inner Mongolia Medical University, Hohhot, CHINA.*

Objective: According to compare the change of glucose metabolism and ischemic range on ischemic myocardial under two conditions of fasting and feeding by using Micro-PET/CT ^{18}F-FDG imaging with the SD model of acute myocardial ischemia in different degrees, explore whether the"ischemic memory "correlats with the extent of myocardial ischemia and certify the time window of myocardial "ischemic memory". **Methods:** 100 male SD rats weighing 400 ± 50g. The model of acute myocardial ischemia was made by ligating the inferior one-third of left anterior descending coronary artery. According to different blood flow occlusion time, the SD model was randomly divided into mild ischemic group (ligation 10s, 30 rats), moderate ischemic group (ligation 10s, 30 rats) and the severe ischemic group (ligation 60s, 35 rats). All models were performed ^{18}F-FDG Micro-PET / CT imaging after 24 h,48 h and 72 h . we calculated the volume of the ischemic (VOI) and the Standardized uptake value (SUV$_{mean}$) to compare weather the scope of ischemic myocardium under two kinds of conditions were the same. **Results**: 1. Fast-Feed comparison group: model rats showed a "focal" myocardial ^{18}F-FDG uptake increased, the volume of myocardial imaging agent was 17.52 ± 1.14mm^3, the similar difference was observed in the same part of the model rats with the "focal" myocardium ^{18}F-FDG, and the defect volume of the myocardial imaging agent was 20.00 ± 2.85mm^3. 2. Ischemic 10s group, 30s group, 60s group after24h and 48h modeling successfully, the defect volume of the imaging agent in the left ventricular wall was 8.31 ± 0.67mm^3, 15.16 ± 0.65mm^3 and 20.15 ± 2.48mm^3, 5.38±0.51 mm^3, 5.05±1.34mm^3, 6.03±1.14 mm^3,respectively. Ischemic 10s group, 30s group, 60s group after modeling 72h successfully: For 10s group and 30s group, there has no abnormal imaging uptake of sparse area. By contrast, the defect volume of 60s group is 1.38±0.34 mm^3. The corresponding standard uptake value of the three groups was 4.64±0.85,4.85±0.74,4.66±0.90 respectively. The difference was statistically significant. **Conclusion:** The time window of myocardial "ischemic memory" was different in various degree of myocardial ischemia. As to myocardial ischemia in mild-moderate degree , the time window of myocardial "ischemic memory" can be prolonged to 48 hours. For severe degree , the time window of myocardial "ischemic memory" can be prolonged to 72 hours.

OP-176
Myocardial FDG imaging of oxidative damage underlying anthracycline cardiotoxicity

M. Bauckneht[1], F. Pastorino[2], A. Buschiazzo[1], A. Bellini[1], V. Cossu[1], A. Orengo[1], P. Piccioli[1], G. Caneva[1], L. Pellegrino[1], L. Emionite[1], S. Ravera[1], S. Morbelli[1], A. Rubartelli[1], M. Ponzoni[2], G. Sambuceti[1], C. Marini[3]; *[1]IRCCS AUO San Martino IST, Genova, ITALY, [2]G. Gaslini Institute, Genova, ITALY, [3]CNR Institute of Bioimages and Molecular Physiology, Milano, ITALY.*

Aim: Cardiotoxic effect of Doxorubicin (DXR) is at least partially related to the drug capability to impair cardiomyocyte mito-

chondrial activity through oxidative stress, that can be eventually followed by a late development of contractile dysfunction. We previously reported that the early acceleration of glycolytic flux, which can be documented as an increased left ventricular (LV) ^{18}F-FDG uptake might be considered as an epiphenomenon of DXR-related cardiotoxicity. On the other hand, we reported that in cancer cells, FDG selectively tracks the activity of a specific glucose metabolism located within the endoplasmic reticulum activated in response to the oxidative damage. In the present study, we aimed to verify whether the increased LV FDG uptake following DXR exposure might be related to oxidative stress and whether this potential biomarker of cardiotoxicity is reduced by drug delivery systems such as Liposomal-DXR administration (Lipo-DXR). **Materials and Methods:** Animal experiments were approved by the Italian Ministry of Health. Five week old female, athymic mice were injected with Neuroblastoma cells in the left adrenal gland as previously described. Subsequently, they were treated once with saline (n=5), Free DXR (Free-DXR 5 mg/kg, n=5) or commercially available Lipo-DXR (Caelyx, 5 mg/kg, n=5). All mice were fed under standard dietary conditions. FDG imaging was performed with a dedicated micro-PET system at baseline and one week after treatment. An operator unaware of mice treatment manually identified a volume of interest on the LV and implanted neuroblastoma (N). Average standardized uptake value (SUV) of both LV and N were measured. Mice were subsequently sacrificed to evaluate myocardial content of oxidized and reduced glutathione as well as NADPH/NADP ratio. **Results:** N-SUV significantly increased only in controls (from 0.93±0.1 to 1.2±0.1, p<0.05), while it remained relatively stable in both Free-DXR (from 0.98±0.2 to 1±0.1, p=ns) and Lipo-DXR treated groups (from 0.96±0.2 to 0.8±0.1, p=ns). On the other hand, LV-SUV remained relatively stable in saline (from 0.7±0.1 to 0.8±0.1, p=ns) and Lipo-DXR treated animals (from 0.7±0.1 to 0.9±0.1, p=ns). Conversely, Free-DXR significantly increased LV-SUV from 0.7±0.2 at baseline to 1.1±0.1 at PET2 (p<0.01) and caused an evident oxidative damage as documented by decreased myocardial content of reduced glutathione combined with an altered ratio of NADPH/NADP. **Conclusions:** The present data document the capability of FDG imaging to identify an oxidative damage of the LV myocardium exposed to Free-DXR. This response is at least partially prevented by drug delivery systems that, however, preserve anthracycline therapeutic potential.

OP-177

The added value on clinical impact of SPECT/CT MPI: a one year experience

M. L. De Rimini[1], G. Borrelli[1], G. Mazzarella[1], A. Russo[2], M. Bifulco[1], P. Muto[1]; [1]Nuclear Medicine Unit; AO Ospedali dei Colli - Monaldi, Naples, ITALY, [2]Cardiovascular Unit; Vanvitelli University of Campania, Naples, ITALY.

Introduction: Multimodality Imaging can improve accuracy in coronary artery disease (CAD) diagnosis and in the disease management algorithms. Purpose: to evaluate the added value and clinical impact of SPECT/CT Myocardial Perfusion Imaging (MPI).

Methods: Over a period of 1 year 3312 patients (pts), affected or suspected for CAD, underwent Stress/Rest MPI (GE-Discovery NM/CT 670, 16 slice). History of multivessel disease (MVD) in 875/3312 pts, treated with stenting. All pts underwent 6 months clinical follow-up (FU). Processing, on a Xeleris Workstation using Myovation cardiac software with ordered subset expectation maximization (OSEM), obtained images with iterative reconstruction with and without attenuation correction (IRAC/IRNC) and with NC filtered back projection (FBP). Head to head images comparison (Cedars-QPS) was performed. *P* <0.05 was considered significant. **Results:** MPI classified the following results: -Normal (pts: 1230/FBP; 1301/IRAC; 1200/IRNC); -Chronic Ischemia (pts: 728/FBP; 690/IRAC; 745/IRNC); -Mild to Moderate transient ischemia (pts: 754/FBP; 730/IRAC; 767/IRNC); -Severe transient ischemia (pts: 600/FBP; 591/IRAC; 600/IRNC). IRAC better discriminated normoperfusion and transient ischemia (<0.05). In mild-moderate ischemia, IRAC resized the stress perfusion defect extension: IRAC = <5% vs >5% in 75 pts at FBP and vs >5% in 128 pts at IRNC. Furthermore CT added, at IRAC images, the evidence of calcium scores/calcific atheromasia on the coronary vessels, respectively in the 35.3% of pts with normoperfusion and in the 42.1% of pts with mild/moderate ischemia. In the 875 pts with stenting MVD: 652/875 showed perfusion defects at MPI: -moderate ischemia in 257 and severe ischemia in 395 pts. In these pts the intrinsic metallic contrast at CT helped to match perfusion defects in specific pertaining to the stenting vessel. Moreover, in the limited field of view of the chest explored by the study, non-CAD disease findings were also obtained at CT consisting of: -Pulmonary nodules in 39 pts, later confirmed as carcinoma in 12 out of them; -Breast carcinoma: 5 patients, showing nodule/micro-calcifications at CT; - Pleural effusion: 57 pts; -Lung fibrosis : 28pts. **Conclusions:** SPECT/CT MPI can add essential information in known and suspected CAD. Thanks to perfusion and morphological correlation, it can better influence pts management or lead to prevent disease, with findings that should be taken into account by clinicians. Moreover, it can radically change the clinical approach extending the pathological scenario by defining pts with unsuspected non-CAD disease. In SPECT/CT approach, the separate CT analisys and fusion imaging (MPI/CT) are mandatory to implement the clinical outcomes of patients.

OP-178

Clinical value of myocardial perfusion imaging in patients with homozygous familial hypercholesterolemia

*J. Jiao, Q. Wang, T. Mou, L. Wang, H. Mi, **X. Zhang**; Capital Medical University affiliated Beijing Anzhen Hospital, Beijing, CHINA.*

Objective: To evaluate the features of myocardial perfusion imaging (MPI) in patients with homozygous familial hypercholesterolemia (HoFH) and the correlation between blood lipid profile and myocardial ischemia. **Methods:** Forty-two consecutive HoFH (21 female, mean age 14.8±8.4 y) patients, diagnosed by clinical and chromosome test, were performed stress and rest ^{99m}Tc-sestamibi (11.1MBq/Kg) SPECT MPI with a two-day protocol. MPI was visually analyzed by 17-segment and 5-score sys-

tem, summed stress score (SSS), summed rest score (SRS) was acquired, and summed difference score (SDS) which represents the degree and extent of myocardial ischemia, was calculated by SSS-SRS. Association between SSS, SRS, SDS and the lipid profile, which including total cholesterol (TC), low density lipoprotein cholesterol (LDLC), triglyceride (TG) and high DLC (HDLC) was analyzed. **Results:** Patients were divided into 3 groups according to age, group 1(n= 14, age <10 y, female 6), group 2 (n =14, age 10-18 y, female 6) and group 3 (n=14, age ≥19 y, 9 female). TC was 14.8±3.8 mmol/L and LDLC was 12.5±3.4 mmol/L. There were 24 (57.1%) patients with positive MPI (SSS>1) and positive MPI was found in more female (76.2%, 16/21) than in male (38.1%, 8/21) (χ2=6.22, p<0.05). More patients with positive MPI were found with increasing age (42.9% in group1, 57.1% in group 2 and 71.4% in group 3, respectively, P>0.05). Positive ATP stress test was observed in 12 patients (28.6%), and it was observed in more female (42.9%, 9/21) than in male (14.3%,3/21) (χ2=4.2, p<0.05). 63 (8.82%) myocardial ischemia (SDS≥1) segments were found, which was respectively distributed in myocardial regions supplied by left anterior descending branch (LAD) (n=38, 60.3%), left circumflex branch (n=5, 7.9%) and right coronary artery (n=20, 31.7%). SSS was positively correlated with age (OR 0.33, 95%CI 0.016-0.21, p=0.023) and HDLC (OR 0.37, 95%CI 0.50-3.57, p=0.110). SRS was positively correlated with HDLC (OR 0.60, 95%CI 1.6-3.97, p=0.0001). SDS was positively correlated with age (OR 0.34, 95%CI 0.010-0.17, p=0.029). Multivariate logistic regression analysis indicated that female was the only independent risk factor to predict positive MPI (OR 5.2, 95%CI 1.37-19.77, p=0.016). **Conclusion:** In HoFH patients, myocardial ischemia was associated with age and female was more likely to have positive MPI. Myocardial ischemia segments were more likely located in myocardial regions supplied by LAD. Preliminary study indicated that MPI was an effective and non-invasive method for detecting myocardial ischemia in HoFH patients.

OP-179

Segmental comparison of myocardial inflammation, area at risk, edema and irreversible tissue damage after acute myocardial infarction

C. Rischpler, U. Handwerker, R. Dirschinger, K. Kunze, H. Kossmann, S. van Marwick, T. Ibrahim, K. Laugwitz, M. Schwaiger, S. G. Nekolla; *Technical University Munich, Munich, GERMANY.*

Introduction: After acute myocardial infarction (AMI) diverse, partly interacting processes such as inflammation, edema and scarring take place in the heart. T2-weighted MRI allows the assessment of myocardial edema and is often used as a marker to determine the area at risk (AAR). The accumulation of FDG under fasting conditions after AMI is often interpreted as myocardial inflammation and first studies suggest that the extent of FDG uptake also corresponds to the AAR. Another important factor assessed by MRI is the late gadolinium enhancement (LGE) as a marker of irreversible tissue damage. The aim of this study was to directly compare different processes such as inflammation, edema, irreversible tissue damage and AAR after myocardial in-

farction by multimodal imaging using hybrid FDG PET/MRI and Tc-99m sestamibi SPECT. **Methods:** In 13 patients the AAR was determined by Tc-99m sestamibi SPECT with tracer injection prior to revascularization - the method of reference for the assessment of AAR. In addition, all patients received a FDG PET/MRI (Siemens Biograph mMR) under fasting conditions within the first week after AMI. The parameters AAR (MIBI SPECT), edema (T2-weighted MRI), inflammation (FDG PET) and irreversible tissue damage (LGE MRI) were directly compared in 72 segments in one central slice through the center of the infarction. **Results:** There was no significant difference in extent between the AAR (47±13%) and the edema (44±20%, p=0.68), while both AAR and edema were significantly larger than the LGE extent (31±14%, p<0.009 and p<0.02) and the FDG extent (30±11%, p<0.003 and p<0.009). No difference was observed between FDG and LGE extent (p=0.76). No correlation between edema and AAR was found (R=0.16, p=0.59), while the LGE extent was significantly associated with the FDG extent (R=0.55, p<0.05). Interestingly, the extent of edema correlated with the FDG extent (R=0.61, p<0.03) and the LGE extent (R=0.62, p<0.03). **Conclusion:** The average extent of edema estimated using T2-weighted MRI is in the same range as the AAR. However, the lack of correlation between edema and AAR and the association of edema with irreversible tissue damage and inflammation indicates that T2-weighted MRI should not be used for AAR assessment.

OP-180

Prediction of Functional Recovery After Primary PCI Estimating Myocardial Salvage in Early Gated SPECT

*R. Sciagrà, **R. Calabretta**, F. Linguanti, F. Tutino, A. Ciaccio; Nuclear Medicine, DECBS, University of Florence, FLORENCE, ITALY.*

The purpose of primary percutaneous coronary intervention (PCI) in acute myocardial infarction (MI) is to achieve myocardial salvage (MS). This parameter would be the ideal surrogate endpoint for assessing treatment effectiveness and as well be useful to predict the patient final functional outcome. Because the reference method for measuring MS requires myocardial perfusion imaging (MPI) after tracer injection before PCI, alternative approaches based on imaging performed later after PCI have been proposed, but none has gained wide acceptance in clinical routine. Since gated SPECT MPI is sometimes performed to assess infarct size (IS) after MI, we tested the hypothesis that by comparing functional and perfusion abnormalities early after MI it is possible to estimate MS and to effectively predict the left ventricular ejection fraction (LVEF) recovery at follow up. We studied 120 patients with acute MI, enrolled in protocols for primary PCI. Early (before hospital discharge) and follow-up (approximately 6 months) gated SPECT MPIs were performed to measure infarct size, MS and functional outcome. In particular MS was defined as the difference between segments with abnormal thickening (= stunned area = risk area) minus segments with abnormal perfusion (= final IS), both data expressed as percent of the total number of segments in the AHA model. LVEF was calculated using the QGS software. The risk area was 40 ± 25%, the IS 17.3 ± 16% and the MS 22 ± 19%. The early LVEF was

46.6 ± 11.6% and the late LVEF was 51.4 ± 11.6%, with 54 patients showing at least an increase > 5 LVEF units. According to ROC analysis, MS was able to predict LVEF recovery with an area under the curve (AUC) = 0.79 (p < 0.0001), and using a cutoff > 23% detected LVEF recovery with 74% sensitivity and 71% specificity. Conversely, the IS obtained an AUC = 0.53 (NS). This study demonstrates that MS assessed by a single early gated SPECT MPI can accurately predict LVEF evolution after primary PCI for acute MI. Our results support the use of this simple approach for estimating MS in clinical practice to predict patient outcome, and as a surrogate endpoint for evaluating the effectiveness of primary PCI for research purposes.

OP-181

Association of brain and cardiac glucose metabolism in patients with coronary artery disease and prior myocardial infarction

X. Lu[1], T. Mou[1], Z. Yang[1], H. Mi[1], Q. Wang[1], X. Xie[1], X. Li[2], M. Hacker[2], Y. Wei[1], **X. Zhang**[1]; [1]Beijing Anzhen Hospital, Capital Medical University, Beijing, CHINA, [2]Department of Biomedical Imaging and Image-guided Therapy, Medical University of Vienna, Vienna, AUSTRIA.

To evaluate the brain glucose metabolism (BGM) in patients with coronary artery disease (CAD) and the impact of myocardial viability and left ventricular (LV) functional parameters: (ejection fraction, LVEF, %), end diastolic volume (EDV, mL) and end systolic volume (ESV, mL) on BGM. **Methods:** Ninety-five consecutive patients (age 57±10.4 y, male 89) with CAD and prior myocardial infarction (OMI) (mean LVEF: 34±15%) who underwent ^{99m}Tc-sestamibi SPECT, ^{18}F-FDG PET/CT, and brain imaging were recruited in our study. Patients with Parkinson, Alzheimer disease and brain vascular disease were excluded. LV functional parameters by gated PET/CT were analyzed by QGS software and BGM determined by mean of standardized uptake value (SUV$_{mean}$) was analyzed by Scenium software. Furthermore, relationship between cerebellum BGM and age, insulin dose (intravenously), ^{18}F-FDG dose, blood glucose level at baseline and at injection of FDG, LV functional parameters, myocardial viability was analyzed by Pearson correlation analysis test. **Results:** BGM in cerebellum (SUV$_{mean}$) was significantly correlated with LVEF (r = 0.205, p<0.05), ESV (r = -0.217, p<0.05), and the extent of myocardial scar (%LV) (r = -0.296, p=<0.01). No significant correlation was found between BGM and age, insulin dose, blood glucose level at baseline and at injection, EDV, and the extent of myocardial viability. Multivariate analysis revealed that the extent of myocardial scar (%LV) (r = - 0.296, 95%CI -0.043-0.009, p<0.01) was the only independent predictor for cerebellum BGM. Thus, patients were divided into three groups according to the extent of myocardial scar (%LV): Group 1 (n = 35, scar < 10%), Group 2 (n = 25, scar 10-20%) and group 3 (n = 35, scar >20%). BGM was significantly different within three groups in all brain regions, including cerebellum, frontal lobe, temporal lobe, parietal lobe, occipital lobe and basal-ganglia region (all p value <0.01). Moreover, severe reduction of BGM (SUV$_{mean}$ < 4.0) was found in 57.9% (22/35) of patients in Group 3 and 13.2% (5/35)

of patients in Group 1 (p<0.0001). Age, insulin dose, and glucose level at baseline and at injection FDG did not differ among three groups (all p value >0.05). In addition, no significant difference of BGM was found in patients with severe (LVEF≤25%,n=33), moderate (25%<LVEF≤45%,n=38) and mild LV dysfunction (LVEF>45%,n=25). **Conclusion:** BGM was significantly correlated with ESV, LVEF, and extent of myocardial scar, and it was significantly decreased in patients with >20% of myocardial scar. These findings warrant further prospective investigations.

OP-182

Predictive and prognostic value of left ventricular mechanical dyssynchrony assessed by myocardial perfusion SPECT in asymptomatic patients under hemodialysis

F. Caobelli[1], C. Popescu[2], R. Laudicella[3], A. Comis[3], S. A. Pignata[3], R. Sara[2], C. Rossetti[4], Young AIMN Working Group; [1]University Hospital Basel, Basel, SWITZERLAND, [2]Niguarda Hospital, Milan, ITALY, [3]University of Messina, Messina, ITALY, [4]Niguarda Hospital, Milano, ITALY.

Introduction: Patients with end-stage kidney disease under hemodialysis have an increased risk of adverse cardio-cerebrovascular events. In these patients, myocardial perfusion scintigraphy (MPS) provides useful prognostic information at short-term follow-up. Left ventricular mechanical dyssynchrony (LVMD) has been proven to predict the onset of major adverse cardiac events (MACEs) at short-time follow-up in patients with chronic kidney disease. It remains unclear, whether the same prognostic value pertains also to patients under hemodialysis at longer follow-up. **Subjects & Methods:** Seventy patients under hemodialysis (duration range 1-8 years) with neither history nor symptoms of coronary artery disease (CAD) at the time of MPS were retrospectively evaluated. All underwent clinical evaluation and MPS with pharmacologic stress test with dipyridamole. MPS were reprocessed to derive LV ejection fraction (EF), perfusion scores (SSS and SDS), and LVMD [phase histogram bandwidth (PHB) and phase standard deviation (PSD)]. MACEs were assessed at ≥2-year follow-up (median 29 months) and defined as nonfatal myocardial infarction, hospitalisation due to cardiac symptoms, new developed ischaemia or coronary revascularisation. Statistical analysis was performed using univariate and multivariate analysis on clinical and scintigraphic data. The rate of MACEs was evaluated with Kaplan-Meyer curves and Log-Rank test. **Results:** MACEs were reported in 8 patients (11.4%). Two of 8 had a myocardial infarction and 6 of 8 underwent coronary revascularisation. At univariate analysis, a correlation was demonstrated between MACEs and PSD (p=0.02), PHB (p=0.01) and the presence of peripheral artery disease (p=0.04). At multivariate analysis, only PSD and PHB were proven independent predictors of MACEs (p=0.03 and 0.001, respectively). At survival analysis, patients with abnormal values of PSD (and PHB had a significantly shorter event-free survival (for PSD - Odd Ratio [OR] 16.8, 95% confidence interval (CI) 3.3 - 84.5, p<0.001; for PHB - OR 5.4, 95% CI 1.2 - 24.6, p=0.03, fig. 1). Perfusion scores were not proven to be predictors of the onset of MACEs (p=0.18 for SSS and p=0.20 for SDS, respec-

tively). **Conclusions:** In asymptomatic patients without known CAD under hemodialysis, LVMD is highly predictive of the onset of MACEs at ≥2-year follow-up. As perfusion scores failed to show a predictive value, a phase analysis on gated MPS should be routinely performed in these patients, in order to yield useful prognostic information.

OP-183

Comparisons of glucose metabolism and striatal DAT binding in PD patients with different subtypes

L. Li[1], *C. Jiang*[1], *P. Wu*[1], *J. Zhao*[2], *C. Zuo*[1]; [1]PET Center, Huashan Hospital ,Fudan University, Shanghai, CHINA, [2]Department of Neurology, Huashan Hospital ,Fudan University, Shanghai, CHINA.

Aim: Parkinson's disease (PD) is characterized by loss of dopamine transporter (DAT) and a unique metabolic brain network (PDRP). The tremor-dominant subtype (TD) differs from the akinetic-rigid (AR) subtype of PD in clinical course and prognosis. The pathophysiology mechanism underlying these differences remains largely unknown. This study investigated the differences in glucose metabolic activity and striatal dopamine transporter (DAT) distribution between the two subtypes. **Materials and Methods**: Resting-state 18F-FDG PET imaging was performed in 136 patients with PD (including age and non-tremor scores-matched 75 AR-PD and 61 TD-PD) and 32 age-matched healthy controls. Among them, 100 PD patients (including age and non-tremor scores-matched 41 TD-PD and 59 AR-PD) and 17 age-matched healthy controls performed 11C-CFT PET imaging at the same time. For each 11C-CFT PET scan, sub-regional DAT binding was calculated for each hemisphere by the striatal-to-occipital ratio, defined as (striatum-occipital)/occipital counts, and these values were averaged across hemispheres. The expression of PD-related pattern (PDRP) was computed in each subject using a voxel-based network quantification algorithm based on the PDRP we previously identified in a cohort of 33 PD patients and 33 healthy controls. Comparison of regional metabolism was made on a voxel basis using SPM analysis, for which the scans from the PD patients with predominantly left-sided symptoms were flipped so that all subjects had the left hemispheres of the brain as their most affected side. Then a 4-mm radius spherical voxel of interest (VOI) centered at the peak voxel of clusters that was significant in the SPM analysis above was conducted to quantify regional cerebral metabolic rate of glucose (rCMRglc). Pearson correlation analysis was used to determine the relationship between rCMRglc and rest tremor scores. **Results:** The difference in 11C-CFT binding and PDRP scores between the TD-PD and AR-PD groups didn't show the significance by two-sample t test. Compared with AR-PD patients, TD-PD showed increased metabolism in bilateral cerebellum and left postcentral gyrus, and decreased metabolism in left medial frontal gyrus, left superior frontal gyrus and left cingulate gyrus. The rCMRglc in cerebellum demonstrated a positive correlation with rest tremor scores in TD-PD patients (P<0.05). **Conclusions:** The metabolism changes in cerebellum are related to rest tremor in PD, which maybe a clue to investigate the mechanism of tremor.

OP-184

Role of an artificial neural network classifier, a classification tree (CIT), to diagnose Parkinson's disease in early phase by using 123I-FP-CIT brain SPECT data

B. Palumbo[1], *A. Santonicola*[1], *S. Cascianelli*[2], *S. Nuvoli*[3], *M. L. Fravolini*[2], *M. Minestrini*[1], *M. Scialpi*[4], *N. Tambasco*[5], *A. Spanu*[3], *G. Madeddu*[3]; [1]Univ. of Perugia-Dept. of Surgical and Biomed. Sciences-Section of Nuclear Medicine, PERUGIA, ITALY, [2]Univ. of Perugia-Dept. of Engineering, PERUGIA, ITALY, [3]Univ. of Sassari-Dept. of Clinical and Experimental Medicine- Section of Nuclear Medicine, SASSARI, ITALY, [4]Univ. of Perugia-Dept. of Surgical and Biomed. Sciences- Section of Diagnostic Imaging, PERUGIA, ITALY, [5]Unit of Neurology- Perugia University Hospital, PERUGIA, ITALY.

Aim: To diagnose Parkinson's disease (PD) in early stage, we applied an artificial neural network classifier, a classification tree (CIT), that is composed of a set of logical rules organized as a decision tree to produce an optimized threshold based classification of data, to provide discriminative cut-off values. We applied a CIT to 123I-FP-CIT brain SPECT semiquantitave data, to obtain cut-off values of radiopharmaceutical uptake ratios in basal ganglia with the aim to classify PD versus other conditions. **Methods:** 123I-FP-CIT brain SPECT (Millenium VG, G.E.M.S.) was performed using semiquantitative analysis with Basal Ganglia (BasGan) V2 software according to EANM guidelines in 172 patients with mild movement disorders; 105 out of the 172 resulted as PD [56M and 49 F; range of age: 60-83 yrs, Hoehn and Yahr score (HY): 0.5-1.5; Unified Parkinson Disease Rating Scale (UPDRS) score: 6-38] and 67 resulted as non-PD (Essential Tremor and drug-induced PD, 33 M and 34 F; range of age 60-82 yrs). The final diagnosis was confirmed by a clinical follow-up of at least 6 months. A 10-fold cross validation was applied by repeating 1000 random experiments. This allowed the statistical evaluation of the "average performance" of CIT. **Results:** The probability of correct classification in patients obtained by CIT was 85.18±11.91% (mean±SD) for PD and 93.34±6.54%.% for non-PD patients. According to CIT, the first decision rule gave a value for the right putamen (RP) of 2.35±0.16, thus meaning that if RP values were lower than 2.35 patients were classified as PD, while if RP values were higher than 2.35 patients were classified as non-PD. To complete the classification performance, more complex CIT structures were tested, including also caudate nuclei and left putamen values as features, but they resulted as less significant. **Conclusion:** CIT allowed to accurately identify PD patients in early phase by using 123I-FP-CIT brain SPECT data and provided also reliable cut-off values able to classify PD and non-PD subjects. RP uptake values were the most discriminant and significant, probably due to a certain number of patients with initial prevalence of left clinical symptoms.

OP-185

Comparison of machine learning and semi-quantification approaches for DaTSCAN classification

J. Taylor; Sheffield Teaching Hospitals, Sheffield, UNITED KINGDOM.

Introduction: Semi-quantification and subsequent comparison with normal ranges is used routinely for objective [123I] FP-CIT (DaTSCAN) analysis. This approach is recommended by EANM clinical guidelines. Recent research has suggested that machine learning tools may be more accurate than conventional semi-quantification methods in binary image classification of DaTSCAN images into diseased or healthy groups. However, direct comparison between techniques is lacking. The aim of this study was to: • Compare the classification performance of 3 established machine learning approaches and 3 conventional semi-quantification methods using data from the Parkinson's Progressive Biomarkers Initiative (PPMI) database **Methods:** Images from 209 healthy controls and 448 patients with Parkinson's Disease were downloaded from the PPMI website (www.ppmi-info.org/data). **Machine learning algorithms:** A Support Vector Machine classifier was separately trained with three different sets of image features: 1) Image pixel intensities 2) Principal components of image pixel intensities 3) Striatal binding ratios (SBRs) from the putamen and caudate. Both linear and non-linear classifiers (using a radial basis function kernel) were considered. **Semi-quantification algorithms:** SBRs in the left and right putamen only were considered. Images with SBR results below normal limits, on either side of the brain, were classified as abnormal. Limits were set based on 3 different methods: 1) Linear regression of control data against patient age (95% confidence interval) 2) Mean of SBR results for age-matched controls (+/- 5 years, 95% confidence interval). 3) Minimum of SBR results for age-matched controls (+/- 5 years). Each machine learning and semi-quantification technique was evaluated using 5 fold cross-validation, repeated 5 times. **Results:** For the machine learning algorithms, the maximum mean accuracy using image pixels as features was: 0.96 (+/-0.01), using principal components as features was: 0.97 (+/-0.01) and using SBRs as features was: 0.96 (+/-0.02). For the semi-quantification methods mean accuracy using limits based on linear regression was: 0.94 (+/-0.02), using mean SBR was: 0.93 (+/-0.02) and using minimum SBR was: 0.90 (+/-0.03). **Conclusion:** This study provides evidence of the superior performance associated with machine learning algorithms, as compared to conventional semi-quantification analysis for binary classification of DaTSCANs.

OP-186

Abnormal striatal DAT distribution and PDRP expression in patients with rapid-eye-movement sleep behavior disorder

P. Wu[1], C. Jiang[1], L. Li[1], J. Ge[1], H. Yu[2], J. Wu[2], C. Zuo[1]; [1]PET Center, Huashan Hospital, Fudan University, Shanghai, CHINA, [2]Department of Neurology, Huashan Hospital, Fudan University, Shanghai, CHINA.

Objective: Rapid-eye-movement sleep behavior disorder (RBD) is an important risk factor for synucleinopathies such as Parkinson's disease (PD) which is characterized by loss of dopamine transporter (DAT) and a unique metabolic brain network (PDRP). This study investigated the striatal dopamine transporter (DAT) distribution characteristics and cerebral glucose metabolism features in patients with RBD and compared these imaging measures with those in patients with PD. **Methods:** Age-matched 30 healthy controls, 37 polysomnogram-confirmed RBD patients and 87 PD patients with different severity (Hoehn-Yahr (H-Y) stage I: 23 cases, H-Y II: 44 cases, H-Y III~V: 20 cases) were recruited to perform ^{11}C-CFT and ^{18}F-FDG PET imaging at the same time. For each ^{11}C-CFT PET scan, sub-regional DAT binding was calculated for each hemisphere by the striatal-to-occipital ratio, defined as (striatum-occipital)/occipital counts, and these values were averaged across hemispheres. The expression of PD-related pattern (PDRP) was computed in each subject using a voxel-based network quantification algorithm based on the PDRP we previously identified in a cohort of 33 PD patients and 33 healthy controls. **Results:** DAT distribution in caudate, anterior and posterior putamen in RBD and PD group were significantly lower than healthy controls (P<0.001). Similar with that in PD, the striatal DAT decrease followed an antero-posterior gradient in RBD. Using the Mean-2SD of healthy controls as cut-off value, RBD patients were divided into RBD with normal uptake (RBD-N) group (19 cases) and RBD with abnormal uptake (RBD-Ab) group (18 cases). The striatal DAT distribution gradually decreased along the groups of healthy controls, RBD-N, RBD-Ab, PD at H-Y I, H-Y II and H-Y III~V. In contrast, PDRP expression in RBD and PD group were significantly higher than healthy controls (P<0.001) and gradually increased along the groups of healthy controls, RBD-N, RBD-Ab, PD at H-Y I, H-Y II and H-Y III~V. **Conclusion** RBD patients present an intermediate state in striatal DAT distribution and cerebral glucose metabolism between PD and healthy controls, which demonstrates that RBD is the predromal stage of PD. Decreased DAT distribution is accompanied by increased PDRP expression from RBD to PD, which deserves further study for useful biomarkers of early diagnosis of PD.

OP-187

Striatal and extra-striatal F-Dopa PET binding potential index related to age, gender, smoker status and Carbidopa premedication

S. Toch[1], S. Poussier[1], E. Micard[1], P. Marie[1], E. Guedj[2], A. Verger[1]; [1]CHU Nancy, Nancy, FRANCE, [2]Assistance Publique des Hôpitaux de Marseille, Marseille, FRANCE.

Introduction: ^{18}F-FDOPA Positron Emission Tomography (PET) has been approved to assess the integrity of the striatal dopaminergic system in Parkinson's disease. The purpose of this study was to evaluate ^{18}F-FDOPA PET striatal and extra-striatal uptake changes related to age, gender and Carbidopa premedication. **Methods:** One-hundred and ninety-eight any known neurodegenerative nor neuro-oncologic disorder patients, who performed a whole body ^{18}F-FDOPA PET among which 21 with Car-

bidopa premedication, were retrospectively included. Cerebral images acquired 90 minutes after 4 MBq/Kg of radiotracer injection were extracted from these whole-body PET. SPM analysis was performed using an adaptive template derived from the 198 patients included and available in this article. Then, striatal Binding Potential Index (BPI) were calculated, using the occipital cortex as reference. **Results:** An age-related decrease uptake in diffuse cortical areas and an increase uptake in occipital cortex and cerebellum were found (p=0.05, FWE). Patients with Carbidopa premedication showed a significant lower putamen BPI compared to patients without Carbidopa premedication (p<0.03). Then, considering patients without Carbidopa premedication, women presented a lower left putamen BPI than men (p=0.02). Furthermore, an age-related ^{18}F-FDOPA BPI decrease in caudate nucleus (p<0.02), and a constant age-related ^{18}F-FDOPA BPI increase in putamen (p<0.01) was observed. **Conclusion:** Changes in dopaminergic system are associated with age including striatal and extra-striatal modifications likely due to atrophy phenomenon. Carbidopa premedication is not associated with a better striatum BPI.

OP-188

Validation of a reliable and convenient PET protocol for striatal dopaminergic dysfunction imaging using ^{18}F-LBT-999

N. Arlicot[1,2,3], J. Vercouillie[1,2,3], K. Mondon[1,3], V. Gissot[1,2], S. Maia[1,3], L. Barantin[1,2,3], Y. Peltier[2,3], J. Cottier[1,2,3], J. Houeto[4], J. Deloye[5], D. Guilloteau[1,2,3], M. Ribeiro[1,2,3]; [1]Centre Hospitalier Universitaire, Tours, FRANCE, [2]Université François Rabelais, Tours, FRANCE, [3]UMR U930 "Imaging and Brain", Tours, FRANCE, [4]Centre Hospitalier Universitaire, Poitiers, FRANCE, [5]Laboratoires Cyclopharma, Clermont-Ferrand, FRANCE.

Purpose: Parkinson's disease (PD) and Lewy body dementia (LBD) are characterized by a degeneration of the presynaptic dopaminergic neurons. Tropane derivatives are well established ^{123}I-ligands for SPECT imaging of the presynaptic neuronal dopamine transporter (DAT). Nevertheless, DAT SPECT studies present some drawbacks and many efforts have been made to develop PET analogs either labelled with C-11 or F-18. We report here the results of the first human study using a new DAT PET radioligand labelled with fluorine 18, the ^{18}F-LBT-999. **Subjects & Methods:** Six PD patients (age: 69±7 y, Hoehn and Yahr stage: I-II) and 8 controls (age: 69±9 y) were enrolled. 90-min dynamic PET acquisitions after iv injection of ^{18}F-LBT-999 (3.6 MBq/kg) were performed. Venous samples were concomitantly obtained for metabolites analysis. Caudate nucleus (Cd), putamen (Pu) and cerebellum regions of interest (ROI) were defined over each T1 3D MRI. Binding potential (BP) using SRTM method and ratios obtained for a 10-min image acquired between 30 and 40 min pi were calculated for Cd and Pu with cerebellum as reference region. **Results:** No adverse events or clinically detectable pharmacologic effects were reported. The parent fraction of ^{18}F-LBT-999 in plasma was 80%, 60% and 40% at 15, 30 and 45 min pi, respectively. For control group, the values were for BP 6.30±1.17 and 6.75±1.17 and for ratios 5.01±0.68 and 5.40±0.73,

for Cd and Pu, respectively. For PD group, the mean±SD BP values were 3.97±1.32 and 2.72±1.51, and the ratios 3.76±0.82 and 3.12±0.80, for Cd and Pu, respectively. For both striatal structures, BP and ratios were significantly decreased for PD patients compared to control group (*p*<0.001). **Conclusion:** These kinetics and tracer metabolism parameters, obtained from a small group of subjects, indicated that a 10-min PET acquisition, between 30 and 40 min pi of ^{18}F-LBT-999, associated to a subsequent analysis using simple ratios between striatal nuclei and cerebellum, is reliable for DAT PET imaging in the brain, allowing excellent discrimination between early PD patients and healthy controls. Such imaging procedure with ^{18}F-LBT-999 might be convenient considering its translation into clinical routine. **Acknowledgments:** This study was supported by the French National Agency for Research ("Investissements d'Avenir" no. ANR-11-LABX-0018-01), IRON and by Cyclopharma Laboratories. We thank the technical of CERRP, the nursing staff of the Service de Médecine Nucléaire, and the CIC-IT, CHRU of Tours, for their assistance.

OP-189

Validation of (S,S)-[11C]-Methylreboxetine Positron Emission Tomography in Parkinson's Disease

J. Brumberg, J. Tran-Gia, C. Kesenheimer, G. Brandt, C. Lapa, J. Volkmann, A. Buck, S. Samnick, I. U. Isaias; University Hospital Würzburg, Würzburg, GERMANY.

Purpose: To evaluate the feasibility of (S,S)-[11C]-Methylreboxetine (MRB) PET for evaluation of noradrenergic brain networks in patients with Parkinson's disease (PD). We (i) performed a phantom study, (ii) estimated binding potentials using a two-parameter multilinear reference tissue model (MRTM2), and (iii) assessed the influence of demographic and clinical parameters on first in patient scans. **Subjects and Methods:** We investigated eight men and two women with idiopathic PD (age: 60.5±6.3 years; disease duration: 4.4±4.2 years; H&Y: 1-3 stage; levodopa-equivalent daily dose (LEDD): 506±181mg) in medication-off condition (12h washout of antiparkinson medication). All subjects performed a MRI and a dynamic MRB-PET scan of 120min duration. In one instance, a 100-ml phantom filled with MRB-water-solution was placed inside the scanner to observe the noise characteristics of the PET imaging protocol. PET images were motion-corrected and co-registered to the individual's MRI images. After MRI-based normalization, several cortical and subcortical volumes of interest (VOI) were defined and transformed to the individual's PET space. VOI-specific time-activity curves were generated for scan durations of 40, 60, 80 and 100min (starting at t*=20min). MRTM2 served to calculate time-dependent non-displaceable binding potential (BP_{ND}) estimates of selected brain regions. Linear regression analysis was used to explore the association between BP_{ND} estimates with different scan durations and Spearman's rho to describe the correlation of BP_{ND} with demographic and clinical parameters. **Results:** The phantom study revealed a decay-induced coefficient of variance >20% for a scan-time of 120min, suggesting a trade-off between an adequate time coverage of the bioki-

netics and the minimization of the noise enhancement induced by later time points. Regional 80min BP_{ND} estimates exhibited a significant linear correlation with 60min BP_{ND} (R^2=0.90, p<0.001) and 100/40min BP_{ND} (R^2=0.74/0.72, p<0.001). Thalamic (p<0.01) and brainstem BP_{ND} (p<0.05) showed a negative correlation at 100, 80 and 60min scan duration with age only. **Conclusion:** Our results indicate that a 60min acquisition from 20 to 80min p.i. yields reliable estimates of BP_{ND} of MRB in PD patients. A reduction in scan duration greatly facilitates the use of this ligand in patients with advanced PD, which are unable to endure a two-hour acquisition. Also of relevance, we did not find any effect of the dose of dopaminergic medication (i.e. LEDD) on MRB binding.

OP-190

PET imaging of mGluR5 with [18F]FPEB in Parkinson's disease

Y. Kang[1], B. He[1], A. Verma[2], C. Henchcliffe[1], P. J. Kothari[1], D. Schlyer[1], K. Schmidt[2], P. C. Chiao[2], S. Vallabhajosula[1], P. D. Mozley[1]; [1]Weill Cornell Medicine, New York, NY, UNITED STATES OF AMERICA, [2]Biogen Idec, Inc., Cambridge, MA, UNITED STATES OF AMERICA.

Objective: The interaction between receptor systems is an area of intense interest for the development of new therapeutic drugs and the metabotropic glutamate receptor type 5 (mGluR5) is a potentially important regulator of the most common excitatory neurotransmitter system in the brain. The objective of this study was to explore the possibility of a correlation between mGluR5 and Parkinson's disease using the selective mGluR5 PET probe [18F]-FPEB. This is the first known imaging study of its role in Parkinson's disease (PD) in humans and we compared patients to matched healthy volunteers (HVs). **Methods:** The sample consisted of 9 patients with PD and 8 HVs. Dynamic images of the brain were acquired after the IV administration of ~183±13 MBq (~5 mCi) of [18F]-FPEB. Regions of interest (ROI) were placed with FreeSurfer on contemporaneously acquired MRI scans for the following regions: thalamus, caudate, putamen, hippocampus and amygdala. For comparison between PD patients and HVs, non-displaceable binding potential (BP_{ND}) values were calculated by the Logan reference tissue model using cerebellum white matter as the reference region. **Results:** With [18F]-FPEB, in overall brain regions, PD patients showed higher BP_{ND} values than HVs. In regional analysis, while PD patients did not show a significant difference with HVs in the caudate (9% enhancement, p=0.51), we found a significant enhancement of binding in the putamen (22% enhancement, p=0.05). In addition, hippocampus showed high enhancement but slightly less statistical significance was found (21% enhancement, p=0.06). Studies of dopamine transporter binding potential carried out on these same subjects using [11C]-PE2i showed a significant reduction in putamen (66% reduction, p<0.001) and caudate (49% reduction, p<0.001). **Conclusion:** The significant enhancement of binding of the radiotracer in the Parkinson patients when compared to the healthy controls indicate that the response to dopaminergic denervation in Parkinson's disease is mediated in part by the mGluR5 system.

Comparison of FDG PET/MRI and FDG PET/CT in Pediatric Oncology: Gazi University Pediatric PET/MRI Experience

L. Ö. Atay Kapucu[1], L. Uslu Beşli[2], Ü. Ö. Akdemir[1], U. Aydos[1], M. Özçelik[1], F. G. Pınarlı[3], A. Okur[3], N. I. Karabacak[1], C. Karadeniz[3]; [1]Gazi University Medical Faculty, Department of Nuclear Medicine, Ankara, TURKEY, [2]Istanbul University Cerrahpaşa Medical Faculty, Department of Nuclear Medicine, Istanbul, TURKEY, [3]Gazi University Medical Faculty, Department of Pediatric Oncology, Ankara, TURKEY.

Aim: Pediatric patients are one of the most important indications for FDG PET/MRI, due to reduced ionizing radiation. The aim of our study is to compare FDG PET/MRI and FDG PET/CT in terms of anatomical correlation of FDG positive lesions. **Materials and Methods:** Among 47 pediatric oncology patients, that have been referred to our department for FDG PET imaging, total 34 patients (mean age: 10,6±4,4), who had both PET/MRI and PET/CT imaging performed sequentially on the same day, and/or who had additional diffusion weighted MRI images were included in our study. Following mean 3,0±1,6 mCi (111±59 MBq) iv FDG injection, PET/CT imaging (GE Discovery ST) was performed first to 25 patients in median 73 minutes and PET/MRI (GE Signa PET/MRI) was performed first in the remaining 5. Sequential PET/MRI and PET/CT imaging was performed to total 30 patients. In addition to routine T1 weighted (T1W) and T2 weighted (T2W) imaging, diffusion weighted imaging (DWI) and ADC mapping were obtained in 16 patients. Anatomical evaluation and correlation of all FDG positive lesions were performed by 2 nuclear medicine physicians separately (scoring scale:1-3, 1: negative, 2: indeterminate, 3: positive). **Results:** Sixteen sequential PET/MRI and PET/CT images were FDG negative concordantly. Total 47 FDG positive lesions (maximum 5 lesions/patient) were found in the remaining 18 sequential PET/MRI and PET/CT images; 37 of them (78,7%) were positive with CT and 46 (97,9%) were positive with at least one MRI sequence. Out of 11 discordant FDG positive lesions, 10 (2 central nervous system (CNS), 4 bone marrow, 2 lymph nodes, 2 soft tissue lesions) could not be differentiated using CT although it could be demarcated using MRI. When T1W, T2W and DWI images were evaluated separately for all FDG positive lesions, 88,6% (39/44) of the lesions were positive with T1W, 88,9% (40/45) were positive with T2W and 96,9% (31/32) were positive with DWI. Among 16 PET/MRI images with additional DWI sequences, no correlation was found between ADC and SUV values, although FDG positive lesions showed diffusion restriction on visual analysis. **Conclusions:** PET/MRI showed better anatomical correlation in FDG positive lesions compared to PET/CT in our pediatric patients. When lesions were separately evaluated, PET/MRI had better anatomical correlation in bone marrow lesions, CNS tumors, lymph nodes and soft tissue mass. Due to reduced ion-

izing radiation and better contrast resolution in soft tissue and bone marrow, FDG PET/MRI could be preferred to PET/CT in the pediatric population.

OP-192

Positive & negative predictive value of FDG PET/CT in pre-therapy assessment of Bone Marrow infiltration in pediatric lymphoma patients

M. A. Abdelwahab[1], S. A. Badr[1], M. H. Kotb[1], H. Mostafa[2]; [1]National Cancer Institute, Giza, EGYPT, [2]NEMROCK, Cairo University., Giza, EGYPT.

Objectives: to explore the Positive and negative predictive value of FDG PET/CT in assessment of bone marrow infiltration in pediatric lymphoma patient at presentation. **Methods:** 140 pediatric patients with pathologically proven lymphoma [113 Hodgkin's disease (HD), 27 non- Hodgkin's lymphoma (NHL)] were enrolled in this study. All patients had pre-therapy FDG PET/CT and bone marrow biopsy within duration not exceeding two weeks. Clinico-pathological and other radiological data were extracted from patients' files. **Results:** Among the 140 lymphoma patients FDG PET/CT revealed positive BM involvement in 41 patients with two of them were false positive with negative BMB & regional MRI results. PPV was 95.1 % for PET/CT compared to 100 % with BMB. On the other hand None of patient has positive BMI by BMB & negative FDG PET/CT for BM infiltration, on the contrary the BMB missed 25 (17.9 %) patients with statistically significant difference as regards the NPV that was 100 % with PET/CT compared to 80.2 % with BMB (P<0.05). FDG PET-CT upstaged 17.9 % of the enrolled patients. **Conclusion:** FDG PET/CT seemed to be a promising modality with optimum Negative predictive value in assessment of BMI at initial assessment of pediatric lymphoma. Also, its high sensitivity has appreciable role in upstaging cases missed with BMB.

OP-193

Grading and outcome prediction of pediatric diffuse astrocytic tumors with diffusion and arterial spin labeling perfusion MRI in comparison with 18F-DOPA PET Grading and outcome prediction of pediatric diffuse astrocytic tumors with diffusion and arterial spin labeling perfusion MRI in comparison with 18F-DOPA PET

G. Bottoni[1], D. Tortora[2], A. Piccardo[1], M. Puntoni[3], M. Severino[2], P. Nozza[2], S. Mascelli[2], A. Raso[2], A. Verrico[2], M. Garrè[2], A. Rossi[2], G. Morana[2]; [1]E.O. Ospedali Galliera, Genia, ITALY, [2]Istituto G. Gaslini, Genova, ITALY, [3]E.O. Ospedali Galliera, Genova, ITALY.

Introduction: The aim of this study was to investigate MRI derived diffusion weighted imaging (DWI) and arterial spin labeling (ASL) perfusion imaging in comparison with ^{18}F-dihydroxyphenylalanine (DOPA) PET with respect to diagnostic performance in tumor grading and outcome prediction in pediatric patients with diffuse astrocytic tumors (DAT). **Methods:** We retrospectively analyzed 26 pediatric patients with histologically proven treatment naïve low and high grade DAT who under-

went ASL and DWI performed within 2 weeks of ^{18}F-DOPA PET. Relative ASL cerebral blood flow max (rCBF max) and minimum apparent diffusion coefficient (rADC min) were compared with ^{18}F-DOPA uptake Tumor/Normal tissue (T/N) and Tumor/Striatum (T/S) ratios, and correlated with WHO tumor grade and progression-free survival (PFS). Statistics included Pearson's chi-square and Mann-Whitney U tests, Spearman's rank correlation, receiver operating characteristic (ROC) analysis, discriminant function analysis (DFA), Kaplan-Meier survival curve and Cox analysis. **Results:** ASL, DWI and ^{18}F-DOPA PET data were positively correlated. Significant differences in terms of rCBF max, rADC min and ^{18}F-DOPA uptake were found between low- and high-grade DAT (p≤0.001). ROC and DFA demonstrated that T/S and T/N values were the best parameters for predicting tumor progression (AUC 0.93, p<0.001). On univariate analysis all diagnostic tools correlated with PFS (p≤0.001), however on multivariate analysis, only ^{18}F-DOPA uptake persisted to be significantly associated with outcome (p≤0.03); a trend emerged for CBF max (p=0.09) and ADC min (p=0.08). The combination of MRI and PET data increased the predictive power for prognosticating tumor progression (AUC 0.97, p<0.001). **Conclusions:** DWI and ASL provide useful and complementary information to ^{18}F-DOPA PET for pediatric DAT grading. ^{18}F-DOPA PET parameters better correlate with progression free survival prediction. Combining MRI and PET data provides the highest predictive power for prognosticating tumor progression.

OP-194

FDG PET in response evaluation of bulky masses in paediatric Hodgkin Lymphoma patients enrolled in the Italian AIEOP LH2004 trial

E. Lopci[1], M. Mascarin[2], A. Piccardo[3], C. Elia[2], L. Guerra[4], E. Borsatti[2], A. Sala[4], A. Todisco[5], A. Todisco[5], P. Zucchetta[5], P. Farruggia[6], A. Cistaro[7], S. Buffardi[8], P. Bertolini[9], M. Bianchi[10], M. Moleti[11], F. Bunkheila[12], P. Indolfi[13], A. Garaventa[14], R. Burnelli[15]; [1]Humanitas Clinical and Research Hospital, Milano, ITALY, [2]Centro di Riferimento Oncologico, Aviano, Aviano, Pordenone, ITALY, [3]Galliera Hospital, Genova, ITALY, [4]Hospital San Gerardo, Monza, ITALY, [5]University Hospital, Padova, Padova, ITALY, [6]Ospedale dei Bambini, Palermo, Palermo, ITALY, [7]IRMET, Torino, Torino, ITALY, [8]Napoli – Pausillipon, Napoli, ITALY, [9]Azienda Ospedaliera, Parma, ITALY, [10]Regina Margherita, Torino, ITALY, [11]Università La Sapienza, Roma, ITALY, [12]Hospital San Salvatore, Pesaro, ITALY, [13]Napoli – 2° Università, Napoli, ITALY, [14]Gaslini Hospital, Genova, ITALY, [15]University Hospital S. Anna, Ferra, ITALY.

Aim: In the current report we illustrate the results concerning the role of FDG PET in response evaluation of bulky masses in paediatric Hodgkin's Lymphoma (HL) patients enrolled in the Italian AIEOP LH2004 trial. **Materials and Methods:** We analysed data derived from 703 patients (M:F=388:315; mean age 13 years) affected by HL and enrolled in 41 different Italian Centres from March 2004 till September 2012, all applying to the AIEOP-LH2004 protocol. The cohort comprised 309 patients with bulky masses, of which 238 were evaluated with FDG PET at baseline and after 4 cycles of chemotherapy. Response was determined

according to combined functional and morphological criteria. Patients were followed up for a mean period of 43 months and for each child we calculated time-to-progression (TTP), considering as reference standard clinical monitoring, instrumental and histological data. Statistical analyses were performed for FDG PET and morphological response with respect to TTP. **Results:** Overall, at response evaluation we defined 238 PET-negative (90.5%) and 25 PET-positive bulky masses (9.5%), which on log rank analysis showed a statistically significant difference in terms of TTP (p<0.0001): mean TTP of 32.67months for negative scans versus 23.8 months for positive cases. In the same cohort, the morphological response on CT showed a CR in 85 patients (32.3%), a PD in 6 patients (2.3%) and a PR in 165 cases (62.7%), which on log rank analysis for TTP resulted statistically significant: 31.1 months for CR, 7.9 months for PD (p<0.001). When specifically analysing the role of PET in PR patients, the modality could distinguish patients having different TTP (p<0.0001): PET negative 34.9 months versus 24.6 months for PET positive. **Conclusions:** After 4 cycles of chemotherapy, FDG-PET response assessment in paediatric HL with bulky masses is a good predictor of TTP and disease outcome. Moreover, in patients presenting with a partial response on CT, PET results capable of differentiating patients having a longer TTP.

OP-195
Usefulness Of FDG-PET/CT In Assessing Bone And Bone Marrow Involvement In Pediatric Hodgkin Lymphoma

P. Guglielmo[1], C. Dolci[2], A. Sala[3], M. Spinelli[3], F. Elisei[4], E. Turolla[5], C. Crivellaro[1], C. Landoni[1], L. Guerra[4]; [1]University of Milan Bicocca, Milano, ITALY, [2]Fondazione Tecnomed, ASST Monza - Ospedale San Gerardo, Milano, ITALY, [3]Fondazione MBBM, Monza, ITALY, [4]ASST - Monza, Ospedale San Gerardo, Monza, ITALY, [5]Fondazione Tecnomed, ASST Monza - Ospedale San Gerardo, Monza, ITALY.

Purpose/Introduction: Hodgkin Lymphoma (HL) is a highly curable pediatric cancer. 18F-FDG PET/CT has increasingly been introduced into guidelines and in clinical routine for staging coupled with bone marrow biopsy (BMB) to detect Bone Marrow Involvement (BMI) and stage IV of the disease. Nevertheless, PET/CT has been shown to be a sensitive diagnostic procedure for bone and BMI detection and can be more accurate than BMB. The aim of the study was to analyze the usefulness of 18F-FDG PET/CT in the assessment of BMI in staging of pediatric HL. **Subjects & Methods**: thirty-eight patients (17 females), mean age of 14.2 years (range 7.7-17.9) with histological diagnosis of HL and unilaterally trephine BMB performed at staging, were retrospectively included in the study. PET/CT studies were reviewed by 2 readers in consensus and PET/CT was considered positive if a focal uptake higher than physiological bone marrow activity was evident. **Results**: 6/38 (15.7%) patients presented with focal uptake indicating BMI, 3/6 (50%) without bone lesions at CT, 2/6 (33%) with lytic bone lesions and 1/6 (17%) with sclerotic bone lesions. In 5/6 (83%) follow-up imaging (MRI, CT or plan radiography) confirmed PET findings of bone/bone marrow involvement. In one patient with multifocal bone marrow disease at PET/CT no followup imaging was performed. Conversely, trephine BMB was positive only in 1/6 (17%)

patient with multiple focal tracer uptake at PET correlated to sclerotic bone lesions at CT. On the other side, FDG-PET/CT did not miss any patient with positive BMB. **Conclusion**: FDG PET/CT is a reference standard in the staging of Hodgkin Lymphoma. The high sensitivity of FDG-PET/CT for bone and bone marrow involvement has recently raised the issue regarding the need of a BMB and currently BMB is not mandatory when a FDG-PET/CT is performed. Although, the current study needs to be extended to a more consistent patients population, the preliminary data confirmed that PET/CT can be a valid approach to detect bone/bone marrow disease and BMB can be spared in pediatric HL.

OP-196
The Role of FDG PET/CT Metabolic Parameters In Predicting Metastatic Disease In Pediatric Osteosarcoma Patients and The Prognostic Importance

A. K. Fidan, G. Ucmak, I. Kerimel, B. E. Akkas, B. B. Demirel; S.B.U. Ankara Oncology Research and Training Hospital, Nuclear Medicine Department, Ankara, TURKEY.

Aim: Osteosarcoma is the most frequent seen primary bone tumor in pediatric patients. Metastasis is usually seen at the time of diagnosis or during follow up period. The 5-year survival of patients with local disease is about 70%, where as in patients with metastatic disease, survive rates significantly decreases to 20%. FDG PET/CT is a reliable diagnostic tool which gives important information regarding the extent of disease as well as patient prognosis. In this retrospective study, we aimed to investigate the potential prognostic role of metabolic parameters such as standardized uptake value (SUVmax), metabolic tumor volume (MTV) and total lesion glycolysis (TLG) of primary tumor in predicting distant metastasis in patients with osteosarcoma. **Method:** 37 patients with osteosarcoma (age range: 6-19 years) who underwent FDG PET/CT for initial staging and were treated with neo-adjuvant chemotherapy and surgical resection in our hospital were included in this study. After a mean clinical follow-up period of 35 months (range:4-89 months), all patients are retrospectively grouped as patient with local disease (LD) and patients with metastatic disease (MD). SUVmax, MTV and TLG levels of the primary tumorat the time of staging, were analyzed for the correlation of progressive disease and metastasis. The probability of predicting metastatic disease is investigated with ROC analysis. The association between metabolic parameters of primary tumor and progression rate of disease is analyzed by Mann Whitney-U-test. **Results:** SUVmax, MTV and TLG were significantly higher in MD compared to LD group (13.4 ±5.5, 494±342 ml and 2480±2392 gr vs. 7.9±2.8, 147±81 ml and 526±242 gr respectively,p=0.001). The cut-off values for SUVmax, MTV and TLG were 9.67, 236.5 ml, 940.5 gr, respectively. In ROC analysis, areas under curve were 82% for SUVmax, 96% for MTV, 99% for TLG. When metabolic parameters were analyzed for disease progression, we observed that TLG of the primary tumor was the only significant metabolic parameter in predicting disease progression in patients with localized disease. **Conclusion:** The metabolic parameters of initial staging PET/CT can predict progressive metastatic disease on follow-up in pediatric

patients with osteosarcoma with high sensitivity. We found that patients with high TLG have increased risk for progression even with localized disease at the time of diagnosis. Therefore, we considered that high metabolic parameters are associated with poor prognosis and may guide clinical management.

OP-197

Argentinean experience with the use of PET CT 18F DOPA in patient with suspected congenital hyperinsulinism

M. J. Bastianello[1,2]; [1]Instituto Universitario CEMIC, CIUDAD DE BUENOS AIRES, ARGENTINA, [2]Universidad Nacional de San Martin, Bs. As., ARGENTINA.

Purpose: To describe our initial experience in the use of PET / CT with 18F-DOPA for the diagnosis and differentiation of Hyperinsulinism (HIC) with focal versus diffuse pattern uptake. **Material and Method:** We studied 17 patients with clinical suspicion of HIC by administering 18F-DOPA (4.2 MBq / kg body weight) and acquiring late and early images of the abdomen and pelvis. The equipment used was a PET / CT Gemini 64 TOF. The SUV was calculated on coronal sections in regions of greater uptake of the head, body and tail of the pancreas. The SUV was calculated in a region of the baseline pancreas considered as baseline (SUVr). The SUV ratio of each region on the SUVr was obtained. If the ratio was greater than 1.5, the corresponding region was considered pathological, considering the case as focal HIC. Diffuse HIC was considered in cases where the uptake was homogeneous but with an SUV greater than 3. Normal studies were considered diffuse with an SUV of less than 3. A total of 17 patients with a mean age of 30 months +/- 49 (range 1-68 months) were studied. Those who were under 36 months of age were anesthetized to perform the study .The diagnosis with histopathological analysis and / or clinical follow-up was confirm in all Cases. **Results:** The quantification of the images showed evidence of pathological uptake in different areas according to the patients: 7 Diffuse (41.1%), 8 Focal (47.0%) and 2 Normal (11.7%). The focal points were distributed as follows: head (41.2%), neck (5.9%) and tail (5.9%) of the total number of studies. Patients with focal uptake had a mean age of 53.7 +/- 63 months versus 10.4 +/- 10 months in patients with diffuse uptake. Two of the patients with diffuse uptake and three with focal uptake did not respond to diazoxide. The genetic pattern was obtained showing an adequate concordance with the PET / CT study. In patients with focal ICH, a high correlation was observed between the anatomical region visualized as hypercaptive in PET / CT with 18F-DOPA and the surgical and anatomopathological findings. **Conclusion:** PET / CT with 18F-DOPA has allowed us to implement the international algorithms for the diagnosis of HIC with a high surgical and anatomopathological correlation.

OP-198

Lymphoscintigraphic anomalies in children with Gorham's disease

M. Pizzoferro, M. F. Villani, A. Jenkner, I. Rana, D. Barbuti, M. C. Garganese; IRCCS Bambino Gesù Paediatric Hospital, Rome, ITALY.

Purpose: Gorham-stout disease (GSD) is a rare disorder characterized by proliferating lymphatic tissue and massive osteolysis. The lymphatic malformations can arise in any anatomic location and complications are relative to interested district. Lymphoscintigraphic imaging allows assessment of the lymphatic component in bone and soft tissues showing failure of the lymph-conducting system in involved body site. The aim of this study was to investigate lymphoscitigraphic imaging findings of a group of patient affected by GSD and to evaluate the role of lymphoscintigraphy to highlight the injury to the lymphatic system in GDS. **Subject and Methods:** Four patients with confirmed diagnosis of GSD were evaluated by lymphoscintigraphy. Lymphoscintigraphy was included in the context of an extensive clinical and imaging work-up. Lower limb lymphoscintigraphy was performed in all patients by planar (dynamic, static, whole-body acquisition) and SPECT imaging up to 24h, according to a standard protocol. SPECT/CT-RMN evaluation was also performed. In one patient with humeral involvement an additional upper limb lymphoscintigraphy was performed. **Results:** In our series of four patients (1F, 3M), we studied two children (4 months, 6 years) with recent GDS diagnosis and two patients (15, 24 years) with stable disease followed by infants. Both patients with recent diagnosis had an involvement of the spinal cord and previous chylothorax: lymphoscintigraphy showed recurrence of pleural effusion and tracer stasis in the paravertebral site. Patients of follow-up group had multiple interested districts: lymphoscintigraphy showed tracer accumulation in the pelvis (female patient) and in soft tissue of left arm (patient with humeral involvement). In all patients with the exception of the newborn, lymphoscintigraphy at 24h showed presence of tracer accumulation in abdomen, corresponding to intestinal loops by fusion imaging evaluation. **Conclusion:** Our experience suggests that lymphoscintigraphy should be considered as a valuable imaging modality to investigate patients with GDS allowing a whole-body lymphatic mapping. It can be easily performed in newborns, infants and young adults without pulmonary embolism risk (even in patients with chylothorax). Our results highlight a potential application of lymphoscintigraphy in GDS diagnostic work-up (basal evaluation of lymphatic function, early diagnosis of pleural effusion in progress) and in follow-up (clinical evolution of disease and therapy response assessment). Hybrid imaging improves interpretation of lymphoscintigraphy in patients with thorax/abdominal tracer accumulation, even in newborns. Abdominal tracer stasis is an abnormal finding that could represent a preclinical detection of visceral involvement in GDS patients but further studies are needed to confirm this preliminary result.

Using an asymmetric energy window improves image quality in planar bone scans

J. F. Machado[1], S. K. Doshi[1], R. Smith[2], M. Evans[1], R. N. J. Graham[1], S. Redman[1], D. Little[1]; [1]Royal United Hospitals Bath, Bath, UNITED KINGDOM, [2]Auckland District Health Board, Auckland City Hospital, Auckland, NEW ZEALAND.

Purpose: Previous work has investigated the effectiveness of using an asymmetric energy window for planar bone scans using simulation (Ruddlesden et al, Medical Physics and Engineering Conference 2010) and phantom data (Ruddlesden et al, EANM annual congress 2011). These phantom studies concluded that the asymmetric window improved both the resolution and contrast-to-noise ratio when imaging objects with high scatter. The purpose of this study was to confirm this increased image quality in patients. **Method:** Ethical approval was given for this study. Each of n=58 patients had two scans: a standard scan using an energy window of 140keV ±10% and an asymmetric window of 140keV +10%, -7.5%, using dual-head gamma camera (Infinia Hawkeye, GE Healthcare). For each patient, three radiologists independently compared the two image sets and scored them as follows: 1: asymmetric better (clinically important); 2: asymmetric better (not clinically important); 3: neither preferred; 4: standard better (not clinically important); 5: standard better (clinically important). Scores from all radiologists were pooled. The following hypotheses were tested using the sign test: H0: scores of 1 or 2 are equally likely, compared to 4 or 5; H1: scores of 1 or 2 are either more or less likely than scores of 4 or 5. **Results:** The pooled counts of each of the scores were as follows: 1: 5 2: 88 3: 66 4: 15 5: 0 For the sign test, the scores of 3 (neither preferred) are not used; the test is whether the total of 93 scores of 1 or 2 (asymmetric preferred) is significantly different from the 15 scores of 4 or 5 (standard preferred). This resulted in p<0.00001. In 5 cases, the asymmetric window images were preferred with the difference being clinically important; there were no cases where the standard window was similarly preferred. **Conclusions:** This study has confirmed in patients the improvement in image quality suggested by the previous simulation and phantom studies. Using an asymmetric energy window resulted in images which were on average preferred by the radiologists, in some cases providing extra information which was judged to be clinically important.

OP-207

Semi-quantitative analysis in salivary glands scintigraphy: a contribution for technical validation

J. S. Vale[1], D. Neves[1,2], L. Pires[3], M. F. João[2], A. I. Ferrer[2], L. F. Metello[1,4]; [1]ESS – IPP, ATC & Curso Med. Nuclear, Rua Dr. Antonio Bernardino de Almeida, 400, 4200 – 072, Porto., Porto, PORTUGAL, [2]Diaton S.A. – Unidade de Leiria, Rua de Olhalvas, Pousos, 2400 Leiria. Portugal, Leiria, PORTUGAL, [3]Diaton S.A. – Unidade de Coimbra, Urb. Espírito Santo, Lote 2 Calçada do Gato 3000-199 Coimbra, Coimbra, PORTUGAL, [4]IsoPor-Azores, Dept. de Med. Nuclear e Imagiologia Molecular, Angra do Heroismo, I. Terceira – Azores. Portugal, Açores, PORTUGAL.

Introduction: The gold standard in Salivary Glands Scintigraphy (SGS) evaluation is visual analysis, with all that it implicates in terms of subjectivity and intra/extra personal variability. Combination of visual with semi-quantitative analysis (SQA) introduces an objective parameter and reduces variability. However, it is observed a lack of standardization in protocols and the inexistence of standard values to facilitate comparisons. **Aim:** It's aimed to define a protocol for SQA in SGS with the evaluation of two functional parameters: Radiopharmaceutical Uptake (UP) and Ejection Fraction (EF) after stimulation. Additionally, it tends to contribute for the establishment of reference values for UP in the Portuguese population. Background correction (BC) relevance has been assessed as well. **Subjects and Methods:** 33

patients (7 men and 26 women; mean age: 55.58±16.39 ranging from 26 to 80 years) were included in the study. 3 images were acquired p/patient (pre and post syringe and injection site) and a 25 minutes dynamic study (20seg/frame with stimulation at 20 minutes). Patients were fasting for 2 hours previously from the administration of 5-10 mCi of ^{99m}Tc. For SQA purposes, activity effectively administered were calculated. A composite image were generated from the maximum uptake frames. ROI's were delineated in all salivary glands and in the skull, for background correction and EF for each gland was calculated. **Results:** For parotid glands uptake, in patients considered normal by visual analysis (n=3) the mean uptake was 4.16±1.27 and 4.86±1.53% with and without BC respectively, In pathological cases (n=30) was 2.34±0.79 and 2.81±0.9. For submandibular glands, in patients considered normal (n=6), the mean uptake was 2.68±0.66 and 3.03±0.68 with and without BC and in pathological cases (n=27) was 1.60±0.67 and 1.96±0.74. For EF, in patients considered normal by visual analysis (n=30), mean EF was 64.87±10.35, 65.93±7.37, 50.20±9.97 and 51.93±8.83 for the right parotid, left parotid, right submandibular and left submandibular respectively. There was only one pathological case and the referred values were 25, 58, 21 and 16%. The remaining 2 patients were considered impossible to access, due to low uptake. **Conclusion:** SQA seems to be an objective and useful tool for in SGS interpretation. The UP values obtained confirm this statement as we can see that parotid and submandibular uptake is lower in pathological cases than in normal ones for all salivary glands. There is a considerable difference between data obtained with and without background correction enhancing the need of standardization of the protocol.

OP-208

Advanced method to reconstruct SPECT image from few number of projection data

Y. Yamaguchi[1], Y. Okura[2], M. Yamamoto[2]; [1]Hiroshima International University Graduate School, Higashihiroshima-shi, JAPAN, [2]Hiroshima International University, Higashihiroshima-shi, JAPAN.

Aim: SPECT images reconstructed from few number of projection data are deteriorated by several artifacts such as streak artifact in FBP or image distortion in OSEM. The aim of this study is to develop novel method for SPECT image reconstruction from few number of projection data where the image quality is equivalent to SPECT image reconstructed from normal number of projection data to shorten acquisition time of SPECT study. **Methods:** Projection data of 24 view (15-degree step) of IB-10 brain phantom with ^{99m}Tc and Shepp-Logan numerical phantom were acquired by GCA-7200(Toshiba, Japan). Projection dataset of 12 view (30-degrees) were extracted from the 24 view datasets. We developed image reconstruction method using interpolation in the sinogram for detector direction, and the asymmetric projection data acquisition method, where relatively large step angle could be employed and opposite side data is inserted each projection direction. In this study, as interpolation method, we used the linear interpolation method. As evaluation methods, we used NMSE (normalized mean square error) and %RMSU (% Root Mean Square Uncertainty) as image quality index and image noise index, respectively. **Results:** NMSE of IB-10 brain phantom images reconstructed from 12 views, 24 views and 24 views interpolated from 12 views were 0.04195, 0.01262 and 0.02198. NMSE of Shepp-Logan phantom images reconstructed from 12 views, 24 views and 24 views interpolated from 12 views were 0.02157, 0.004099 and 0.005970. Image quality (NMSE) of reconstructed images interpolated from 12 view to 24 view was better than 12 view reconstructed images in both IB-10 Brain phantom image and Shepp-Logan phantom image. %RMSU were 33.71 % for 12 view reconstructed image, 38.35 % for 24 view reconstructed image, 38.02 % for reconstructed image interpolated from 12 view to 24 view. %RMSU of the reconstructed image interpolated from 12 views to 24 views was almost same value as the reconstructed image of 24 view which was not interpolated. **Conclusions:** We developed advanced technique for reconstruction of SPECT image. Our method applies interpolation method to the sinogram for detector direction and for asymmetric acquisition in the orbit. Image quality of SPECT image was improved by the method developed in this study. Our method will contribute to shorten the acquisition time not only SPECT study but also PET study.

OP-209

Wireless Online Monitoring of Radiation Dose Rate of Radioiodine (I-131) Ablation Patients: Saves Staff's Doses and Resources

M. C. Lehtinen Gil Compte, P. H. Puhakka, K. Levänen, M. Honkanen, S. Myöhänen, J. Heikkinen; South Savo Social and Health Care Authority, Mikkeli, FINLAND.

Introduction: In our organization, radioiodine I-131 thyroid ablation patients stay in isolation until the radiation dose rate, to which they expose their environment, has fallen under 40 µSv/h at 100 cm distance. Previously, a radiographer entered the isolation room to check the dose rate the day following the administration day. If the dose rate had not fallen under the discharge limit, she had to repeat the measurement later and be exposed to more radiation. Our aim was to minimize the radiation burden of the staff by conducting dose rate monitoring with a new wireless online measurement system. We expect that it would reduce the number of times a radiographer needs to enter the isolation room, and also the length and consequently, costs of the isolation. **Subjects and Methods:** A wireless dose rate monitor was positioned into the isolation room beside the bed, approximately 100 cm from the patient's pelvic skin. The system sent dose rate data to a server every minute. Remote monitoring of the dose rate was possible from any device with internet access. Time-dependent dose rates were analyzed for 19 radioiodine I-131 ablation patients (dose 1031-3896 MBq) during their stay at the isolation. The results were compared with the isolation times of the old system (11 patients, 2236-4026 MBq). **Results:** The new system reduced the number of times the radiographer entered the room during the isolation from average of 1.2 times to 1 time per patient. Reduction in average radiographer dose was estimated to be 2 µSv per pa-

tient. Average isolation time was reduced from 30h to 27h. The mean dose rates at the time of discharge with the old and new systems were 18 μSv/h and 20 μSv/h, respectively. Evaluated with the new system, the 40-μSv/h discharge limit was usually reached during the night, after 12.8 hours of isolation and the patients were discharged 1.3-25.4 hours (mean 13.9h) after reaching the discharge limit. **Conclusion:** Most importantly, the wireless system reduced the work load and the radiation exposure of the radiographer. Furthermore, the total isolation time was reduced, which saves the hospital resources. By studying the times of I-131 administration, reaching the discharge limit, and the realized and logistically optimal discharge, it is possible to optimize (in our case to postpone) the administration times. This could further reduce the isolation times, and consequently, reduce costs and the radiation exposure of the staff working close to the isolation room.

OP-210
The EU directive 2010/32, prevention from sharp injuries in the hospital and healthcare sector, in relation to ALARA: To recap or not?

A. F. Rekveld-van Moerkerken, K. Hart, F. Bomert, H. J. Verberne; Academic Medical Center (AMC), Amsterdam, NETHERLANDS.

Aim: The EU directive 2010/32 implies the use of safety needles. However these safety needles do not necessarily fit the sleeves used for the administration of radio-pharmaceuticals and require the needle to be removed before the syringe can be exposed of, possibly leading to higher radiation exposure. The aim of this study was to investigate if safety needles could be implemented without increasing the risk of contamination and without being exposed to a higher radiation dose. **Method and Materials:** Sixty syringes were filled with 100 MBq ^{99m}Tc-pertechnetate: thirty syringes had non-safety needles requiring a separate needle recapper and thirty syringes had safety needles. The syringes were injected into an empty vial with subsequent recapping of the needle. Thereafter, the needle and the syringe were separated and measured in a dose calibrator. Radiation exposure of the hand was calculated using the remaining dose in the needle and syringe, dose before injection, the distance from the source and the time needed to remove the needle from the syringe. In addition finger-dosimetry was assessed and radioactivity contamination was measured with a contamination monitor. **Results:** Contamination occurred once using the safety needles only (825 Bq/cm^2). The mean calculated hand dose with non-safety needles was lower compared to safety needles (0.16±0.01 μSv vs. 0.87±0.38 μSv, p <0.001). This difference was primarily driven by the time needed to remove the safety needles (4.9±1.1 seconds). These findings were corroborated by the results of the finger-dosimetry. In 2016 the total number of injections with ^{99m}Tc-labelled radio-pharmaceuticals at our department was 1658, resulting in a yearly hand radiation dose for the non-safety needles vs. safety needles of 267.20 μSv vs. 1438.79 μSv, respectively. Based on approximately 15 available workers this would have resulted in an averaged individual hand dose of 2.42 μSv vs. 13.02 μSv. **Conclusion:** The calculated radiation dose for ^{99m}Tc

using safety needles is more than 5 times higher compared to non-safety needles, primarily driven by the time needed to remove the safety needles from the syringe. However with safety needles the hand dose stays well below the maximum allowed dose (i.e. 500 mSv per year). Although there is a small risk of contamination using safety needles, this risk is most likely similar for non-safety needles. Our findings show that it is possible to use safety needles in combination with current protection sleeves without increasing the risk of contamination while staying well within the allowed exposure limits.

OP-211
The effect of PET scan time on the off-line PET image quality in proton therapy

H. Gunchul, J. joonyung, P. sejoon, C. eunsun, L. hyuk; Samsung medical center, seoul, KOREA, REPUBLIC OF.

Purpose: Proton therapy can deliver an optimal dose to tumor while reducing unnecessary dose to normal tissue as compared to the conventional photon therapy. As proton beams are irradiated into tissue, various positron emitters are produced via nuclear fragmentation reactions. These positron emitters could be used for the dose verification by using PET. However, the short half-life of the radioisotopes makes it hard to obtain the enough amounts of events. The aim of this study is to investigate the effect of off-line PET imaging scan time on the PET image quality. **Objectives and Method**: The various diameters of spheres (D=37, 28, 22 mm) filled with distilled water were inserted in a 2001 IEC body phantom. Then proton beams (100 MU) were irradiated into the center of the each sphere using the wobbling technique with the gantry angle of 0°. After 5 min of the proton irradiation, the PET/CT images of the IEC body phantom were obtained for 50 min. The PET images with different time courses (0~10 min, 11~20 min, 21~30 min, 31~40 min, and 41~50 min) were obtained by dividing the frame with a duration of 10 min. In order to evaluate the off-line PET image quality with the different time courses, the contrast-to-noise ratio (CNR) of the PET image calculated for each sphere. **Results**: The CNRs of the sphere (D=37 mm) were 0.43, 0.42, 0.40, 0.31, and 0.21 for the time courses of 0~10 min, 11~20 min, 21~30 min, 31~40 min, and 41~50 min respectively. The CNRs of the sphere (D=28 mm) were 0.36, 0.32, 0.27, 0.19, and 0.09 for the time courses of 0~10 min, 11~20 min, 21~30 min, 31~40 min, and 41~50 min respectively. The CNR of 37 mm sphere was decreased rapidly after 30 min of the proton irradiation. In case of the spheres of 28 mm and 22 mm, the CNR was decreased drastically after 20 min of the irradiation. **Conclusion**: The off-line PET imaging time is an important factor for the monitoring of the proton therapy. In case of the lesion diameter of 22 mm, the off-line PET image should be obtained within 25 min after the proton irradiation. When it comes to small size of tumor, the long PET imaging time will be beneficial for the proton therapy treatment monitoring.

OP-212
MOLY Project: a Mo-99 Production Program at ENEA TRIGA RC-1 Nuclear Research Reactor in Italy

F. Pisacane[1], O. Aronica[1], M. Carta[1], N. Cherubini[1], A. Dodaro[1,2], G. Giorgiantoni[1], M. Olivetti[1], E. Santoro[1]; [1]ENEA, Rome, ITALY, [2]Nucleo S.p.A., Rome, ITALY.

Due to the predicted ^{99m}Tc worldwide shortage, many countries are going to set up a method to produce this radioisotope, fundamental for many medical diagnostic practices. Aim of this work is to describe the feasibility of ^{99}Mo (which decays in ^{99m}Tc) production, starting from a ^{98}Mo(n,γ)^{99}Mo capture reaction through the irradiation of Molybdenum targets by using the TRIGA RC-1 nuclear research reactor (<u>T</u>raining <u>R</u>esearch <u>I</u>sotopes <u>G</u>eneral <u>A</u>tomic <u>R</u>eactor <u>C</u>asaccia <u>1</u>) in ENEA. The reactor's main features are: •Maximum power: 1 MW; •Maximum thermal neutron flux: 2.7×10^{13} $\mathrm{n \cdot cm^{-2} \cdot s^{-1}}$; •Core cooling by natural convection of demineralized water; •Irradiation facilities. To prove the possibility of achieving a significant specific activity after a suitable irradiation time, some preliminary evaluations have been performed on the basis of the following starting assumptions. 1.Metallic or sintered target of enriched ^{98}Mo. 2.Irradiation in the central channel of the core (3 cm diameter). 3.The cross-section of the capture reaction ^{98}Mo(n,γ)^{99}Mo for thermal neutrons is 136 mb. It is possible to increase this value by allowing for neutrons with energy in the resonance region. It is conceivable to assume an "effective" cross section $σ^*$, which takes into account the contributions related to intervals of the neutron spectra that include the epithermal and fast ranges. These contributions can be evaluated around 68% in the case of enriched ^{98}Mo and 78% for natural isotopic composition. Experiences in similar facilities show $σ^*$ values ranging from 400 - 500 mb up to 700 mb. 4.Total neutron flux composed by two components: the thermal component equal to 2.7×10^{13} $\mathrm{n \cdot cm^{-2} \cdot s^{-1}}$ and the fast one equal to 4×10^{13} $\mathrm{n \cdot cm^{-2} \cdot s^{-1}}$. 5.120 hours irradiation time, which corresponds approximately to two half-lives ($T_{1/2}$=66h) of the ^{99}Mo. The geometry of the central channel and the axial neutron flux of TRIGA RC-1 enable us to use, as far as the molybdenum samples are concerned, a section of 10 cm height in order to irradiate, from the neutron fluxes point of view, in most favorable conditions. In the central channel, several tens of grams of metallic molybdenum for each 120 hours session are supposed to be irradiated. As said before, a preliminary analysis confirms that, at the EOB (End Of Bombardment), it is possible to reach specific activity equal to about 30 GBq/g that could make possible a standard delivery of several radionuclide generators in health care units per week.

OP-213
F-18-FDG PET-CT Studies Reproducible Quantitative Assessment for Clinical Use

D. B. Faria[1,2,3], J. Teixeira[1,2], A. Martins[1,2], J. Fernandes[1,2], J. Pinto[1,2], J. Vale[1,2,3], J. Patrina[1,2], A. Roçado[1,2], D. Sousa[1,2], J. M. P. Oliveira[1,2]; [1]HPP - Medicina Molecular SA, Porto, PORTUGAL, [2]Lenitudes Medical Center & Research, Santa Maria da Feira, PORTUGAL, [3]School Of Health Sciences - University of Aveiro, Aveiro, PORTUGAL.

Recent improvements in PET hardware and software have been of extreme importance to reduce acquisition time, lower administered doses, improve image quality and offering new radiopharmaceutical uptake quantification possibilities. PET-CT Discovery LS (DLS) and PET-CT Discovery IQ (IQ) scanners, represent the range on Discovery BGO (GE Healthcare) clinical scanners, with improved sensitivity and count rate performances. Q. Clear™ (GE Healthcare) is a Bayesian penalized likelihood algorithm that includes a noise suppression term controlled by a penalization factor ß, that allows convergence for image quality and quantitation improvement over traditional iterative reconstructions algorithms. To ensure that data from longitudinal studies performed with these different scanners is interchangeable, it is necessary to define procedures to harmonize the quantification of SUV. **Aim:** to harmonize the quantification of PET/CT images performed with different scanner models at our department. **Methods:** A NEMA IEC Body Phantom, filled with a background activity of 6,61 and 3,72 kBq/mL and spheres with 34,312 and 19,19 kBq/mL, was scanned on a PET-CT scanner Discovery LS4 and a Discovery IQ 4 Rings for 12 minutes. DLS Images were reconstructed by OSEM (ordered subset expectation maximization) with 28 subsets, 2 iterations and IQ images with VUE Point HD (2 iterations, 24 subsets, and 6.4 mm filter) and Q. Clear β values between 50 and 500 with increment of 50. Circular volumes of interest were placed over spheres and background region, and voxel maximum activities were used to calculate recovery coefficients (RC) and contrast recovery coefficients (CRC) for all spheres. **Results:** DLS showed lower RC - 30,5% and 30,2% for the smaller sphere, reaching 107% and 102% for the 37mm sphere size; CRC ranged from 34% (smaller sphere) to 129% (biggest sphere). Images acquired with IQ, showed higher RC - 36% and 40% for VPHD reconstructions in smaller sphere size and higher CRC values, 17,9% and 22,4% for the smallest sphere and 113% and 115% for biggest sphere; Q. CLEAR reconstructed images showed a large variability in RC for smaller spheres, showing smaller RC values for higher β values; CRC showed the same tendency, with 78,4% and 82,9% for β50 and 18,3% and 25,4% for β500 for the 10mm sphere; increasing β value had less impact in RC and CRC for bigger sphere sizes. **Conclusion:** Clinical preliminary results show that harmonization for quantification in Nuclear Medicine Departments is possible and may reduce variability in quantitation if guaranteed the reproducibility of the methodology.

OP-214
Digital PET/CT in clinical routine: Dose reduction and image quality

J. Trinckauf, M. Hofbauer, M. Hüllner, I. Burger; University Hospital Zürich, ZURICH, SWITZERLAND.

Aim: With the installation of two digital PET/CT systems of the latest generation in our department, new dimensions of dose reduction and radiation protection are at hand. The possibilities offered by these new systems for dose reduction and whole body scanning have been implemented into the clinical routine. **Material and Methods:** Since January 2017, two identical GE DISCOVERY MI (DMI) PET/CT systems (64 slices CT) have been installed in our institute. For two months we had the analog DIS-

COVERY DSD PET/CT next to the new DMI for direct comparison. Due to the high detector sensitivity and the newest image reconstruction algorithms, we aimed for a reduction of the applied radiotracer dose. Based on an in-house developed BMI table, we determined the best possible dose reduction with maintained image quality with a substantial reduction for the DMI compared to the DSD PET/CT (4.5 MBq/kg): for BMI <20: 18F-FDG: 2.5 MBq/kg, BMI 20-24.5: 3 MBq/kg and BMI> 24.5: 3.5 MBq/kg. We also adapted the frame time according to dosage. While previously we acquired by default 2min / per bed position, we now acquire with 2.5min per bed position. The new scanner allows for one-stop whole-body acquisition in patients up to 2m body height. This is possible with a table extension, and patient repositioning for leg imaging is obviated. Using the reconstruction algorithm Q.clear, we were able to select different beta values for each radiotracer, yielding the optimal image quality. **Results:** Using the above mentioned BMI adapted ^{18}F-FDG dosing scheme an adequate image quality could be achieved in all patients on the DMI PET/CT compared to the higher doses on the DSD scanner with dose reduction of up to 45%. This also implies a considerable dose reduction for the technologist. The use of reconstruction algorithm Q. clear showed that an increase of the B-value is essential for lower doses. For the proposed BMI adapted ^{18}F-FDG dosing scheme an optimal value was determined at B = 450. A slightly increased (0.5min per bed position) examination time is well tolerated in clinical routine, and not inconvenient for the patient. The possibility of true whole-body examinations also facilitates clinical routine and simplifies patient preparation and positioning on the examination table. **Conclusion:** Digital PET / CT systems allow for significant dose reduction along with higher image quality.

Do.MoRe: PSMA Therapy

OP-215

Variation in the absorbed radiation dose and PSA response after serial Lu-177 PSMA radioligand therapy

C. Schuchardt, H. R. Kulkarni, S. Wiessalla, A. Singh, M. Shahinfar, D. Mueller, C. Lehmann, R. P. Baum; Zentralklinik Bad Berka GmbH, Bad Berka, GERMANY.

Aim: Prostate-specific membrane antigen (PSMA) is significantly over-expressed in prostate cancer cells. The aim of our study was to determine the inter-cycle dosimetry variation in patients with metastatic castration-resistant prostate cancer (mCRPC) undergoing at least 2 cycles of Lu-177 PSMA radioligand therapy (PRLT), in correlation with the change in serum PSA after PRLT. **Methods**: Dosimetry was performed during each PRLT cycle in 10 patients with mCRPC. PSMA expression was verified before therapy using Ga-68 PSMA PET/CT. Patients received at least 2 cycles of PRLT using 3.4-7.5GBq Lu-177 PSMA. The time-dependent biodistribution was determined based on whole-body scintigraphies and SPECT/CT. Dosimetric calcu-

lations (MIRD-scheme) were performed using OLINDA/EXM software. For intra-patient comparison, uptakes at 20h p.i. and mean absorbed doses were determined for kidneys and metastases. Variations between first and following therapy cycles were analyzed as mean with respect to the first therapy cycle (=100%). Serum PSA was determined before and every 4 weeks after the first PRLT cycle. **Results:** In 9 patients, all dosimetric parameters pertaining to metastases demonstrated variations between first and second therapy cycles: the mean uptake declined by 57% and the average dose by 64%. In contrast, the mean renal uptake increased by 62% and the average renal dose was therefore higher in the following cycles (34%), except for a lower renal dose at the second cycle in 1 patient (-17%). One of the patients showed inverse results, an increase in the tumor uptake (+84%) and dose (+154%) and a decrease in the renal uptake (-9%). However, the renal dose exhibited a mild increment (+19%). Patients with a fall in the absorbed tumor dose also demonstrated a biochemical response (decrease of serum PSA by 41%). The patient exhibiting an increasing PSA after the first cycle revealed a higher absorbed tumor dose during the second PRLT cycle. **Conclusions:** There is a significant inter-cycle variation of the absorbed tumor and kidney doses, which correlates with the change in PSA after PRLT. A decrease in serum PSA, indicating a therapy response, is therefore associated with a decrease in the absorbed tumor dose during subsequent PRLT cycle and vice versa. Whereas a decrease in tumor burden results in an increase in the absorbed renal dose due to an inverse sink effect. Administration of a higher amount of radioactivity in the first cycle seems to be reasonable, since the tumor doses tend to decrease in the subsequent cycles due to therapy Response.

OP-216

177Lu-PSMA-617 Treatment of Metastatic Castration-Resistant Prostate Cancer: Efficacy and Survival

E. Demirci[1], R. Akyel[2], O. Sahin[3], M. Ocak[4], A. Aygün[3], H. Pehlivanoglu[3], E. Karayel[3], L. Kabasakal[3]; [1]Department of Nuclear Medicine Sisli Etfal Training and Research Hospital, istanbul, TURKEY, [2]Department of Nuclear Medicine Umraniye Training and Research Hospital, istanbul, TURKEY, [3]Department of Nuclear Medicine, Cerrahpasa Medical Faculty, Istanbul University, istanbul, TURKEY, [4]Department of Pharmaceutical Technology, Pharmacy Faculty, Istanbul University, istanbul, TURKEY.

Aim: The aim of this study was to analyse efficacy of 177Lu-PSMA-617 Treatment in patients with Metastatic Castration-Resistant Prostate Cancer. **Materials and Methods:** 43 patients with metastatic castration-resistant prostate (mCRPC) cancer who underwent 177Lu-PSMA-617 treatment during period of 2014-2017 included in this retrospective study. Response to treatment evaluated according to follow up 68-Ga-PSMA PET/CT scans and weekly PSA levels. Progression-free survival (PFS) and overall survival (OS) rates were calculated according to first cycle of the treatment. **Result:** Patients were treated with an average dose of 21±7.2 GBq of 177Lu- PSMA-617. All patients had diagnosis of mCRPC with an average PSA level

of 264±108 ng/ml. 55,8% (n=24)of patients had lymph node metastasis,90,7% (n=39) of patients had bone metastasis and 18,6% (n=8) of patients had visceral organ metastasis. Grade 1 or 2 hematologic toxicity occurred in 26% (n=11) of patients and Grade 3 hematologic toxicity occurred in 7% (n=3) of patients. A decrease over 50% in PSA levels was observed in 23 (53%) patients. Among 28 patients who had a follow-up 68Ga-PSMA PET/CT 12 (27.9%) patients had progression, 16 (57.1%) patients had partial response. PFS, combined with serum PSA levels and available imaging modalities, calculated 6.5 months (%95CI:4-8,9). Median OS rate was calculated 15.9 months (95% CI: 13.1- 18.7) and 54.7 months (95%CI:51,7-58,1). In patients who had PSA decrease after treatment, OS was significantly higher compared to those who had increase (17.7 months %95CI:14,3-21,1 vs 13,8 months %95CI:10,1-17,6; p<0.05). **Conclusion:** 177Lu-PSMA-617 is a safe and effective treatment option in end-stage metastatic Castration-Resistant Prostate Cancer.

OP-217

Targeted Alpha Therapy of mCRPC: Dosimetry estimate of [213]Bismuth-PSMA-617

C. Kratochwil[1], K. Schmidt[2], F. Bruchertseifer[3], A. Afshar-Oromieh[1], A. Morgenstern[3], U. Haberkorn[1], F. L. Giesel[1]; [1]University Hospital Heidelberg, Heidelberg, GERMANY, [2]ABX-CRO, Dresden, GERMANY, [3]EC-JRC, Karlsruhe, GERMANY.

Purpose: PSMA-617 is a small molecule targeting prostate-specific membrane antigen. In this work we estimate the radiation dosimetry for this ligand labeled with the alpha-emitter [213]Bi. **Methods:** Three patients with metastatic prostate cancer underwent PET-scans 10min, 1h, 2h, 3h, 4h and 5h after injection of ^{68}Ga-PSMA-617. Source organs were kidneys, liver, spleen parotid and submandibular glands, urinary bladder, red-marrow and representative tumor lesions. The imaging nuclide ^{68}Ga was extrapolated to the half-life of [213]Bi. The residence times of [213]Bi were forwarded to the instable daughter nuclides. OLINDA was used for dosimetry calculation. Results are discussed in comparison to data for [225]Ac-PSMA-617. **Results:** Assuming a relative biological effectiveness of 5 for alpha-radiation, the dosimetry estimate revealed mean doses of 8.1 Sv/GBq for salivary glands, 8.1 Sv/GBq for kidneys and 0.52 Sv/GBq for red-marrow. Liver (1.2 Sv/GBq), spleen (1.4 Sv/GBq), bladder (0.28 Sv/GBq) and other organs (0.26 Sv/GBq) were not dose-limiting. Effective dose is 0.56 Sv/GBq. Tumor lesions were in the range 3.2-9.0 Sv/GBq (median 7.6 Sv/GBq). Kidneys would limit the cumulative dose to 3.7 GBq; red marrow might limit the maximum single dose to 2 GBq; thus, 3 cycles of 1.2 GBq might be a reasonable fractionation regime. **Conclusion:** Dosimetry of [213]Bi-PSMA-617 is in a range traditionally considered promising for clinical application. Nevertheless, the tumor-to-kidney ratio of [213]Bi-PSMA-617 is inferior compared to [225]Ac-PSMA-617 because the long half-life alpha-emitter [225]Ac can benefit from less perfusion-dependent off-target radiation and the shorter biological half-life of PSMA-617 in dose limiting organs.

OP-218

Overall survival and response pattern of castrated-resistant metastatic prostate cancer to multiple cycles of radioligand therapy using Lu-PSMA-617

H. Ahmadzadehfar, S. Wegen, A. Yordanova, R. Fimmers, S. Kürpig, E. Eppard, X. Wei, C. Schlenkhoff, S. Hauser, M. Essler; University Hospital Bonn, Bonn, GERMANY.

Introduction: Approximately 30% of patients with castrated-resistant prostate cancer (CRPC) do not show any response to the first cycle of radioligand therapy (RLT) with Lu-PSMA-617 (Lu-PSMA), measured as any decline in prostate-specific antigen (PSA). We evaluated patient response to the second and third cycles of RLT in patients that underwent at least three cycles. The second aim of this study was to calculate the median overall survival (OS) of responders and non-responders after the first cycle and after all three cycles of RLT. **Methods:** CRPC patients with distant metastases were treated with at least three cycles of Lu-PSMA, with a median interval of 8 weeks between each cycle. The tumour marker PSA was used as the main marker for response evaluation. **Results:** Fifty-two patients underwent a total of 190 cycles of RLT (3-6 cycles per patient). Of these, 80.8% showed a decline in PSA 2 months after the first cycle, with 44.2% showing a PSA decline of ≥ 50%. When compared to baseline PSA, 73.1% showed a PSA decline after the third cycle. Half (50%) of patients that did not show any response to the first cycle also did not respond to the second and third cycles. The median OS was 60 weeks. The median OS was significantly longer for patients that showed any PSA decline after the first cycle compared to patients without PSA decline (68 vs. 33 weeks). There was a significant difference in median OS between responders and non-responders for a change in PSA after the third cycle compared to baseline PSA. **Conclusion:** Patients with a positive response to RLT using Lu-PSMA (responders), regardless of the rate of decline, had a significantly longer median OS compared to non-responders. Of the patients that did not show any response to the first cycle, 50% did not respond to the second or third cycles.

OP-219

The impact of repeated cycles of Lu-PSMA-617 therapies on renal function in patients with hormone refractory metastatic prostate cancer

A. Yordanova, A. Becker, E. Eppard, S. Kürpig, C. Fisang, G. Feldmann, M. Essler, H. Ahmadzadehfar; University Hospital Bonn, Bonn, GERMANY.

Aim: Lu-PSMA-617 is a well-tolerated therapy for the treatment of metastatic prostate cancer. However, because of the mainly renal excretion of the tracer, the kidneys are one of the most limiting organs. The purpose of this study was to examine the post-therapeutic changes in renal function over time and to identify risk factors for developing renal toxicity. We also tested the reliability of markers for renal function monitoring. **Methods:** Fifty-five patients with castrate-resistant metastatic pros-

tate cancer treated with at least three cycles of Lu-PSMA-617 were investigated. Renal function was assessed through laboratory tests (creatinine, GFR, cystatin C) and Tc-99m-MAG3 measurements. Adverse events were classified according to the *Common Terminology Criteria for Adverse Events* (CTCAE) v4.0. To identify risk factors for renal toxicity, we used Pearson´s correlation coefficient and the corresponding p-values. **Results**: None of the 55 patients experienced severe nephrotoxicity (grade 3/4). In 14 patients (25%), we observed increased creatinine levels of CTC 1° or 2°. There were 16 cases of increased GFR (grade 1/2). At the baseline, only 14 patients had elevated cystatin C. However, post-therapeutic cystatin C was elevated in 32 patients (58%). A significant effect on renal function was found for age ($p = 0.049$), hypertension ($p = 0.001$) and pre-existing kidney disease ($p = 0.001$). The most reliable predictive markers of nephrotoxicity were TER-MAG3 and cystatin C. **Conclusion**: Renal toxicity in patients treated with Lu-PSMA-617 was low. There was no (sub)acute grade 3 or 4 nephrotoxicity.

OP-220

Lu-177 PSMA Radioligand Therapy might Prolong Survival in Metastatic Castration-Resistant Prostate Cancer: Results from a Single Center over 4 Years

H. R. Kulkarni[1], A. Singh[1], C. Schuchardt[1], T. Langbein[1], K. J. Pienta[2], R. P. Baum[1]; [1]THERANOSTICS Center for Molecular Radiotherapy, Bad Berka, GERMANY, [2]The Brady Urological Institute, Johns Hopkins University, Baltimore, MD, UNITED STATES OF AMERICA.

Purpose: Lu-177 PSMA radioligand therapy (PRLT) is currently a last line option in metastatic castration-resistant prostate cancer (mCRPC). This study aimed at evaluating the overall and progression-free survival in a large mCRPC patient cohort. **Subjects and Methods:** Between April 2013 and April 2017, intention-to-treat analysis was performed in 194 patients (mean age 71 years, mean Gleason score 8) with mCRPC, who were screened previously by Ga-68 PSMA PET/CT. They received 1 to 9 PRLT cycles (totally 545) using 3.5 - 10 GBq (mean 6.3 GBq) of Lu-177 labelled PSMA ligand. Previous treatments were surgery (169), external beam radiation (133), chemotherapy (96), androgen deprivation (194) and Ra-223 chloride (9). The most frequent sites of metastases were bone (148), lymph node (135), liver (25) and lungs (20), and 47 patients had diffuse bone marrow involvement. Ga-68 PSMA PET/CT was used for initial evaluation and therapy response assessment. Laboratory parameters including complete blood count, renal function and PSA levels were documented before and after therapy. **Results:** Any PSA decline was observed in 135/194 (69.6%) patients, best response was biochemical complete remission (PSA=0.0 ng/ml). Decrease in PSA by more than 50% was seen in 103 (53.1%) patients. Restaging with imaging (Ga-68 PSMA PET/CT) after at least 2 PRLT cycles in 136 patients demonstrated 6 complete remissions (5%), 70 partial remissions (51%), 11 with stable disease (8%) and 49 with disease progression (36%) according to molecular response criteria. Using RECIST 1.1, complete remission was observed in 4 (3%), partial remission in 41 (30%), stable disease in 52 (38%) and

progressive disease in 39 (29%) patients. Median overall survival was 34 months. Median progression-free survival was 13 months. There were no acute adverse effects. Mild xerostomia was reported by 9 (4.6%) patients. G3-4 hematological toxicity was observed in 9 (4.6%) patients, more frequently associated with disseminated bone marrow involvement, previous chemotherapy or Ra-223 treatment. **Conclusions:** Lu-177 PSMA radioligand therapy is a promising therapy option in mCRPC, with acceptable toxicity. An overall survival of 34 months and progression-free survival of 13 months despite extensive pretreatment, including chemotherapy, indicates that PRLT might potentially prolong the survival when compared with historical controls. However, prospective randomized control studies are needed to validate these results and to determine its place in mCRPC treatment.

OP-221

Targeted Alpha Radioligand Therapy (TART) using Bismuth-213 PSMA in End-stage Progressive Treatment-refractory PSMA-expressing Metastatic Prostate Cancer: Results of a Pilot Study

H. R. Kulkarni[1], A. Singh[1], T. Langbein[1], C. Lehmann[1], D. Mueller[2], S. Marx[3], K. J. Pienta[4], R. P. Baum[1]; [1]THERANOSTICS Center for Molecular Radiotherapy, Zentralklinik Bad Berka, Bad Berka, GERMANY, [2]Division of Radiopharmacy, Zentralklinik Bad Berka, Bad Berka, GERMANY, [3]ITG Isotope Technologies Garching GmbH, Munich, GERMANY, [4]The Brady Urological Institute, Johns Hopkins University, Baltimore, MD, UNITED STATES OF AMERICA.

Purpose: The feasibility, toxicity and efficacy of targeted alpha radioligand therapy (TART) using Bi-213 PSMA in end-stage metastatic treatment-resistant prostate cancer, having progressed under radioligand therapy using Lu-177 PSMA, were evaluated in a pilot study. **Subjects and Methods:** Bi-213 ($t_{1/2}$ 46 minutes) was obtained from a Ac-225/ Bi-213 generator (provided by ITG Isotope Technologies Garching GmbH), calibrated to elute 370 MBq of Bi-213 at the time of delivery. The labelling of PSMA-617 with Bi-213 was performed at the radiopharmacy of Zentralklinik Bad Berka. Between December 2016 and March 2017, we have treated 10 patients with Bi-213 PSMA (1-2 cycles, 2-4 applications per cycle). Extensive skeletal involvement was present in 7 patients, and 3 already suffered from G3-4 anemia and thrombocytopenia before TART. Of the 10 patients, 3 were retreated with a second cycle. The median administered activity of Bi-213 PSMA per cycle was 390 MBq (155 - 623 MBq). The very short half-life of Bi-213 necessitated at least 2 daily elutions of the generator, and 2-4 applications of Bi-213 PSMA to each patient per cycle over 2 days. Ga-68 PSMA-11 PET/CT (with contrast-enhanced CT) was used for patient selection and follow-up after TART. Response to therapy after 1 cycle was available at the time of analysis in 3 patients. Hematological status, renal function and serum prostate specific antigen (PSA) levels were documented before and after therapy. **Results:** All patients tolerated the therapy very well without any acute adverse effects; during follow-up there was no xerostomia and no additional hematological toxicity. Decrease in PSA was noted in 3/7 (43 %)

patients. Molecular response evaluation (Ga-68 PSMA-11 PET/CT) after 1 cycle of TART in 3 patients revealed stable disease/minor response, mixed response and progressive disease in 1 patient, respectively. Contrast-enhanced CT exhibited stable disease according to RECIST 1.1. One patient with disseminated bone metastases, already having received 9 cycles of Lu-177 PSMA therapy and progressing under additional 2 cycles of Bi-213 PSMA TART, died during the observation period. **Conclusions:** Targeted alpha radioligand therapy using Bi-213 PSMA is feasible in end-stage metastatic treatment-resistant prostate cancer, progressing after castration, newer hormonal agents, chemotherapy as well as after radioligand therapy using Lu-177 PSMA. With the administered radioactivities mentioned, no significant acute / subacute toxicity was noted and minor responses could be demonstrated. However, higher acitivities or more frequent cycles of Bi-213 PSMA might be required to achieve the desired response to therapy.

OP-222

Initial Theranostics Experience Using ^{68}Ga-PSMA-11 PET/CT and ^{177}Lu-PSMA-617 in a Chilean Oncology Center

H. Amaral[1,2], R. Fernández[1], V. Kramer[2], H. Lavados[1], E. Hernández[1], B. Morales[1], R. Pruzzo[1], A. Haeger[1], J. Ribbeck[2], J. Flores[1]; [1]FALP / PositronMed, Santiago, CHILE, [2]PositronPharma, Santiago, CHILE.

Patients with progressive metastatic castration-resistant prostate cancer (mCRPC) have limited therapeutic options and most of them are referred to palliative care. Several reports have confirmed that ^{177}Lu labeled prostate specific membrane antigen (PSMA) ligand is a safe and effective therapeutic option in progressive mCRPC. **Aim:** To present the initial experience in a Chilean oncology center using the theranostics concept with ^{68}Ga-PSMA-11 PET/CT and ^{177}Lu-PSMA-617 in patients with progressive mCRPC. **Subjects & Methods:** Thirteen consecutive patients with mCRPC, mean age 70±7.9 y.o. (range: 51-82), received a total of 43 doses of ^{177}Lu-PSMA-617 between June 2016 and April 2017 (eight patients: 4 doses, two patients: 3 doses, two patients: 2 doses and one patient: 1 dose). The mean administered activity per dose was 5.7±0.4 GBq (range: 4.7-6.3). All patients have a complete clinical and laboratory work-up including serum prostate specific antigen (PSA) levels before and after four weeks of every administered dose. A pre-therapy ^{68}Ga-PSMA-11 PET/CT (mCT 20, Siemens-Healthineers) was performed in all and a whole-body planar scan and SPECT/CT were acquired after each treatment application. **Results:** The ^{68}Ga-PSMA-11 PET/CT demonstrated bone metastatic involvement in all cases, additional lymphadenopathies in 62% and visceral metastases in 23%. Planar scan and SPECT/CT images after the initial treatment were in agreement with recent pre-treatment PET/CT findings. No acute adverse effects were observed after therapy. Until now no xerostomy cases has been detected. In one patient hematological toxicity grade 3 with pancytopenia was observed 4 weeks after the first dose. The initial mean PSA level was 672±1099 ng/dL (range: 3.4-4105). PSA level decreased in 7/10 patients with at least 3 doses and in 5/10 the decreased was more than 50% (71.5%, 95.1%, 97.6%, 99.7% and 99.8%, respectively). The two most significant

responses were: one patient with initial PSA level 18.3 ng/dL that decreased to 0.05 ng/dL and in a second patient the basal PSA level of 921.1 ng/dL diminished to 2.2 ng/dL, both after 4 doses of ^{177}Lu-PSMA-617. **Conclusion:** The theranostics approach with ^{68}Ga-PSMA-11 PET/CT and ^{177}Lu-PSMA-617 treatment in patients with progressive mCRPC is a safe and promising personalized therapy in a group of patients with currently limited therapeutic options. Our initial experience in Chile is in agreement with recent published data elsewhere and allows us to introduce this theranostics concept as a routine procedure in mCRPC patients.

M2M: Optical/Multimodality Imaging

OP-223

Diagnostic Tumor Imaging Using Renally Excretable Nanoparticles: Focus on Active and Passive Targeting

K. Pant[1], K. Zarschler[1], C. Neuber[1], J. Pufe[1], J. Steinbach[1,2], R. Haag[3], J. Pietzsch[1,2], H. Stephan[1]; [1]Helmholtz-Zentrum Dresden-Rossendorf, Institute of Radiopharmaceutical Cancer Research, Dresden, GERMANY, [2]Technische Universität Dresden, Department of Chemistry and Food Chemistry, Dresden, GERMANY, [3]Freie Universität Berlin, Department of Chemistry and Biochemistry, Berlin, GERMANY.

Introduction: Depending on their size, shape and surface functionalities, nanoparticles can passively extravasate and accumulate in the tumor tissue through the enhanced permeability and retention (EPR) effect. Being an accumulative process, this effect favors nanoparticles with long blood retention time. Renally excretable, ultrasmall nanoparticles with short blood half-lives are therefore less prone to passive tumor targeting as they rapidly diffuse back to the vasculature and re-enter the systemic circulation, which results in only transient intratumoral presence without substantial retention. To prevent their rapid efflux from malignant tissues by increasing the interactions between nanoparticles and tumor cells as well as by improving cellular nanoparticle uptake, the strategy of active or ligand-mediated targeting is pursued. Here, we describe the development of renally excretable dendritic polyglycerols (dPGs) functionalized with different targeting units to differentiate between active and passive tumor targeting. **Methods:** Fluorescent dye labels for optical imaging and small camelid single-domain antibodies (sdAbs) as targeting units - both equipped with maleimide functionalities - were simultaneously attached in a one-pot reaction to thiol groups of the dPGs. As the presented work focusses on the epidermal growth factor receptor (EGFR) acting as a model receptor, an EGFR-specific sdAb was attached to the dPGs to obtain an active targeting probe. In parallel, a probe with similar surface characteristics but a nonspecific sdAb (passive targeting) was synthesized. Both conjugates were purified using affinity chromatography, which selectively separates the sdAb-conjugated dPGs. **Results:** In vitro binding studies on different human epithelial cancer cell lines using dye-labeled sdAb-conjugated

dPGs showed a high specificity, co-localization and a receptor-mediated cellular uptake of the EGFR-specific probes. Optical imaging studies using murine xenografts revealed a substantial accumulation of the EGFR-specific probes in comparison to its nonspecific counterparts and a minimum off-target accumulation of both conjugates. **Discussion and Conclusion:** The direct comparison of specific and nonspecific probes with similar surface characteristics allows the straight-forward preclinical discrimination between active and potential passive tumor targeting of renally excretable nanoparticles in small animal models. Furthermore, it provides important information on the extent to which ligand-mediated targeting contributes to total nanoparticle accumulation in malignant and normal tissues.

OP-224

Multicolor fluorescence click-chemistry as a means to select membrane targets for pre-targeting by function of their internalization

S. van der Wal, C. M. de Korne, L. G. L. Sand, P. C. W. Hogendoorn, K. Szuhai, F. W. B. van Leeuwen, **T. Buckle**; LUMC, Leiden, NETHERLANDS.

Introduction: The internalization kinetics of membrane receptors plays an important role in theranostic approaches, especially in those that make use of pre-targeting. To enable accurate assessment of the validity of a membrane receptor in pre-targeting based approaches (e.g. availability on the cell membrane), a novel "click" chemistry-based fluorescence quenching concept was developed. Herein the fluorescent emission of the extracellular tracer fraction can be "switched-off" or "de-activated". The efficacy of this approach was evaluated for the chemokine receptor 4 (CXCR4), a clinically relevant theranostic receptor-target that is over-expressed in e.g. multiple myeloma, breast cancer and Ewing sarcoma. Findings were compared to a targeted tracer that becomes activated following cellular internalization. **Methods:** Ac-TZ14011, a CXCR4 specific peptide, was converted into two types of receptor-targeted tracers: 1) a de-activatable tracer; a Cy5 dye that contained a chemo-selective azide handle suitable for pre-targeting applications (**N₃-Cy5-AcTZ14011**) that can react with a Cy7 quencher dye (**Cy7-DBCO**) to form the optically silent **Cy7-["click"]-Cy5-AcTZ14011** and 2) an activatable tracer; a FRET-dye construct (**Cy5-S-S-Cy3-AcTZ14011**) that is optically silent for Cy3 and becomes Cy3 fluorescent (**HS-Cy3-AcTZ14011**) upon cleavage of the disulfide bond. The photophysical properties and activation kinetics of both tracers were evaluated *in situ*. *In vitro* assessment of the binding affinity (flow cytometry; saturation binding experiments (K_D)) and internalization kinetics (fluorescence confocal microscopy; quantitative evaluation over time) was performed in CXCR4 overexpressing MDAMB 231 X4 cells. **Results:** Assessment of the binding affinity of both tracers revealed that the smaller **N₃-Cy5-COOH** had a higher binding affinity than **Cy5-S-S-Cy3-COOH** (K_D: 222.4 ± 25.2 nM vs. K_D > 500 nM, respectively). *In situ*, addition of **Cy7-DBCO** to **N₃-Cy5-AcTZ14011** resulted in >90% FRET-based reduction of the signal intensity of Cy5 fluorescence within the first 2-5 minutes. In cells, pre-targeting with **N₃-Cy5-AcTZ14011** led to membranous staining and subsequent internalization of the receptor-tracer complex. Following addition of **Cy7-DBCO,** an 80% decrease of membranous fluorescence was seen, while fluorescence of the internalized tracer-fraction was preserved and remained stable over time (0-30 minutes). The FRET efficiency of the disulfide-bridge-containing activatable tracer was 55% and a limited 45% increase in fluorescence was seen upon reduction in solution, while in cells no increase in Cy3-related fluorescence was seen. **Conclusions:** De-activatable fluorescence tracers were shown to provide a clear alternative for activatable tracers. Moreover, the click chemistry-based pre-targeting approach promises to provide an efficient read-out that for the screening of membrane receptors and their applicability in receptor-targeted theranostics.

OP-225

Multicolor fluorescence imaging as a means to reduce the toxicity during nodal dissections in prostate cancer

P. Meershoek[1,2], G. H. KleinJan[1,2], M. N. van Oosterom[1], E. M. Wit[2], N. Grivas[2], A. Mottrie[3], F. W. B. van Leeuwen[1], H. G. van der Poel[2]; [1]Leiden University Medical Center, Leiden, NETHERLANDS, [2]Netherlands Cancer Institute (NKI-AvL), Amsterdam, NETHERLANDS, [3]OLV Vattikuti Robotic Surgery Institute, Melle, BELGIUM.

Introduction: Lymphatic metastases are frequently encountered in prostate cancer. Therefore the EAU guidelines indicate an extended pelvic lymph node dissection (ePLND). Disturbance of the lymphatic flow is common after an ePLND and can result in side effects such as lymphocele and lymphedema. We reasoned accurate distinction between relevant prostate draining sentinel lymph nodes (SNs) and crucial leg draining lymph nodes (LNs) could reduce the degree of disturbance inflicted to the lymphatic flow. This study aims to intraoperatively differentiate the lymphatic drainage of the prostate from that of the legs using two complementary fluorescent signatures. **Materials and Methods:** Five pigs were included in this study. All animals were adminstered 5mL fluorescein solution (subcutaneous and intramuscular) in the hind leg(s). After allowing drainage to occur for two hours 2ml indocyanine green (ICG-) nanocolloid was intraoperatively injected into the prostate via percutaneous robot-guided needle placement (two - four deposits). Hereafter the different lymphatic drainage patterns were mapped with Firefly laparoscopic fluorescence cameras of the daVinci Si and Xi systems. **Results:** Fluorescein was detected in 29 LNs (average of 5.8 LNs/animal). Two of the five animals got a single sided injection in the right hind leg, which only resulted in the visualization of fluorescein-stained lymph nodes on that side of the anatomy. ICG-nanocolloid visualized 15 prostate related SNs (average of 3 SNs/animal) of which 8 were situated in the left pelvic area and 7 in the right. There was no overlap in the lymphatic drainage pattern of the two different dyes. While ICG-nanocolloid could only be detected using dedicated near-infrared imaging, fluorescein was also visible to the eye in the white light imaging mode. Fully integrated multispectral visualization of the complementary dyes fluorescein and ICG-nanocolloid was most succesfull with the daVinci Si set-up. **Discussion and Conclusion:** We demonstrated the

possibility to distinguish two different lymphatic flow patterns using fully integrated multicolor fluorescence imaging. These preclinical findings motivate further clinical follow-up as this approach can help to further refine lymphatic dissections and with that help maintain the quality of life of the patients.

OP-226

Development of a tumor microenvironment(FAP alpha) targeted near infrared dye for fluorescence guided surgery of cancers

J. Roy[1,2], P. S. Low[2]; [1]National Cancer Institute, Bethesda, MD, UNITED STATES OF AMERICA, [2]Purdue University, West Lafayette, IN, UNITED STATES OF AMERICA.

Aim: Fibroblast activation protein alpha (FAPα), a type II integral membrane proteinase, has emerged as a marker for cancer-associated fibroblasts (CAFs), which constitute one of the major cell types present in the solid tumor microenvironment. Because the FAPα expression is otherwise restricted to myofibroblasts and sites of wound healing/chronic inflammation, its expression in 90% of epithelial tumors has led to the development of drugs aimed at suppressing the growth of epithelial cancers. To date, however, no FAPα-targeted imaging agent has been developed for imaging of solid tumors using non-peptidic, small molecule ligand. Herein we report the in vitro and in vivo (mice xenografts) imaging with a small molecule FAPα-specific ligand(FL) linked to a near-infrared (NIR) dye for use in illuminating cancer nodules during fluorescence-guided surgery. **Methods:** Rhodamine (FL-L1-Rho) and NIR (FL-L1-NIR) conjugates were synthesized using FL linked to the dyes via a non-releasable small spacer. The expression of FAPα in MDA-MB231(M), FaDU(F), KB(K), and HT29(H) cells was determined by using FL-L1-Rho whereas the binding affinity(Kd) of FL-L1-NIR was determined by using FAPα-transfected HEK-293 cells(HEK-FAPα). Whole body and biodistribution studies were performed 2 h post-injection of M, F, K, or H xenografts with FL-L1-NIR (in the presence or absence of FL). The images were taken by using IVIS Lumina II imager. **Results:** In vitro, the cancer cells demonstrated no uptake of FL-L1-Rho indicating the absence of FAPα. The FL-L1-NIR exhibited a high binding affinity (K_d=3.7 nM) in HEK-FAPα cells. When tested in vivo the FL-L1-NIR showed FAPα mediated uptake in the tumor xenografts in which the cancer cells itself were negative for FAPα. The uptake of FL-L1-NIR was blocked in the presence of an excess of FL. Furthermore, the biodistribution study suggested that other than tumors there was minimal or no uptake in other tissues/organs except kidneys which was due to excretion of the conjugate via renal route. **Conclusion:** Through our, in vitro and in vivo studies we could demonstrate that the cancer cells itself did not express FAPα instead it is expressed by the cells of tumor microenvironment. Multiple xenografts were readily imaged following tail vein injection of the FAPα-targeted NIR dye conjugate. Because of tumor-specific uptake of FL-L1-NIR and little or no uptake in any healthy tissues/organs (except kidney during normal excretion of the dye), we conclude that FAPα constitutes an excellent tumor-microenvironment specific antigen and FAPα-targeted

imaging conjugates should prove useful in imaging most human solid tumors.

OP-227

SPECT-based navigation of fluorescence cameras during soft-tissue surgery - is it possible to use a single navigation setup for various open and laparoscopic radioguided surgery applications?

M. N. van Oosterom[1], P. Meershoek[1], G. H. KleinJan[1], K. Hendricksen[2], N. Navab[3], C. J. H. van de Velde[1], H. G. van der Poel[2], F. W. B. van Leeuwen[1]; [1]Leiden University Medical Center, Leiden, NETHERLANDS, [2]The Netherlands Cancer Institute - Antoni van Leeuwenhoek Hospital, Amsterdam, NETHERLANDS, [3]Technical University Munich, Munich, GERMANY.

Introduction: Providing real-time intraoperative visualization, fluorescence-guided surgery is increasingly gaining popularity. However, due to tissue-induced signal attenuation and scatter, the technology is mainly suitable for superficial applications (<1 cm deep). This also limits its use for surgical planning, where nuclear imaging remains the gold standard for non-invasive molecular (total-body) imaging. To compensate for the in-depth shortcomings of fluorescence-guidance, intraoperative positioning of the fluorescence camera can be achieved using the available 3D nuclear imaging data in a dedicated navigation setup. At the same time, underlying navigation inaccuracies, typically arising in soft-tissue anatomies, can be corrected for using the real-time fluorescence feedback. **Materials and Methods:** In this study, a fluorescence camera, with scopes available for both open and laparoscopic procedures, was integrated with a navigation platform, creating one setup for various surgical indications. After camera-system calibrations, navigation targets were shown as augmented reality (AR) overlays in the fluorescence-camera video feed. Using the hybrid tracer indocyanine green (ICG)-^{99m}Tc-nanocolloid, which harbors both a near-infrared fluorescent (ICG) and radioactive (^{99m}Tc) moiety, these navigation targets were generated based on either preoperative single-photon emission computed tomography/computed tomography (SPECT/CT) or intraoperative freehand SPECT (fhSPECT) imaging. The accuracy of this proposed setup was thoroughly evaluated in a phantom study. This was followed by a first-in-human (n=4) translation into radioguided-sentinel lymph node (SN) procedures for penile (open surgery) and prostate (laparoscopic surgery) cancer. **Results:** Overall, the phantom navigation studies revealed a mean tool-target distance accuracy of 2.1 (SPECT/CT) and 3.2 mm (fhSPECT) and a mean AR registration accuracy of 1.1 mm (SPECT/CT) and 2.2 mm (fhSPECT). Using intraoperative fhSPECT imaging, in-human navigation efforts during both open and laparoscopic surgery were directed towards either the primary tumor site or the SNs. In all patients, fhSPECT-based navigation of the fluorescence camera was accurate enough to localize the fluorescence signals of the targeted tissues *in vivo*; thus localizing the tissue to excise. **Conclusion:** Both phantom and in-human studies performed suggest the single navigation setup presented is applicable in both open and laparoscopic radioguided surgery.

By successfully combining the complementary imaging information of both nuclear and fluorescence imaging, the setup allowed for *in vivo* localization of the targeted tissue. Further evaluation, including larger patient groups and a greater variety of malignancies, is recommended to strengthen these results.

OP-228

Molecular imaging of malaria through fluorescent labelling of Plasmodium species within the mosquito host

B. M. F. Winkel, M. N. Oosterom, A. Bunschoten, M. M. Welling, M. C. C. Langenberg, B. Franke-Fayard, C. De Korne, S. C. Chevalley, M. Yazdanbakhsh, F. W. B. van Leeuwen, M. Roestenberg; *LUMC, Leiden, NETHERLANDS.*

Purpose/Introduction: The pre-erythrocytic stage of human malaria is a promising target for malaria vaccine development as parasite numbers are still relatively low and disease symptoms are absent. While attenuated malaria parasites (sporozoites) can be used to induce protective immunity in man, their mode of action is still unclear. In particular, analysis of the elusive human malaria skin phase is needed to improve attenuated sporozoite vaccines. Here sporozoite cell tracking can provide the solution. To realize such imaging studies, we developed a tracer-based method that targets mitochondria (both in vitro as well as within the mosquito host) that allows quantitative tracking of sporozoites in human skin. **Methods:** Sporozoites present in salivary glands of Anopheles stephensi mosquitoes infected with rodent malaria (Plasmodium yoelii or berghei) or human malaria (Plasmodium falciparum) were labelled with TCy5M2. The labelling efficacy was assessed using fluorescence confocal microscopy, conventional fluorescence microscopy and flow cytometry. For evaluation of the movements of sporozoites in the skin 10^6 in vitro TCy5M2 labelled Plasmodium yoelii or wild-type Plasmodium falciparum sporozoites were intradermally injected into human skin explants. Biopsy samples of the injection sites were imaged with fluorescence confocal microscopy for 30-60 minutes. Sporozoite motility in the skin was analysed using tailored MATLAB software. **Results:** In infected mosquito hosts (*in vivo*) and in isolated sporozoite specimens (*in vitro*) TCy5M2 was shown to rapidly accumulate in the mitochondria of sporozoites. Quantification of fluorescence showed a 100-fold increase of fluorescence compared to unstained controls. TCy5M2 labelling did not affect the viability and infectivity of sporozoites (*in vitro* or *in vivo*). Monitoring of migration of *in vitro* TCy5M2 labelled *Plasmodium falciparum sporozoites* in human skin allowed isolation of the dynamic behaviour of the sporozoites and evaluation of differences in directional movement (linear or circular), as well as measurement of velocity and displacement. **Conclusion:** In order to circumvent the need for genetic labels, we have developed a tracer-based molecular imaging method that allows imaging of different *Plasmodium* species at the single cell level. This initial proof-of-concept study shows that this technology can provide a first step towards unravelling the mystery of skin migration of malaria parasites in humans, making molecular imaging a crucial step on the path towards an effective vaccine against pathogens.

OP-229

[⁶⁸Ga]PSMA-I&F: a first successful step towards PSMA-targeted bimodal probes for radio- and fluorescence guided surgery of prostate cancer

M. Schottelius[1], A. Wurzer[1], K. Wissmiller[1], R. Beck[1], J. Notni[1], M. Koch[2], D. Gorpas[2], V. Ntziachristos[2], M. Schwaiger[3], T. Buckle[4], F. van Leeuwen[4], H. Wester[1]; [1]Pharmaceutical Radiochemistry, TUM, Garching, GERMANY, [2]IBMI, Helmholtz Center Munich, Munich, GERMANY, [3]Dept. of Nuclear Medicine, TUM, Munich, GERMANY, [4]Radiology, Leiden University Medical Center, Leiden, NETHERLANDS.

Objectives: [⁶⁸Ga/¹⁷⁷Lu]PSMA-I&T and [⁹⁹ᵐTc]PSMA-I&S are currently successfully employed for clinical PET imaging, radionuclide therapy and radioguided surgery, respectively, of prostate cancer (PC/mCRPC). To be able to exploit the high intrinsic sensitivity and spatial resolution of fluorescence imaging, a first PSMA-I&T-based bimodal agent, PSMA-I&F (nuclear imaging/fluorescence imaging; DOTAGA-k(Sulfo-Cy5)-(i-y)-(i-y)-k-Sub-KuE) has been developed and evaluated. **Methods:** PSMA-affinities (IC_{50}) of PSMA-I&F and its natGa-/natLu-complexes in comparison to the reference compounds natGa/natLu-PSMA-I&T were determined using human LNCaP PC cells and [¹²⁵I]IBA-KuE as radioligand. PSMA-specific internalization (LNCaP cells, 37°C, 0-60 min) of [⁶⁸Ga/¹⁷⁷Lu]PSMA-I&F (2 nM) was investigated in a dual tracer radioligand assay using [¹²⁵I]IBA-KuE (0.2 nM) as internal standard and via fluorescence microscopy (ligand concentration: 25nM). Biodistribution and small-animal PET imaging studies (1h p.i., 0.2 nmol [⁶⁸Ga]PSMA-I&F/mouse) were performed in LNCaP xenograft bearing SHO mice. For one animal, fully automated serial cryosectioning and fluorescence imaging was also carried out (1h p.i., 2 nmol natGa-PSMA-I&F). **Results:** Compared to the parent compounds natGa/natLu-PSMA-I&T (IC_{50}=9.4±2.9 and 7.9±2.4 nM, respectively), PSMA-I&F and its natGa-/natLu-complexes showed very similar PSMA-affinities (10.3±0.7, 10.5±2.1 and 9.6±1.7 nM), which were also reflected in equally efficient tracer internalization for [⁶⁸Ga/¹⁷⁷Lu]PSMA-I&F (103±9 and 106±2% of [¹²⁵I]IBA-KuE after 1h, respectively) compared to [¹⁷⁷Lu]PSMA-I&T (114±8% of [¹²⁵I]IBA-KuE). Fluorescence microscopy revealed PSMA-specific internalization of membrane-bound natGa/natLu-PSMA-I&F into endosomal vesicles within 1h. In vivo, relatively pronounced plasma protein binding (93.7%) resulted in slightly delayed blood clearance of [⁶⁸Ga]PSMA-I&F (2.1±0.4 %iD/g in blood at 1h p.i.). Based on its hydrophilicity (logP= -3.2), however, background accumulation of [⁶⁸Ga]PSMA-I&F was very low (0.9±0.1 and 0.5±0.2%iD/g in liver and intestines, respectively). Dynamic PET imaging confirmed specific (as demonstrated by coinjection of 1μmol PMPA) and consistently increasing uptake into the PSMA-expressing tumor (4.5±1.8%iD/g), kidneys and spleen (106±23 and 13±7%iD/g, respectively) within 1.5h, accompanied by progressive background clearance. Fluorescence imaging of the whole-body cryoslices revealed pronounced inhomogeneity of PSMA-expression in the LNCaP xenograft, homogenous probe uptake in the salivary glands and the renal cortex and in PSMA-expressing ganglia. **Conclusion:** With its high PSMA-specific uptake and its suitable pharmacokinetic profile, [⁶⁸Ga]PSMA-I&F serves as an excellent proof-of-concept

compound for the general feasibility of PSMA-I&T-based bimodal imaging. Based on these results, corresponding hydrophilic [99mTc]-labeled analogs with improved suitability for clinical application in radio- and fluorescence guided surgery of oligometastasized PC have been synthesized and are currently under evaluation.

OP-230

s-Tetrazine: a "clickable" platform for the site-specific dual-labeling of proteins

C. Canovas[1], M. Moreau[1], C. Bernhard[1], M. Cordonnier[2], J. Gobbo[3], A. Oudot[3], F. Denat[1], **V. Goncalves**[1]; [1]Université de Bourgogne, Dijon, FRANCE, [2]INSERM, UMR 866, Laboratoire d'Excellence LipSTIC, Dijon, FRANCE, [3]Centre Georges-François Leclerc, Dijon, FRANCE.

Introduction: Bioconjugates have become essential tools in biomedicine. Among them, doubly-modified proteins constitute an emerging class, which open new fields of application such as bimodal medical imaging and theranostics. Unfortunately, the multiple modification of a protein is still a fastidious and challenging task. In particular, it requires a careful control of the conjugation site(s), as the number and the localization of imaging/therapeutic payloads attached to an antibody can have a dramatic effect on its biodistribution. Here we propose an original approach, based on the use of dichloro-*s*-tetrazine as a platform, for the site-specific dual-labeling of proteins. Dichloro-*s*-tetrazine acts as a trifunctional scaffold to assist the assembly of two agents (imaging, cytotoxic or solubilizing) with a targeting biomolecule. Interestingly, thanks to its ability to undergo an iEDDA reaction, tetrazine makes possible the site-specific dual-labeling of proteins on a single non-canonical amino acid. To validate this strategy, a doubly-modified trastuzumab, suitable for SPECT/optical bimodal imaging, was prepared through site-specific labeling and evaluated in vivo. **Materials and Methods:** Dichloro-*s*-tetrazine was functionalized, by two successive S_NAr reactions, with a macrocyclic chelator (DOTA-GA or NODAGA) and a fluorophore (Rhodamine B, BODIPY or Cyanine 5.0). The bimodal probe substituted with both a DOTAGA and a disulfonated cyanine 5.0, was selected to achieve the study. Vectorization of the bimodal probe was performed via iEDDA reaction between the tetrazine derivative and an anti-HER2 antibody (trastuzumab) previously modified with a bicyclo-1,6-nonyne (BCN). The affinity of the bioconjugate was determined in vitro by BLI. The bioconjugate, radiolabeled with [111In] was injected in BALB/c nude mice xenografted with BT-474 cancer cells. SPECT-CT, optical images and biodistribution data were acquired 24h after the injection. **Results:** In order to demonstrate the simplicity and the versatility of our strategy, a library of "clickable" disubstituted tetrazines, suitable for bimodal imaging applications, was synthesized. Trastuzumab-BCN was successfully doubly-modified via a bioorthogonal reaction (protein recovery: 46%). In vitro studies confirmed the high affinity of trastuzumab for HER2. The radio-labeling by [111In] was achieved at 37°C in 3h. Evaluation in xenografted mice confirmed the favorable biodistribution properties of the dual-labeled trastuzumab and thus validated the viability of our technology. **Conclusion:**

This highly modular strategy enables the production of doubly modified proteins with an efficient control of the bioconjugation step by site-specific labeling. This technology should facilitate the production of such biomolecules and enable the explosion of this next generation of bioconjugates.

OP-236
Textural features assessed by dual time point 18 FDG PET/CT in locally advanced breast cancer: Relation with SUV-based variables and tumor biology

A. García Vicente[1], *G. Jimenez Londoño*[1], *D. Molina*[2], *J. Perez-Beteta*[2], *M. Amo-Salas*[3], *A. Martinez Gonzalez*[2], *M. Tello Galan*[1], *V. Perez-Garcia*[2], *A. Soriano Castrejon*[1]; [1]*General Hospital of Ciudad Real, Ciudad Real, SPAIN*, [2]*IMACI. Universidad de Castilla La Mancha, Ciudad Real, SPAIN*, [3]*Departamento de Matemáticas. Unicersidad de Castilla La Mancha, Ciudad Real, SPAIN.*

Purpose: To study the influence of dual time point 18F-FDG PET/CT in textural features and their relation with SUV-based variables and biological breast tumor characteristics. **Subjects & Methods:** 56 patients with locally advanced breast cancer (LABC) were prospectively included. All of them underwent a standard 18F-FDG PET/CT (PET-1) and a delayed acquisition

(PET-2). After segmentation, SUV variables (SUVmax, SUVmean and SUVpeak) and volume-based parameters as metabolic tumor volume (MTV) and total lesion glycolysis (TLG) were obtained. Eighteen three-dimensional (3D) textural measures were computed including: run-length matrices (RLM), co-occurrence matrices (CM) and energies features. Immunohistochemical characteristics of the tumors were collected to establish risk categories attending to molecular phenotypes: high risk [basal like or HER2 (+) pure], intermediate risk [luminal B-HER2 (-) or luminal B-HER2 (+)] and low risk [Luminal A]. Differences of metabolical variables obtained in dual time point PET/CT and their relations with biological risk categories were assessed. A significance level of p-value <0.05 and correlation coefficient values over 0.75 were taken as indicators of strong correlation. **Results:** Significant differences were found between the SUV based parameters and MTV obtained in the dual time point PET/CT, with higher values of SUV based variables and lower MTV in the PET-2 with respect to those in the PET-1. As to the textural parameters obtained in dual time point acquisition, significant differences were found for the SER (Short Run Emphasis), LGRE (Low Gray-level Run Emphasis), SRHGE (Short Run High Gray-level Emphasis), RPC (Run Percentage), LRE (Long Run Emphasis), GLNU (Gray-Level Non-Uniformity), HOM (Homogeneity) and DIS (Dissimilarity). Total energy (TE), LRE and LRHGE (Long Run High Gray-Level Emphasis) showed strong correlations with volume-based variables and phenotype risk categories. **Conclusion:** Significant differences of textural features were found in dual time point 18F-FDG PET/CT. The dynamic behavior of metabolic characteristics leads to higher heterogeneity in delayed PET acquisition compared with the standard PET. Textural features were also related to volume and biological tumor characteristics. Specifically, larger heterogeneity measures were obtained for bigger and more aggressive tumors.

First Interim Results of the Radium-223 REASSURE Observational Study: Analysis of Patient Characteristics and Safety by Prior Use of Chemotherapy

S. Dizdarevic[1], P. Meidahl Petersen[2], M. Essler[3], A. Versari[4], J. Bourre[5], C. La Fougère[6], R. Valdagni[7], G. Paganelli[8], S. Ezziddin[9], J. Kalinovský[10], Y. De Sanctis[11], Y. Du[12]; [1]Royal Sussex County Hospital, Brighton and Sussex University Hospitals NHS Trust, Brighton, UNITED KINGDOM, [2]Rigshospitalet, Copenhagen, DENMARK, [3]Universitätsklinikum Bonn, Bonn, GERMANY, [4]Azienda Ospedaliera Arcispedale Santa Maria Nuova – IRCCS, Reggio Emilia, ITALY, [5]Centre Hospitalier Métropole Savoie, Chambery, FRANCE, [6]Universitätsklinikum Tübingen, Tübingen, GERMANY, [7]Università degli Studi di Milano and Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, ITALY, [8]Istituto Scientifico Romagnolo per lo Studio e la Cura dei Tumori, Meldola, ITALY, [9]Universitätsklinikum des Saarlandes, Hamberg, GERMANY, [10]Bayer, Bratislava, SLOVAKIA, [11]Bayer, Whippany, NJ, UNITED STATES OF AMERICA, [12]Royal Marsden Hospital, London, UNITED KINGDOM.

Aim: Radium-223, a targeted alpha therapy, was shown to extend survival with a favourable safety profile during 3 years' follow-up in patients with metastatic castration-resistant prostate cancer (mCRPC) in the phase 3 ALSYMPCA trial. The REASSURE study was designed with 7 years' follow-up to determine the long-term safety profile of radium-223 and to assess potential treatment-induced secondary malignancies. Here we report the safety data and patients' characteristics from the first planned interim analysis. **Methods:** REASSURE is a global, prospective, single-arm, observational study that enrolled patients with mCRPC with bone metastases for whom radium-223 therapy was planned. It enrolled 1106 patients in North America and Europe from September 2014 to September 2016. The interim analysis by prior use of chemotherapy included data from 583 patients who had completed treatment (median duration of observation 7 months). **Results:** Out of 583 patients, 196 (34%; Group 1) had previously received docetaxel and/or cabazitaxel and 387 (Group 2) had not. At baseline, patients in Group 1 vs. Group 2 were less often ECOG 0-1 (70% vs. 81%), had more metastatic lesions (<6: 23% vs. 34% of patients; 6-20: 52% vs. 57%; >20 [not superscan]: 26% vs. 16%; superscan: 9% vs. 5%), and had higher median levels of prognostic markers (alkaline phosphatase: 162 vs. 115 U/L; prostate-specific antigen: 136 vs. 41 ng/mL). Groups 1 and 2 had similar baseline median levels of haemoglobin (11.8 and 12.3 g/dL, respectively) and platelets (236 and 233 GIGA/L, respectively). Regardless of prior chemotherapy, the majority of patients received 5 or 6 radium-223 doses (Group 1: 54% [median 5 doses]; Group 2: 68% [median 6]). In Groups 1 and 2, respectively, drug-related serious adverse events (AEs; most frequently haematological) occurred in 7.1% and 3.1% of patients and led to permanent discontinuation of radium-223 in 2.0% and 1.3%, while treatment-emergent drug-related AEs (most frequently gastrointestinal or haematological) occurred in 40.3% and 35.1% of patients and led to permanent discontinuation of radium-223 in 9.2% and 4.4%. Overall, bone marrow suppression-relevant treatments were reported for 71/583 (12.2%) patients and blood transfusions for 69/583 (11.8%) patients. Erythropoetins and colony-stimulating factors were each received by 1 (0.2%) patient. **Conclusions:** Radium-223 showed a good short-term safety profile in both groups when used in the routine clinical practice setting. Patients not previously treated with chemotherapy had less advanced disease at baseline than prior chemotherapy recipients and the majority of them completed 5-6 doses of radium-223.

OP-238

Repeatability of tumour hypoxia imaging using [¹⁸F]EF5 PET/CT in head and neck cancer

A. Silvoniemi[1,2], S. Suilamo[1,2], T. Laitinen[1], S. Forsback[1], E. Löyttyniemi[3], V. Saunavaara[1,2], O. Solin[1], T. J. Grönroos[1,2], H. Minn[1,2]; [1]Turku PET Centre, University of Turku, Turku, FINLAND, [2]Turku University Hospital, Turku, FINLAND, [3]University of Turku, Turku, FINLAND.

Introduction: Hypoxia contributes to radiotherapy (RT) resistance and more aggressive behavior of several types of cancer. [¹⁸F]EF5 is a PET tracer showing preferential uptake in hypoxic tissues. Repeatability of hypoxia imaging is of key importance

for biologically guided RT aiming to adapt the dose in poorly oxygenated tissues. This is the first study designed to evaluate the repeatability of intratumour uptake of [18F]EF5 in PET/CT scans. **Subjects & Methods:** Eleven patients with untreated head and neck cancer referred to chemoRT were enrolled. Each patient received three pre-treatment PET/CT scans: two with [18F]EF5 a median of 7 days (range 5-7) apart and one with [18F]FDG following the standard institutional protocol used in RT planning. One patient was excluded from the analyses due to extremely low tracer uptake in the primary tumour in all PET images post diagnostic tonsillectomy. The mean (SD) injected activity of [18F]EF5 was 303 (23) MBq and the 6-min acquisitions were performed a mean (SD) of 178 (9) minutes post injection. [18F]FDG images were rigidly registered with [18F]EF5 images using anatomical information from CT images. Metabolically active primary tumour volumes were defined in [18F]FDG images and transferred to [18F]EF5 images. These volumes were used as volumes of interest in the tumour and voxel level analyses. Tumour-to-muscle uptake ratio (TMR) of 1.5 was used as a threshold representing hypoxic tissue. **Results:** In the 10 paired [18F]EF5 image sets, the average tumour SUV_{mean} and SUV_{max} were 1.52 (0.18) and 2.11 (0.33), respectively. The normally distributed tumour level parameters (SUV_{mean}, SUV_{max} and TMR) showed a good correlation between the scans with the intraclass correlation coefficients of 0.81, 0.85 and 0.87, respectively. The corresponding coefficients of repeatability for these parameters were 15%, 17% and 10%, respectively. Hypoxic subvolumes of the tumours in the repeated scans had a high correlation using Spearman rank correlation test (r= 0.927). In the voxel-by-voxel uptake analysis between the repeated scans the mean of Pearson correlation coefficients (r) of individual patients was 0.65 (range 0.48 - 0.87). The mean (SD) difference of voxel-level uptake (SUV_{scan2}-SUV_{scan1}) in pooled data set was 0.06 (0.22). **Conclusion:** A high repeatability of tumour level parameters was observed in the paired [18F]EF5 PET/CT scans acquired before onset of chemoRT. The voxel-by-voxel analyses showed predominantly good or moderate correlation and agreement between the repeated scans. Our results thus encourage further evaluation of [18F]EF5 PET/CT as a tool for hypoxia targeted treatment interventions.

OP-239

Prostate-Specific Antigen Flare Induced by (223)Ra therapy in Patients with Metastatic Castration-Resistant Prostate Cancer

A. Castello[1,2], *H. A. Macapinlac*[2], *E. B. Santos*[2]; [1]*Nuclear Medicine Unit, Department of Experimental and Clinical Biomedical Sciences, Florence, ITALY,* [2]*Department of Nuclear Medicine, The University of Texas MD Anderson Cancer Center, Houston, TX, UNITED STATES OF AMERICA.*

Purpose: PSA flare is a well-known phenomenon in patients with prostate cancer treated with luteinizing hormone-releasing hormone (LHRH) and chemotherapy, but its impact on patients treated with radium-223 dichloride ($^{223}RaCl_2$) is still unclear. This alpha-emitter is the first calcium-mimetic radioisotope that has been shown to improve overall survival in metastatic castrate-resistant prostate cancer (mCRPC). We sought to evaluate the incidence and the significance of PSA flare on $^{223}RaCl_2$ and its relation on survival. **Materials and Methods**: We conducted a retrospective study of 169 patients with mCRPC who received $^{223}RaCl_2$ between August 2013 and February 2017. Baseline characteristics, disease history and PSA level before and during $^{223}RaCl_2$ therapy were collected. Overall survival (OS) and radiological/clinical progression free survival (PFS), estimated by the Kaplan-Meier method and compared using log-rank test, were evaluated to compare patient subgroups with a PSA flare, immediate decline, and without response. **Results**: An immediate PSA decline was observed in 50 patients (30%) and a PSA flare (defined as any rise after the first cycle followed by any decrease below the peak) in 40 patients (24%), whereas no responders were observed in 61 patients (36%). The 18 remaining patients (11%) had PSA flare followed by decrease below the baseline. This PSA flare subgroup was associated with a median PFS and OS of 26.2 and 23.4 months, respectively. These outcomes were not significantly different from those in patients with immediate PSA decrease from baseline, but were significantly better than in patients with persisted increase (7.4 months for PFS and 11.5 months for OS, both **p** < 0.001). Moreover, the PSA flare group was correlated with the number of $^{223}RaCl_2$ cycles and with improved (or at least stable bone metastases) status than no responder patients (**p** = 0.03). **Conclusion**: The duration of response in our patients with PSA flare after $^{223}RaCl_2$ suggests a change in the tumor environment compared to patients who develop disease progression. To our knowledge, this is the first study about PSA flare in $^{223}RaCl_2$ and its implications on mCRPC therapy. This report suggests that a flare does not necessarily indicate lack of response to $^{223}RaCl_2$ and may in fact be predictive of a positive overall response.

OP-240

The Role of Texture Features Derived from FDG-PET/CT to Characterize Lung Lesions and Predict Survival in Non-Small Cell Lung Cancer Patients Undergoing Surgery

M. Kirienko[1], *M. Sollini*[1], *L. Cozzi*[2], *L. Antunovic*[2], *E. Voulaz*[2], *G. Veronesi*[2], *N. Gennaro*[1], *R. Muglia*[1], *O. Santonocito*[1], *A. Chiti*[1]; [1]*Humanitas University, Milano, ITALY,* [2]*Humanitas Clinical and Research Center, Milano, ITALY.*

Purpose: to evaluate the ability of textural features obtained from FDG-PET/CT images to predict histotype classification (adenocarcinoma (Adk) vs squamous cell (Sqc) carcinoma) and overall survival (OS) in lung cancer patients undergoing surgery. **Methods:** we retrospectively included 185 patients (114 Adk and 71 Sqc) who performed staging FDG-PET/CT from January 2011 to February 2017. FDG-PET/CT images were segmented on AW workstation running PET-vCAR software settled with a 40% SUV_{max} trashold. LifeX software was used to extract textural features from FDG-PET/CT images. Separate analysis has been performed within the 2 datasets of patients that were scanned on the 2 PET/CT scanners present in the department: Scanner A (Discovery 690, General Electric) group (60 Adk + 40 Sqc) and

Scanner B (Biograph, Siemens) group (54 Adk + 31 Sqc). Median follow-up was 20.7 months (range 0.23-69.33). The correlations between textural features and histotype were tested. The correlations between textural features and OS were assessed within Scanner A and B group irrespectively from the histotype. Statistical analysis was performed by R package. **Results:** At univariate analysis, more than 20 features derived from shape and size, gray level co-occurrence (GLCM), gray-level run-length (GLRLM), neighborhood gray-level difference (NGLDM), gray-level zone-length matrixes (GLZLM) resulted to be significantly (p<0.05) correlated to histotype, within both Scanner A and B group. Parameters significant at multivariate analysis resulted in a very good area under the curve using ROC analysis. For more than 10 features derived from the histogram, GLCM, GLRLM, NGLDM and GLZLM it was possible to identify a threshold that was able to separate the population, both Scanner a and B group, in groups with significantly different OS. **Conclusions:** FDG-PET/CT texture analysis seems a promising tool to characterize lung lesions and stratify lung cancer patients suitable of surgery with different outcome. A validation analysis is ongoing to confirm these preliminary results.

OP-241

Transitioning New Technology into the Reading Room - A Secondary Reconstruction Approach for Evaluation of Next-generation Digital PET/CT

K. Binzel[1], J. Zhang[1], C. L. Wright[1], P. Maniawski[2], M. V. Knopp[1]; [1]The Ohio State University, Columbus, OH, UNITED STATES OF AMERICA, [2]Philips Healthcare, Cleveland, OH, UNITED STATES OF AMERICA.

Aim: When introducing a new imaging system or technology, the transition to clinical use requires some level of training regarding improvements and differences from previous technology. With the commercial release of next-generation digital PET/CT, we aimed to create a reconstruction protocol that could best approximate visual and quantitative results from a previous generation scanner, to aid in the transition from conventional to digital PET imaging. **Materials and Methods:** 25 patients had a standard of care scan on a current generation clinical system (Philips Gemini TF 64, TOF 550ps, cPET) 75 minutes post-injection of 480 MBq ^{18}F-FDG. Either immediately before or following the SOC acquisition, patients underwent a secondary scan on a pre-commercial release digital PET/CT system (Philips Vereos, TOF 325ps, dPET). Accounting for the time delay between scans, we then reconstructed the dPET raw data using various settings in order to best match both visual and quantitative characteristics from the cPET scan. Reconstruction settings included using a 144x144 matrix with 4 mm voxel lengths, use of a Gaussian filter, using a lower number of iterative subsets than default reconstruction, and finally reconstruction without Time of Flight information. Two experienced readers evaluated the images for visual comparison. Quantitative evaluation included measuring SUV_{max} of target tumor lesions and SUV_{mean} of background tissues. **Results:** Regarding image quality, we found that the use of the Gaussian filter with a lower number of subsets lead to images being overly smoothed, as compared

to cPET image quality. Readers ranked the non-TOF images with a higher number of subsets as closest in visual appearance to the cPET images. Quantitatively, we found that while the low subset, Gaussian filtered reconstructions produced SUVs most similar to cPET, the non-TOF image sets still reflected a general decrease in SUV, similar to the overall lower SUVs measured on cPET. **Conclusion:** Familiarization with the way improving technology impacts both visual and quantitative aspects of imaging is a critical step in introducing new technologies in a clinical environment. While adaptation of a phantom based assessment, EARL for example, can be performed, intra-individual comparisons of clinical data sets give a more realistic perspective. We found that non-time of flight reconstruction of digital PET data best approximates how a scan would have looked on our conventional PET system. For patients receiving follow-up imaging on a new system, this secondary reconstruction approach will help with consistent and robust evaluation of digital PET/CT images.

OP-242

Radiomics analysis predicts N- and M-stage of primary cervical cancer using multiple PET/MR-derived quantitative features

J. Grueneisen, F. Nensa, K. Herrmann, A. Bariye, M. Forsting, L. Umutlu; University Hospital Essen, Essen, GERMANY.

Purpose: Integrated PET/MRI enables simultaneous acquisition of certain morphological, functional and metabolic parameters, reflecting underlying tumorbiological features. Accordingly, the present study aimed to assess the prediction potential of multiparametric PET/MRI for the evaluation of cervical cancer patients using radiomics analysis. **Subjects & Methods :** A total of 30 consecutive patients with histopathologically proven primary cervical cancer were prospectively enrolled for a 18F-FDG PET/MR examination, prior to the initiation of any treatment. Besides morphological MR imaging (T1w- and T2w-images), the study protocol included the acquisition of several PET- and MR-derived metabolic (18F-FDG PET: standardized uptake values) and functional (DWI: apparent diffusion coefficients (ADCs); DCE-MRI: K^{trans}, Kep, Ve, and iAUC) parameters. For all tumors of the uterine cervix the gross tumor volume was manually segmented using the Fiji software. Subsequently, a voxel-wise binary image mask of each primary tumor was created and quantitative imaging features were extracted using the Radiomic Image Processing Toolbox. Statistical analysis and modeling was performed in the R software environment for statistical computing and graphics. A generalized boosted regression model based on stochastic gradient boosting was trained to predict N- and M-status using the caret package. **Results:** Forty-five different image features were calculated from native T1- and T2-weighted images, the ADC map, the parametric Ktrans map and PET images, respectively, totaling 225 features. The 20 highest ranking features, based on *P* values of univariate analyses were selected and trained on a subset of 18 observations and tested on the remaining 12 observations. For the classification of N-stage the model achieved strong predictive power in the testing

group. Receiver operating characteristic analysis revealed an area under the curve of 0.97. At 100% sensitivity the model provided 80% specificity and an accuracy of 91% (95% confidence interval [59% - 100%]). For the classification of M-stage the model achieved perfect predictive power in the testing group. ROC analysis revealed an AUC of 1.0. At 100% sensitivity the model provided 100% specificity, resulting in an accuracy of 100% (95% confidence interval [72% - 100%]). Finally, a total of 6 identical image features were found to be top predictors of both M- and N-stage. **Conclusion:** Using Radiomics analysis based on multiparametric PET/MR datasets, our results reveal strong correlations between PET and MRI-derived quantitative features and major prognostic factors of cervical cancers. Therefore, PET/MRI datasets provide a number of non-invasive biomarkers, potentially facilitating improved tumor evaluation and prediction of prognosis.

OP-243

Simultaneous whole-body ^{18}F-PSMA-1007-PET/MRI with integrated high-resolution multiparametrical imaging of the prostatic fossa for comprehensive oncological staging of patients with prostate cancer

M. T. Freitag[1], C. Kesch[2], J. Cardinale[1], P. Flechsig[2], R. Floca[1], M. Eiber[3], D. Bonekamp[1], J. P. Radtke[2], C. Kratochwil[2], K. Kopka[1], H. Schlemmer[1], U. Haberkorn[2,1], F. L. Giesel[2,1]; [1]German Cancer Research Center, Heidelberg, GERMANY, [2]University Hospital Heidelberg, Heidelberg, GERMANY, [3]Technical University Hospital Munich, Munich, GERMANY.

Introduction: To explore the clinical feasibility, reproducibility and presence of PET-artifacts using a whole-body ^{18}F-PSMA-1007-PET/MRI protocol combined with integrated multiparametric prostate imaging for imaging prostate cancer (PC) patients. **Methods:** After ^{18}F-PSMA-1007-PET/CT was performed (1h p.i.) as reference, eight patients with proven high-risk PC underwent a whole-body PET/MRI (3h p.i.) including a prostate MRI protocol according to PIRADS 2.0 guidelines using a prototype T1w CAIPIRINHA-accelerated attenuation correction for enhanced whole-body workflow. SUV$_{mean}$ quantification for reproducibility was performed using a thresholded (60%) 3D-isocontour volume of interest of SUV$_{max}$. PET-artifacts (Cohen's kappa) on a scale from 0 to 3, coregistration of prostate PET/MRI (>3mm shift between bladder outline in PET and MRI) and prostate MRI (PI-RADS 2.0) were assessed. **Results:** The examinations were well accepted by patients and comprised 1 hour. SUV$_{mean}$ values between PET/CT (1h p.i.) and PET/MRI (3h p.i.) were linear (PET/CT 9.0±5.0, PET/MRI 11.4±6.1, p<0.0003 pathological VOIs and PET/CT 19.6±7.5, PET/MRI 21.8±10.4, p<0.0001 physiological VOIs) demonstrating reproducibility. Mostly slight to moderate photopenic artifacts were noticed in PET/MRI in the abdomen, surrounding liver and kidneys (kappa 0.82 (CI 0.62-1.00)) with a mean of 1.13±0.99 (reader 1) and 1.38±0.74 (reader 2). Both readers agreed to 100% that the PET-component of the PET/MRI did not reveal any artifacts in head/neck and thorax. Both readers agreed to 100% that the PET-component of the PET/CT did not reveal any artifacts

in the four compartments defined. All acquisitions of PET and MRI of the prostatic fossa obtained simultaneously could be co-registered with optimal match of bladder volume between both modalities. All patients featured PI-RADS 5 findings indicative of PC. **Discussion and Conclusion:** The presented ^{18}F-PSMA-1007-PET/MRI protocol combines efficient whole-body assessment with high-resolution co-registered PET/MRI of the prostatic fossa, cinically feasible in 1 hour. Moderate photopenic artifacts were noticed surrounding the high-contrast areas liver and kidneys reflecting the biodistribution of the tracer. However, compared to the known artifacts that may occur in ^{68}Ga-PSMA-11-PET/MRI in the bladder region, no artifacts were noticed there using ^{18}F-PSMA-1007 which we considered beneficial for assessment of pathologies arising in the prostatic fossa. This promising protocol is proposed as a comprehensive staging for patients with prostate cancer exploiting the optimal tracer biodistribution of ^{18}F-PSMA-1007 (low bladder clearance) and the synergistic combination of T-(MRI) and N/M-staging (PET and MRI).

OP-244

Combined use of Ga-68 PSMA-HBED and multiparametric MRI imaging of patients with carcinoma of the prostate in the primary staging setting and in cases of biochemical recurrence after radical prostatectomy

Z. E. Ballok[1,2], M. Frydenberg[3], K. Marshmann[1], R. O'Sullivan[1], D. Reilly[1]; [1]BRI, Richmond, AUSTRALIA, [2]MMC, Melbourne, AUSTRALIA, [3]Australian Urology Association, Malvern, AUSTRALIA.

Background: Both multiparametric MRI and Ga-68 PSMA-HBED imaging is a rapidly growing investigation of choice for assessment of patients with carcinoma of the prostate. **Aims**: To assess the complimentary role of multipara metric MRI and Ga68 PSMA-HBED PET scanning of patients with carcinoma of the prostate **Results**: Of the 116 consecutive patients from a single urology clinic, who underwent both multiparametric MRI scan and a Ga68-PSMA scan, 57 patients were referred for primary staging and 59 patients were imaged with biochemical recurrence after prior radical prostatectomy. Age of the patients was between 42 and 90 years with a median of 69 years and between 53 years and 80 years with a median of 68 years in the primary staging and in the biochemical recurrence group, respectively. PSA levels were between 1.6 and 2300 ug/L with a median of 6.8 ug/L and between 0.06 and 28 ug/L with a median value of 0.35 ug/L in the primary staging group and in the biochemical recurrence group, respectively. In the primary staging setting Ga68PSMA HBED PET scan accurately located more extensive, multifocal or bilateral disease as compared to multiparametric MRI scan in 11 cases, showed disease only on the contralateral site as compared to mpMRI scan in 1 patient, accurately predicted pelvic nodal metastasis in 5 more patients than mpMRI scan and down staged 2 patients with suspected boney metastatic disease on mpMRI scan. In the biochemical recurrence group multiparametric MRI detected 11 more local recurrence within the prostate bed region while Ga-68 PSMA-HBED imaging detected 3 distant metastases,

was convincingly positive within regions of small pelvic nodes within the pelvis in 9 cases with equivocal or negative findings on mpMRI while imaging results were concordant in 36 patients. Biopsy of two of the prostate bed region lesions found on mpMRI showed BPH only. **Conclusion**: Ga-68 PSMA-HBED imaging is currently the most accurate examination to detect the site(s) of metastasis/recurrence of previously treated carcinoma of the prostate with biochemical recurrence; however mpMRI is more accurate to demonstrate small local residual/recurrent prostate bed region lesions when this is the only site of recurrence. Our study also suggests that Ga-68 PSMA-HBED and mpMRI scans may also play complimentary role in the primary staging setting.

OP-245

Texture analysis is more predictive than SUV in 18F-Choline PET of the aggressiveness of prostate cancer

F. Hives[1,2], A. Fagart[2], K. Bouharati-Moussa[1], M. Fares[3], L. Drelon[4], P. Danjou[5], O. Decavel[6], B. Makki[1], S. Adib[1]; [1]Service de médecine nucléaire, centre hospitalier de Béthune, Béthune, FRANCE, [2]Service de médecine nucléaire, Université Lille 2, Lille, FRANCE, [3]Service de radiothérapie, Centre Pierre Curie, Béthune, FRANCE, [4]Service d'urologie, clinique des deux caps, Coquelles, FRANCE, [5]Service d'urologie, centre hospitalier de Lens, Lens, FRANCE, [6]Service d'urologie, clinique Anne d'Artois, Béthune, FRANCE.

Aim: Nowadays, prostate cancer is the most prevalent cancer in men. The ^{18}F-Choline, a membrane proliferation marker, is mainly used for the detection of recurrent prostate cancer. Its use in the diagnosis and the initial staging is still controversial. A potential application may be to increase the detection rate of clinically suspected prostate cancer with negative prostate biopsies. The use of texture analysis in nuclear medicine shown promising results to predict tumor aggressiveness, response to therapy or survival prognostic in neoplastic diseases. Our aim was to assess the tumor aggressiveness of prostate cancer according to the Gleason scoring using the texture analysis of ^{18}F-Choline in positron emission tomography (PET). **Materials and Methods:** Our study is a retrospective analysis of 55 patients with prostate cancer who underwent ^{18}F-Choline PET in initial staging, strictly before treatment. Gleason scores were analyzed from the initial needle biopsy. They were allocated as: 3+3 (n=11, group 1), 3+4 (n=23, group 2) and >3+4 (n=21, group 3). We performed an adaptive threshold of the whole prostate to extract intensity (SUV_{mean}, SUV_{max}, SUV_{peak} and total lesion glycolysis (TLG)) and robust texture uptake (entropy, homogeneity, SRE, LRE, LGZE and HGZE). **Results:** SUV_{max}, SUV_{mean} and SUV_{peak} tented toward increase between 3+3, 3+4 and >4+3 without significant statistical difference. Also, the texture parameters tended to decrease (homogeneity, LRE) or increase (SRE, HGZE) with growing Gleason score with significant statistical difference between 3+3 and >4+3 for SRE (**p**=0.025) and LRE (**p**=0.0182). With the receiver operating characteristic (ROC), the areas under curve (AUC) between groups 1/2, 2/3 and 1/3 were higher with homogeneity, SRE and LRE than with all intensity parameters, included significant statisti-

cal differences in 1/3 with SUV_{max} (homogeneity: **p**=0.0229; SRE: **p**=0.0280; LRE: **p**=0.0432). Neither intensity nor texture parameters were correlated with prostate specific antigen (PSA). **Conclusion:** To our knowledge, our study is the first to evaluate the texture analysis in prostate cancer in ^{18}F-Choline PET. Whereas we did not find significant difference between intensity parameters and the tumor differentiation according to the Gleason scoring, the texture analysis revealed two parameters (SRE and LRE) with significant difference between 3+3 and >3+4. This result shows that the texture analysis could be more predictive of the aggressiveness of prostate cancer than SUV. Furthers studies, with higher number of patients and comparison to the survival prognostic, are necessary to ensure the efficiency of texture analysis in prostate cancer in ^{18}F-Choline PET.

OP-246

SPECT-CT visualization of sentinel and second echelon lymph nodes for lymph flow guided radiotherapy of tongue cancer

S. Novikov, P. Krzhivitskiy, Z. Radzhabova, O. Ponomareva, M. Girshovitch, S. Kanaev; N.N. Petrov Institute Oncology, St Petersburg, RUSSIAN FEDERATION.

Purpose: to evaluate patterns of lymph flow from primary lesions in patients with tongue cancer and to determine how useful can be this information for radiotherapy planning. **Materials and Methods.** In 24 primary patients with tongue cancer we performed SPECT-CT visualization of sentinel and second echelon lymph nodes (LNs). SPECT-CT examination was performed 60-90 min after 4 peritumoral injections of 99mTc-nannocolloids (100-150MBq in 0.3-0.4ml). We determined the type of lymph flow (mono-, bilateral) and localization of all LNs with tracer uptake. Finally, status of regional LN was verified by histology and/or MRI with US. **Results:** Bilateral lymph-flow was detected in 14 of 25 (58%) evaluated patients. In 10 of 14 cases distance from medial sulcus to medial border of primary tumor was 4mm or less. Monolateral lymph-flow was mentioned in remained 10 patients (42%). In 9 of 10 cases distance from medial sulcus to primary lesion was above 4mm. In 5 of 24 patients (20.8%) LNs with 99mTc-nannocolloids uptake were localized only on Ib-IIa levels. In another 15 cases (62.5%) sentinel and second echelon LNs were visualized on level Ib-IIa-III. Wide distribution (Level Ia-IIa-III-IV-VI) of LNs with tracer uptake was mentioned in 4 (16.6%) cases. In 16 of 24 patients we revealed histological and /or instrumental (MRI plus US) signs of metastatic LN involvement. In all cases LNs with tracer uptake were localized on the same level and/or more distal. According to proposed strategy of lymph flow guided radiotherapy we irradiate regional LN that localized on the level of visualized sentinel and second echelon LNs. It means that in evaluated 24 patients this strategy would permit irradiation of all metastatic LNs revealed by histology and/or by MRI/US. In the same time irradiation volumes would be decreased in 75% cases. **Conclusion:** SPECT-CT visualization of lymph flow from tongue cancer can significantly influence extent of radiotherapy fields used for irradiation of regional LNs

OP-247

18F-FDG PET/CT radiomics in endometrial cancer

C. Crivellaro[1,2], E. De Bernardi[1], D. Vicini[1], F. Elisei[2], M. Cuzzocrea[1], A. Buda[3], E. De Ponti[4], F. P. Sina[3], L. Guerra[2], R. Fruscio[1,3], C. Landoni[1,2]; [1]University Milan-Bicocca, Monza, ITALY, [2]Nuclear Medicine, ASST-Monza, San Gerardo Hospital, Monza, ITALY, [3]Clinic of Obstetrics and Gynecology, ASST-Monza, San Gerardo Hospital, Monza, ITALY, [4]Medical Physics, ASST-Monza, San Gerardo Hospital, Monza, ITALY.

Background: 18F-FDG PET/CT is a diagnostic tool for staging endometrial cancer, in particular for nodal status assessment. **Objectives**: To evaluate the role of textural and geometric shape features extracted from 18F-FDG uptake of the uterine primary lesions in endometrial cancer. In particular, we investigated if these features, inserted in a clinical model, can predict recurrence and nodal metastases by using a machine learning technique. **Methods:** 85 patients with early stage endometrial cancer who underwent preoperative PET/CT scan followed by surgery were considered. Histological and clinical data were collected. Endometrial lesions were contoured with PETVCAR (GE Healthcare) and the following parameters were extracted: SUVmax, SUVmean, MTV, TLG, 6 geometrical shape and 64 textural features (computed by CGITA software). For recurrence analysis, only patients with a follow-up longer than the maximum recurrence time (35 months) were considered. Univariate analysis for association between features and recurrence/LN metastases was performed by Mann Whitney test; the correlation between features was investigated by Spearman rank test. Two neural network multivariate models were developed to predict recurrence and LN metastases. A stepwise backward feature selection scheme was adopted and neural networks were assessed with a leave one out approach on 10 training sessions. **Results:** Recurrence rate was 29% (15/51) patients. Univariate analysis found 16 PET-features correlated with recurrence ($p<0.05$). At multivariate analysis, a 2 layers neural network with 3 inputs (myometrium invasion, Zone percentage-GLSZM and Maximum of the texture Spectrum) can predict recurrence with a sensitivity of 73% +/-4% and with a specificity of 83% +/- 1%. Nodal metastases were found in 14/78 (20%) patients submitted to lymphadenectomy. Sensitivity and specificity of PET/CT in detection of nodal metastases resulted 50% and 90%, respectively. MTV and 28 PET-features were associated with LN metastases ($p<0.01$). A 3 layers neural network with 2 inputs (Zone percentage-GLSZM and Entropy-GLCM) resulted able to predict LN metastases with a sensitivity of 50%+/-8% and a specificity of 90% +/-1%. Combining PET/CT findings at nodal level and the neural network, sensitivity resulted 83%+/-6% and specificity 88%+/-1%. **Conclusions:** In endometrial cancer, the combination of PET textural features of primary lesion and histological data can predict the presence of recurrence. Although the known role of PET/CT in nodal staging, textural features may have ad additional value in predicting nodal metastases. These preliminary data suggest a promising application of radiomics in endometrial cancer; further studies on larger populations are needed.

Low Dose Radiation 18F-Fluoride PET/CT in the assessment of Unilateral Condylar Hyperplasia of the mandible: preliminary results of a 16 patients single centre experience

G. M. Lima, S. Diodato, E. Costabile, D. Calabrò, F. Scalorbi, A. Svirydenka, G. Cicoria, S. Civollani, C. Pettinato, P. L. Guidalotti, C. Nanni, S. Fanti; S. Orsola-Malpighi University Hospital, Bologna, ITALY.

Aim: Unilateral condylar hyperplasia (UCH) of the mandible, or Hypercondylia, is a pathological condition that determines an abnormal growth of the affected condyle. Tc99m-diphosphonates Bone SPECT is a successful tool in the assessment of UCH. EANM guidelines also suggest the use of 18F-NaF PET/CT, though it leads to a higher radiation exposure. As UCH patients are young, we aimed to compare a low-injected activity 18F-Fluoride PET/CT scan to a standard-injected activity scan in terms of image quality in the evaluation of UCH. **Materials and Methods**: We prospectively enrolled 16 patients (6 males, 10 females, mean age 24.5) with UCH, who underwent 18F-NaF PET/CT to assess the hypercondylia. We administered a low activity of 18F-NaF (185 MBq) in 5 patients and a standard activity (370 MBq) in 11 patients. Activity range was chosen according to 2015 EANM guidelines. One hour after injection, a single-bed

10 minutes PET acquisition from the glabella to the chin and an attenuation correction CT were performed. To determine if the scans with low radiotracer activity were "diagnostic" such as those with standard activity, three expert nuclear medicine physicians, unaware of the administered activity, reviewed the scans and expressed a final qualitative judgment in terms of "diagnostic"/"non-diagnostic" scan. Furthermore, we compared the effective dose of a low-injected activity PET/CT to the standard one and to a Bone SPECT performed with standard-injected activity of Tc99m-diphosphonates. **Results:** Reviewers classified all scans of both groups as "diagnostic". The effective dose of a 18F-Fluoride PET/CT is about 5.0 mSv [(0.024 mSv/MBq x 185MBq) for PET + 0,15 mSv for low dose CT] in scans performed with 185 MBq and about 9.0 mSv [(0.024 mSv/MBq x 370MBq) for PET + 0.15 mSv for low dose CT] in ones performed with 370MBq. The effective dose of 99mTc-MDP bone SPECT is about 4.3 mSv [0.0057 mSv/MBq x 740 MBq of Tc99-MDP]. **Conclusion:** 18F-NaF PET/CT performed with a low radiotracer activity allows a good assessment of UCH similar to that performed with an ordinary activity. The effective radiation dose of a low-injected activity PET/CT is significantly lower than an ordinary-injected activity PET/CT and is not significantly higher than the most used Bone SPECT. The 18F-Fluoride PET/CT procedure could be performed with 185MBq to minimize the effective radiation dose received, maintaining the quality of the scan. Further studies including a larger number of patients and clinical follow-up are needed to confirm our preliminary findings.

OP-253

Diagnostic ability of bone scan index for differentiating dental diseases

S. Watanabe, K. Nakajima, N. Noguchi, S. Kawashiri, A. Mizokami, M. Inokuchi, S. Kinuya; Kanazawa University Hospital, Kanazawa, JAPAN.

Purpose: Osteonecrosis of the jaw (ONJ) is a significant side effect of antiresorptive and antiangiogenic drugs prescribed for advanced cancer patients. We have reported that a quantitative diagnosis of bone scintigraphy using bone scan index (BSI) was useful for the early detection and risk assessment before the development of stage 2 antiresorptive agent-related ONJ (ARONJ). However, common dental diseases also cause positive tracer uptakes in the jaws. The aim of this study was to validate a diagnostic ability of BSI for differentiating ARONJ from common dental diseases. **Methods:** We evaluated 147 patients who underwent both bone scintigraphy and dental examination at our hospital retrospectively. In the control group, all 130 patients underwent dental examination within 3 months of the bone scintigraphy between January 2014 and December 2014. We excluded patients who developed ARONJ. In the ARONJ group, all 17 patients were diagnosed as stage 2 ARONJ between June 2007 and March 2016 and underwent bone scintigraphy 3 months (the average 2.8±1.9 months) before the first diagnosis of stage 2 ARONJ. Dental conditions were evaluated in four blocks, namely, upper or lower jaw, and right or

left region. The tracer uptake in each block was analyzed by BSI. The software BONENAVI (FUJIFILM RI Pharma; EXINIbone, EXINI Diagnostics) could automatically detect abnormal intensities and calculate each regional BSI (rBSI). Among the rBSI, the largest one in each block was manually selected and defined as maximum BSI of the jaw (BSIJmax). We compared the BSIJmax with the dental examination, as a gold standard. Results: In the control group, mild periodontitis, severe periodontitis, apical periodontitis, and dental caries were observed in 47 blocks, 7 blocks, 13 blocks, and 19 blocks, respectively, and the average BSIJmax were 0.03±0.02, 0.05±0.03, 0.03±0.03, and 0.04±0.04, respectively. Dental extraction was performed in 13 blocks before the bone scintigraphy, and the average BSIJmax was 0.06±0.05. In the ARONJ group, stage 2 ARONJ was subsequently observed in 22 blocks, and the average BSIJmax was 0.11±0.09, 3 months before the diagnosis. The BSIJmax was significantly higher in blocks where ARONJ was subsequently observed than in blocks where common dental diseases were observed (p < 0.005). However, there was no significant difference in BSIJmax between blocks where ARONJ was subsequently observed and blocks where dental extraction was performed (p = 0.06). **Conclusion:** BSIJmax could differentiate ARONJ from common dental diseases and be useful for the early detection and risk assessment of ARONJ.

OP-254

Influence of 18F-FDG-PET/CT on therapeutic decision-making of patients with spondylodiscitis

A. Pöllmann, D. Moskopp, M. Plotkin; Vivantes Klinikum im Friedrichshain, Berlin, GERMANY.

Introduction: Inflammatory diseases of the spine may be difficult to diagnose using morphologically oriented imaging methods (MRI, CT). 18F-FDG-PET/CT has proposed as an additional tool for the detection of spondylodiscitis (SD). We examined the extent to which PET/CT affected treatment decisions in patients with SD. **Methods:** Electronic medical records of 58 patients from the period 07/2011 - 03/2015 who were examined at Vivantes Institut für Nukelarmedizin were evaluated retrospectively. The patients were divided into two sub-groups: the first group (n = 34) included all patients who were examined with PET/CT under the tentative diagnosis of SD. In the second group (n = 24) with pre-diagnosed inflammatory spinal disease (SD and/or epidural abscess), PET/CT was performed to search for an occult infection focus. We evaluated to what extent the PET/CT had an impact on the therapeutic decision-making (high, medium or low). **Results:** Group 1: PET/CT showed SD in 16/34 patients and a liver abscess in one patient. PET/CT was negative in 17 patients. The impact of PET/CT on the therapeutic decision was classified as follows: 17/17/0 (high/medium/low). For 17/34 patients MRI data were available; in the remaining patients an MRI scan could not be performed (implanted pacemaker, obesity, claustrophobia). 15 of this MRI scans were negative for SD, two showed unclear findings. In the patients with negative MRI, PET/CT showed SD in 6 cases. Of the patients with unclear MRI results, one PET/CT discovered SD. Group 2: PET/CT lead to sub-

stantial findings (previously unknown infection focus or findings suspicious for malignancy) in 4/24 patients. The impact of PET/CT on the therapeutic management was classified as follows: 04/04/16 (high/medium/low). **Discussion:** ^{18}F-FDG-PET/CT is a valuable additional diagnostic tool in the primary diagnosis of spondylodiscitis and should be used in particular when an MRI scan of the spine is contraindicated, shows unclear results or if SD is still probable in spite of negative MRI. PET/CT is not helpful for detection of inflammatory focuses in patients with already diagnosed inflammatory spinal diseases, and depicts previously unknown lesions in rare cases.

OP-255
SPECT/CT imaging in Bertolotti's Syndrome

K. Bayardo[1,2], V. Depons[2], J. Vilar[1,2], D. Muñpz[1], A. Battegazzore[2], A. Silveira[2], R. Ferrando[1,2]; [1]Clinics Hospital, University of the Republic, Montevideo, URUGUAY, [2]Ferrari Ferrando Páez Nuclear Medicine Clinic, Montevideo, URUGUAY.

Introduction: Lumbosacral transitional vertebrae (LSTV) are common congenital anomalies of the lumbosacral segment present in 3%-21% of humans. The transitional vertebra may have different morphology ranging from broadened elongated transverse processes, often unilateral, to complete fusion to the sacrum. Inaccurate identification of LSTV may lead to surgical and procedural errors and poor correlation with clinical symptoms. The relationship between low back pain and LSTV (Bertolotti's syndrome) has been debated but pain may arise from varying levels and L5 sacralization can contribute to the development of orthopedic diseases. The Castellvi classification system describes four types of LSTV with increasing levels fusion (I-IV) and unilateral (a) or bilateral (b) dysplastic transverse processes. LSTV are difficult to recognize in SPECT images and currently CT is the best imaging technique for characterization of this entity. The objective was to describe SPECT/CT findings in patients with LSTV and low back pain. **Subjects and Methods:** The study population included 63 consecutive patients (35 female), with a mean age of 22 years (range 8-49), who underwent SPECT-CT imaging in our institutions in which a LSTV was identified. Low back pain was present in all but two patients. Patients older than 50 years were excluded. **Results:** CT images identified 18 type Ia LSTV, 4 type Ib, 21 IIa, 8 IIb, 1 IIIa, 9 IIIb, and 2 type IV with SPECT showing associated increased uptake in 52 patients. Six of the 11 cases with negative SPECT had type IIIB LSTV, in which increased uptake is less likely because of bilateral complete fusion. The other cases were 4 type I and 1 IIb. The remaining type III LSTV had only mild uptake at the the vertebral body transition. All type II LSTV and 1 patient with type IV had more intense lateralized incresed uptake associated with incomplete fusion. Moderately increased sacroiliac joint uptake was present in 9 patients and facet joint uptake in 3. Associated anatomical anomalies included incomplete vertebral fusion in 3 patients and disc herniation in 2. **Conclusion:** Hybrid imaging with SPECT/CT provides a new scenario for the characterization of LSTV. Specific morphological features can be recognized while the presence of stress in the lumbosacral

transition or neoarticulation can be detected, as well as associated reactions in facet and sacroiliac joints. Bertolotti's syndrome should always be considered in radionuclide studies assessing low back pain, particularly in young patients. SPECT/CT provides new cues supporting the syndrome.

OP-256
Scintigraphy of rhabdomyolysis - cornerstone in patient management?

D. Jocius[1], D. Vajauskas[1], A. E. Tamosiūnas[1,2], A. Skrebunas[1], M. Gutauskas[1]; [1]Vilnius University Hospital Santaros Klinikos, Vilnius, LITHUANIA, [2]Vilnius University, Vilnius, LITHUANIA.

Introduction: 99mTc MDP (99mTc methylene diphosphonate) is used as a diagnostic agent in both benign and malignant bone conditions. 99mTc MDP and other phosphonates are nonspecific tracers are used in osteoblastic bone lesion imaging and muscle necrosis imaging. When the cellular damage occurs pathophysiological mechanisms such as direct cell membrane damage or ATP (adenosine triphosphate) depletion leads to elevated intracellular calcium (Ca^{2+}) level which subsequently leads to cell apoptosis [1]. Such intracellular alteration elevates 99mTc MDP accumulation in the damaged site mimicking calcium deposition though enabling to image irreversible cell damage or cellular death such as muscle necrosis [2]. **Aim** The aim of this retrospective review is to evaluate the role of 99mTc MDP scintigraphy in assessing the site and extent of muscle necrosis. **Materials and Methods:** We retrospectively reviewed three year (2014-2017) results of 99mTc MDP scan performed in 14 patients with suspected limb muscle necrosis by elevated blood myoglobin concentration and clinical symptoms of rhabdomyolysis caused by several mechanisms. Further diagnosis was confirmed either by muscle biopsy if only fasciotomy was performed (2 patients) or after histological examination of resected surgical specimen: amputation (7 patients) or necrectomy (5 patients). **Results** Arterial disease was the leading cause of muscle necrosis, found in 12 patients and the remaining two patients acquired muscle necrosis due to positional compression syndrome. 99mTc MDP scan correctly showed increased pathological tracer uptake in limb muscle for all patients suggesting muscle necrosis which further was confirmed by histological examination in all cases. In addition hybrid SPECT/CT 99mTc MDP scan identified precise location and extent of affected muscles directing surgical treatment approach. **Discussion** Conservative management (meaning fasciotomy only) was chosen when only mild intramuscular tracer uptake in a small area was seen and while more aggressive surgical tactics such as necrectomy or limb amputation were performed in more severe cases with wide areas of tissue damage and high intramuscular tracer uptake. Special notification should be made for "cold" tracer uptake spots which probably were seen in avascular sites with total myolysis. **Conclusion** This retrospective study results shows that 99mTc MDP scan is effective diagnostic tool in describing muscle necrosis and showing the location and extent of damaged tissue. 99mTc MDP scan could be used as prognostic tool also directing the choice of treatment.

OP-257

Clinical relevance of 99mTc-HDP SPECT/CT in the diagnosis of spondyloarthropathies

A. Bakos[1], Z. Besenyi[1], S. Urbán[1], R. Hemelein[2], L. Kovács[2], L. Pávics[1]; [1]Department of Nuclear Medicine University of Szeged, Szeged, HUNGARY, [2]Department of Rheumatology University of Szeged, Szeged, HUNGARY.

Introduction: Spondyloarthropathies (SpA) belong to the group of inflammatory arthritis which comprises the ankylosing spondylitis, reactive arthritis, psoriatic arthritis/spondylitis, and arthritis/spondylitis associated with inflammatory bowel diseases. The early diagnosis is extremely important for starting appropriate therapy in time. Our aim is to examine the clinical significance of 99mTc-HDP SPECT/CT in diagnosis of early and chronic axial SpA. **Materials and Methods:** Thirteen patients (6 females, 7 males, mean age: 38,69 years) were involved into the study from 2016 July. The patients were selected from the Department of Rheumatology according to the clinical features. Firstly, we performed examination of the sacroiliac joint with MRI in the following sequences: T1- weighted STIR for the bone marrow oedema (BME) and T2-weighted sequence for the fat metaplasia (FM). The HDP SPECT/CT was used within one week to examine the sacroiliac joint. Thereafter, the MRI images were fused with SPECT/CT images. On the MRI images the BME (active lesion) and FM (chronic lesion), on the CT scans the sclerotic lesions (SCL, chronic lesion) were drawn manually as volume of interest (VOI). Uninvolved cortical areas were drawn on the different modality slices as reference region (ref). Then, we determined the isotope (99mTc-labelled HDP) uptake of the different lesions and areas (mean counts/VOI): VOI_{BME}/VOI_{ref}, VOI_{FM}/VOI_{ref}, VOI_{SCL}/VOI_{ref}. **Results:** Four active sacroileitis and five chronic sacroileitis without active lesions were diagnosed according to the MRI results. On the other 4 patient's sacroiliac joints images (MRI, scintigraphy, CT scans) there were not any pathological lesions. Nineteen lesions of 13 patients were localised on the fused MRI-SPECT/CT images: 6 BME, 4 FM and 9 SCL lesions. The isotope uptake of BME was the highest (VOI_{BME}/VOI_{ref}: 2,43). The radiopharmacon uptake of sclerotic lesions was moderate (VOI_{SCL}/VOI_{ref}: 1,76). The isotope uptake of FM lesions was not different from the HDP uptake of reference regions (VOI_{FM}/VOI_{ref}: 0,96). **Conclusion:** MRI is established modality in diagnosis of axial SpA. According to the initial results, the different MRI lesions have different isotope uptake, which suggests, that the HDP-SPECT/CT can distinguish the early and chronic stage of axial SpA.

OP-258

Increased Uptake in Synchondrosis of the Lower Limbs: Added Value of SPECT/CT.

K. Bayardo[1,2], A. Zamora[1], J. Vilar[1,2], R. Ferrando[1,2]; [1]Clinics Hospital, University of the Republic, Montevideo, URUGUAY, [2]Consultorio de Medicina Nuclear Ferrari Ferrando Páez, Montevideo, URUGUAY.

Introduction: Synchondrosis is the development of a union between two bones by hyaline cartilage that mostly represents a temporary joint present during the growth phase. Usually the fusion is asymptomatic, but sometimes children may have pain resulting in limitation of movement that is nonspecific and create problems in the differential diagnosis of equivocal findings on plain radiographs.99mTc-MDP is absorbed on freshly built bone tissue like synchondrosis in the obliteration process. SPECT/CT can identify physiological uptake and better characterize equivocal lesions increasing specificity. The aim of the study was to evaluate the diagnostic utility of SPECT/CT in children and adolescents with asymmetric uptake in painful or asymptomatic synchondrosis of the lower limbs. **Subjects and Methods:** All bone scans performed in the last 5 years in our institutions in patients aged 5 to 20 years were reviewed and 9 patients (8-17 years-old, 8 male) with asymmetric or unexpected increased uptake in synchondrosis of the lower limb were identified. Bone scintigraphy included whole-body and SPECT/CT images in a GE Infinia Hawkeye 4 or a Mediso AnyScan 16 gamma camera. **Results:** Most frequently involved sites were ischiopubic junction and anterior inferior iliac spine, both of them in 3 cases. Local pain was present in one case of each. The patient with painful iliac spine had intense uptake corresponding to an avulsion fracture on CT images, and associated mildly increased uptake on the contralateral ischiopubic synchondrosis. The other patients had mild to moderate uptake correlated with swelling of the synchondrosis with a lucent expansive appearance that has been described radiographically during normal ossification. Three of the 5 patients with uptake in synchondrosis of the hip associated spondylolysis and one had a lumbosacral transitional vertebra, potentially leading to excessive weight bearing on one side with asymmetric closure of the ipsilateral synchondrosis. Two patients presented with foot pain. One had a type II accessory scaphoid and the other had a bilateral os trigonum syndrome with left predominance. Intensity of uptake was moderate in both patients. The last patient presented pain and swelling of the tibial tuberosity with moderate to intense uptake corresponding to Osgood-Schlatter disease. **Conclusion:** SPECT/CT can identify synchondrosis in the obliteration process with different levels of uptake in relation to clinical evolution and localization. Hybrid images help to recognize the normal and abnormal variants, excluding differential diagnosis like osteomyelitis or neoplastic lesions and avoiding high dose CT or more expensive high resolution studies.

OP-259

SPECT/CT is equivalent to diffusion-weighted MRI in characterizing equivocal osseous lesions detected by planar bone scintigraphy

M. Khalil[1], Y. G. Abdelhafez[1], H. Atta[1], A. A. Kandeel[2]; [1]South Egypt Cancer Institute, Assiut University, Assiut, EGYPT, [2]Faculty of Medicine, Cairo University, Cairo, EGYPT.

Aim: To evaluate the diagnostic performance of 99mTc-MDP bone scintigraphy using SPECT/CT in comparison to diffusion-weighted (DW) MRI in patients with solitary osseous lesions detected on planar bone scintigraphy. **Methods:** This ongoing prospective study recruited 46 cancer patients referred for bone

scintigraphy (staging/restaging/follow-up). Their planar whole body scan showed solitary equivocal osseous lesion. Each patient further underwent SPECT/CT (same day) & DW-MRI (12 ± 16 days after bone scan date). Studies were read independently by one experienced nuclear medicine physician and one experienced radiologist on a 5-point score: (score 1 = benign, score 2 = likely benign, score 3 = equivocal, score 4 = likely malignant and score 5 = malignant). The final diagnosis of disease status was made on the basis of subsequent clinical/imaging follow-up for at least 6 months. **Results:** In the 46 patients evaluated, 16 (35%) lesions proved to be osseous metastasis while 30 (65%) remained disease free. SPECT/CT vs DW-MRI showed sensitivity, specificity, positive predictive and negative predictive values of 75% vs 63%, 77% vs 77%, 63% vs 59%, 85% vs 79% and 83% vs 72%; respectively. Both modalities were true positive (TP) in 7 lesions, and false negative (FN) in 1 lesion. SPECT/CT correctly identified disease in 5/6 FN lesions on DW-MRI, compared to 3 FN on SPECT/CT that were correctly diagnosed by MRI. Both modalities were true negative (TN) in 18 and false positive (FP) in 2 lesions. SPECT/CT excluded disease in 5/7 FP lesions on DW-MRI and the same did DW-MRI in 5/7 FP lesions on SPECT/CT. No statistically significant difference noted in sensitivity or specificity. ROC analysis showed area under the curve (AUC) of 0.84 (95%CI: 0.71-0.93%) for SPECT/CT compared to 0.67 (95%CI: 0.51-0.79) for DW-MRI; respectively (P = 0.1). No significant difference in diagnostic performance indices was noted for either axial (n = 29) or appendicular skeletal lesions (n = 17). **Conclusions:** SPECT/CT may perform, at least, equal to MRI with diffusion in characterization of equivocal solitary osseous lesions detected on planar whole body skeletal scintigraphy.

Ultra-low Dose CT for Attenuation Correction of 82Rb Cardiac PET

M. B. Sørensen, K. Bouchelouche, L. P. Tolbod; Dept. Nuclear Med. & PET-Centre, Aarhus University Hospital, Aarhus, DENMARK.

Aim: Myocardial perfusion imaging (MPI) using cardiac PET with tracers like 82Rb and 15O-water is substantially lower in radiation dose than classic MIBI-based SPECT. However, for cardiac PET, the dose contribution of CT for attenuation correction (CTAC) is typically 20-30% of the total dose. To reduce the total radiation dose of cardiac PET further, we set out to examine if the use of ultra-low dose CTAC (UL-CTAC) would affect the accuracy of the quantitative parameters related to MPI. Furthermore, we examined whether the low quality of the UL-CTAC would affect the technologist's ability to perform manual adjustment for misalignment between PET and CTAC. The CT reconstruction algorithm Q.AC was used to improve quality and consistency of the CTAC. **Method:** 23 consecutive clinical patients (BMI: 26.9 [range: 15.4-38.8]) referred for 82Rb PET rest and stress imaging were included in the study. All patient received both a normal dose CTAC (120 kVp, 0.5s rotation, 10-100 mA (Smart mA), Noise Index 46) and an UL- CTAC (100 kVp, 0.7s rotation, 10-40 mA (Smart mA), Noise Index 125) prior to the rest PET scan. The same CTAC was used for correction of both rest and stress scans. Manual adjustment for misalignment between PET and CT was performed independently for both CTAC and UL-CTAC. Data was analyzed using QPET (Cedar Sinai). Static uptake images were analyzed (%Summed Scores, %Extend, %Reversible and Total Perfusion Deficit (TPD)), and parameters were compared by using scatter plots and linear regression. CTAC radiation dose was estimated from Dose Length Product using a conversion factor of 0.014 mSv/(mGy cm). All patients were scanned on a GE Discovery MI Digital Ready PET/CT. PET images were reconstructed using Time-of-Flight, Resolution Recovery, attenuation and scatter corrections. **Results:** CTAC dose was reduced from 0.5 mSv [range: 0.1-1.1] to 0.11 mSv [range: 0.1-0.2]. Manual adjustment for misalignment between PET and CTAC was performed without any difficulties on all images. Excellent correlation between normal dose CTAC and UL-CTAC was found for all MPI parameters (Summed Scores: y=0.96x+0.02, R2=0.95; %Extend: y=0.99x+0.80, R2=0.97; %Reversible: y=0.86x+0.84, R2=0.94; TPD: y=0.99x+0.76, R2=0.97). **Conclusion:** The CTAC dose was reduced from 0.5 mSv [range: 0.1-1.1] to 0.11 mSv [range: 0.1-0.2]. Excellent correlation between the normal dose CTAC and UL-CTAC was found for the quantitative parameters related to MPI. Therefore, it seems possible to use a UL-CTAC without affecting the quantitative accuracy.

OP-272

Pediatric Anesthesia on Daily PET/CT workflow:Impact Quantification Based on Three Indicators

C. Barbosa[1], S. Mendes[1], I. Ferreira[1], P. Gil[1], P. Ribeiro[1], G. Costa[1,2], J. Pedroso de Lima[1,2,3]; [1]Centro Hospital e Universitário de Coimbra (CHUC), Coimbra, PORTUGAL, [2]Faculdade de Medicina da Universidade de Coimbra, Coimbra, PORTUGAL, [3]Instituto de Ciências Nucleares Aplicadas à Saúde, Coimbra, PORTUGAL.

Aim: 18F-FDG-PET/CT is an important method for assessing a wide variety of pathologies in any age group. Children bring special challenges to Nuclear Medicine Departments and, in some cases, the use of anesthesia must be considered. However, the specificities of the anesthesia protocol tend to extend the occupation of PET/CT's imaging room. In that context, we aimed to quantify the impact of the anesthetic procedure performed in children on the PET/CT workflow using three measurable indicators: 1) child 18F-FDG uptake period; 2) 18F-FDG uptake period of the next patient; 3) "interpatient time" defined, in this context, as the period elapsed between the end of the child PET/CT imaging acquisition and the beginning of PET/CT of the next patient. **Material and Methods**: We collected data on 18F-FDG uptake period for all pediatric patients submitted to anesthesia in our department, between April 2013 (the beginning of collaboration with the Anesthesiology Department) and February 2017. "Interpatient time", according to the above-stated definition, and the 18F-FDG uptake period of the patient immediately schedule after the child were also recorded. Finally, the averages of each one of those three indicators were calculated and compared with the corresponding time periods obtained in a regular workday, without anesthetic support. The age of the children, gender and the modality of PET/CT (brain or whole-body) were collected. **Results:** Of the 27 PET/CT examinations performed under anesthesia, 17 were brain studies (5 girls,12 boys; mean±sd age=7.5±4.8 years) and 10 were whole-body scans (9 girls,1 boy; mean±sd age=3.2±1.6 years). The 18F-FDG uptake time for anaesthetized children had a mean±sd of 01h17min±14min and for the following patient (without anesthesia) of 01h21min±19min. These periods are longer than those observed on a regular workday (01h06min±12min), without anesthetic support. The "interpatient time" was 22min±10min, also significantly longer when anesthesia was not performed (5min±2min). **Conclusion**: Anesthesia enables the acquisition of PET/CT imaging in uncooperative and unwilling children. However, is a time-consuming procedure that requires, in average in our Department, 28 additional minutes for each examination preformed under anesthesia (11min+17min for respectively 18F-FDG uptake and "interpatient time"). The quantification of the impact of anesthesia in the workflow, will help us to adjust the patients appointment intervals and the respective 18F-FDG administration timing on the days that include examinations under anesthesia.

OP-273

18F-FDG PET/CT in pediatric lymphoma patients: the role of technologist

M. Ciaccio[1], C. Nava[2], D. Bonacina[1], M. Maurizio[1], A. Perri[1], A. Renaioli[1], S. Morzenti[3], L. Guerra[1], C. Crivellaro[1,2]; [1]ASST-Monza, San Gerardo Hospital, Nuclear Medicine, Monza, ITALY, [2]University

Milan-Bicocca, Nuclear Medicine, Monza, ITALY, [3]ASST-Monza, San Gerardo Hospital, Medical Physics, Monza, ITALY.

Background: The increasing use of serial 18F-FDG-PET/CT scans in lymphoma pediatric patients raises the issue of radiation exposure. Recently, PET/CT scanners with high sensitivity allow to reduce both injected FDG-activity and CT amperage ("Low-dose" protocols) without compromising diagnostic accuracy. **Aim:** Aims of this study were: 1) to retrospectively compare dosimetric exposure of pediatric lymphoma patients submitted to serial PET/CT scans, comparing the Low-Dose vs Standard protocols, 2) to evaluate the approach of the technologist during PET/CT scan. **Methods:** Standard protocol was performed in 22 lymphoma patients by using Discovery600 (GE Healthcare) with 3,7 MBq/kg of injected activity, 2 minutes/FOV, 120kV and 40mA for CT. Low-dose protocol was performed in 8 patients scanned by DiscoveryIQ (GE Healthcare) with large axial FOV (26cm) and high-sensitivity, with 1.85 MBq/Kg, 3 minutes/FOV, 120kV and 25mA for CT. Radiation exposure calculated by ICRP 106 and by CT-expo 1.6 for PET and CT respectively, were there compared. Technologists' approach in the different phases of PET/CT and potential advantages in performing contrast-enhanced CT in a single session examination were observed. **Results:** Overall, a mean of 3 PET/CT per-patient were performed (range 2-13). The mean effective dose for PET study resulted 5.89mSv and 2,6mSv for standard and low-dose protocol, respectively (p <0,0001). The mean effective dose of CT study was 3,9mSv and 3,1mSv for standard and low-dose protocol respectively. The mean cumulative dose/patient was 31.3mSv and 18.79mSv for standard and low-dose protocol respectively. According to Biological Effects of Ionizing Radiation VII report, the risk of incidence of a second tumor for a 10-years-old male and female patient resulted 0.45/100 and 0.81/100 for standard protocol whereas the same figures were 0.22/100 (male), 0.49/100 (female) for low-dose protocol. The relationship between technologist and children is based on verbal and nonverbal communication from the acceptance of children and their parents till their dismissal. If both required, performing PET/CT and contrast-enhanced CT in a single session examination (if both required) can reduce distress for the patient, as it means a "single stressor" instead of 2 (single access to hospital, single ago-cannulae, single medical-team). **Conclusion:** The radiation exposure from serial PET/CT studies in pediatric lymphomas can be considerable. Low-dose protocols can be a valid tool to reduce radiation exposure in pediatric population without sacrificing diagnostic information. Technologists, using individual skills, have an important role in the optimization process and in patient management.

OP-274

Practical Guide for ^{18}F-Choline PET Imaging in hyperparathyroidism

M. Hofbauer, J. Trinckauf, M. Hüllner; UniversitätsSpital, Zurich, SWITZERLAND.

Purpose/Introduction: Primary hyperparathyroidism (PHPT) is the third most common endocrine disorder, with a prevalence of 0.1-1.0%. The main cause of PHPT is a solitary parathyroid adenoma (80% - 85%). There is evidence that PET imaging using ^{18}F-choline, especially in patients with negative or discrepant SPECT and ultrasound has an excellent diagnostic performance and yields promising results in the detection and correct localization of parathyroid adenomas. The aim of this presentation is to provide practical guidance for technologists using PET/CT and PET/MR scanners for the diagnostic work-up of hyperparathyroidism. **Materials and Methods:** Exams were performed on an integrated PET/MR scanner (GE Signa 3.0T) or on a sequential PET/CT+MR scanner (GE trimodality PET/CT D690 and MR 750w 3.0T). In total, more than 100 patients were scanned in one of the two modalities. After the injection of 150 MBq ^{18}F-choline, two PET datasets were acquired (early and late phase). In between a diagnostic MR scan of the neck was performed. The acquisition time for PET/CT+MR was approximately 75 minutes, while the PET/MR protocol was acquired within 45 minutes. **Results and Conclusion:** This practical guide helps technologists acquire knowledge on ^{18}F-choline PET imaging in patients with suspected parathyroid adenomas. PET/CT+MR procedure as well as PET/MR procedure, including acquisition parameters and dedicated MR pulse sequences along with pertinent work flow will be presented in a step-by-step manor. It is shown that the simultaneous PET/MR scan results in a time reduction of approximately 40% compared to the trimodality set-up, which is important for implementation in clinical routine.

OP-275

^{68}Ga-PSMA PET/CT Protocol Review

E. Poel; Academic Medical Center, Amsterdam, NETHERLANDS.

Aim: The aim of this study is to optimize the ^{68}Ga-PSMA PET/CT protocol, including the CT parameters. **Methods:** 4 academic medical centrums from the Netherlands, 1 from Belgium ,1 from Germany and 1 specialized oncological centrum from the Netherlands has been asked to share their ^{68}Ga-PSMA PET/CT scan protocol. Also PubMed, the online scientific articles' database, was consulted where the keywords "PSMA" and "PET" were used to find relevant articles. The protocols were compared to the literature. **Results:** A large difference in CT parameters is seen in de choice between a low dose CT scan (30-60 mAs) without intravenous contrast and a high dose CT scan (120-180 mAs) with intravenous contrast. Other differences are seen in PET parameters. The dose of PSMA is varying between 1,5 MBq/kg - 2,2 MBq/kg and a standard dose of 100 MBq ^{68}Ga-PSMA. The scan time per bed position variates from 2-4 minutes. All protocols prescribes that patients should be well-hydrated before the study and during the uptake time The use of Lasix is different between none use, 10 mg and 20 mg. Most hospitals start the PET/CT scan 1hr p.i. In the literature is found that an extra scan 3 hr p.i. is helpful to detect more prostate cancer lesions. **Conclusion:** The most ideal protocol will exist of 2 ^{68}Ga-PSMA PET/CT scans , 1hr p.i. and 3hr p.i. The 1hr p.i. scan low dose from the skull base to upper legs and the 3hr p.i.scan high dose of the pelvis and abdomen with intravenous contrast. 20mg of Lasix should be applied 30min prior to the late scan. The patients

should be well-hydrated before the study and during the up-take time. The best combination of dose 68Ga-PSMA and scan time per bed position should be researched in further investiga-tion and depends of the used PET/CT.

OP-276
Reducing artefacts in PSMA PET/MR due to hip prosthesis with MAVRIC SL

T. Oblasser, M. Hofbauer, J. Trinckauf, T. Berthold, K. Friedrich, I. Burger; Department of Nuclear Medicine, PET/ CT - MR Zentrum für Klinische Forschung, UniversitätsSpital Zür, Zurich, SWITZERLAND.

Aim: Metal Artefacts in PET/MR Examinations reduce MR image quality and impair the attenuation correction (AC) which is nec-essary to deliver adequate PET images. The gradient echo se-quence acquired for tissue segmentation based MR AC is espe-cially vulnerable to susceptibility resulting in large signal voids around prosthesis. There are promising new MR sequences to reduce those artifacts around metal implants such as Multi-Ac-quisition with Variable Resonance Image Combination SeLective (MAVRIC SL). We investigated the potential reduction of signal voids due to hip prosthesis using MAVRIC on Prostate Specific Membran Antigen (PSMA) PET/MR scans. **Material and Meth-ods:** The examinations were performed on a SIGNA PET/MR (GE Healthcare, 3T MR Scanner). 7 consecutive patients referred for 68Ga-PSMA PET/MR (age 69.86 ± 7.56 years) with one or two hip prosthesis were included. For imaging of the prostate gland four sequences covering the pelvic region were analysed: an MR-AC sequence (0:23min) as the reference, a Dixon (Lava Flex) Sequence (00:18 min), a T1 weighted ax sequence (2:06min) and MAVRIC SL (3:41min). The largest signal void was selected on each sequence and measured in two dimensions. The rela-tive difference between MR AC and the three other sequences was calculated. **Results:** Comparing the Lava, T1 and MAVRIC SL with the MR AC Sequence all of them showed substantial-ly reduced artefacts. For the LAVA Sequence the mean reduc-tion was 11.12% ± 17.48%, the mean reduction for the T1 was 22.98% ± 13.91% and the MAVRIC SL Sequence showed a mean reduction of 65.05% ± 10.08%. **Conclusion:** MAVRIC offers a fea-sible and relatively fast possibility to substantially reduce signal voids due to hip prosthesis for prostate PET/MR, improving MR image quality for the pelvis and potentially AC for PET.

OP-277
Improving alignment between 18F-FDG PET and CT scans by controling breathing movements during the CT-scan.

T. K. Lehnskov[1], C. P. Jønsson[2], L. B. Katz[2], D. A. Riisberg[2]; [1]Bispebjerg/Frederiksberg Hospital, København NV, DENMARK, [2]Metropolitan University College, København N, DENMARK.

Due to the short duration a lone standing CT-scan can be ob-tained during breath hold. However, when combined with a PET-scan it is not possible to perform the longer lasting PET acquisition during breath hold. The misalignment between PET and CT images is most pronounced in the lower thorax and

upper abdomen. **Aim:** The goal in the project was to train the patient during the CT scan to perform breath hold just at the end of expiration phase, in order better to align the CT-scan and PET-scans at a common level **Materials and Methods:** In our department we use a Varian system (Varian Medical Systems) to track the patient breath period under PET scanning. In conjunc-tion with a Q.Static software(GE Healthcare). With this system it is possible to perform post-hoc motion correction, where de-fined parts of the inspiration and expiration phases are deleted from the PET acquisition data. We considered several versions of breathing instructions before a CT-scan and ended by us-ing: *Breathe out gently and stop breathing*. The patients were trained to use this technique before the CT-scan. In addition they also used this breathing technique during Scout. All scan were performed on a GE Dsicorvery 710 PET/CT with the use of the Varian Breath tracking system and GE´s Q.static software. The patients we randomly CT-scanned either with or without voice instructions. The latter group consisted the control mate-rial. The Varian Breath tracking system, record all of their breath-ing movements during the CT- and PET-scan. **Results:** Fiftyone patients were included in the project. Twenty one patients were CT-scanned after voice instructions. The results showed an av-erage misalignment between PET and CT by 2.8 millimeters (Range 0.5 mm to 7.4 mm). The control group of 30 subjects showed an average misalignment by 7.19 mm (range 0.8mm to 9.8 mm). One patient was excluded because he could not collaborate according to the breathing instruction. **Conclusion:** By training the breathing technique with the patient just be-fore the CT-scan, it is possible to reduce misalignment between PET and CT-scans by approximately 60% (mean). In addition the CT-scan will be obtained during breath hold. We suggest that using this simple breathing training technique will improve the diagnostic quality of the PET/CT reading.

OP-278
Myocardium metabolic suppression protocol for 18F-FDG PET Sarcoid Scan

E. M. Bagi, A. Garcia-Campos, K. Wechalekar; Royal Brompton &Harefield NHS Foundation Trust, 77 WimpoleStreet, London, W1G 9RU, London, UNITED KINGDOM.

Introduction: 18F-fluorodeoxyglucose (FDG) PET has significant advantages in assessing disease activity and monitoring treat-ment response in patients with cardiac sarcoidosis. Normal myocytes utilize glucose as one of the major energy source, various techniques have been developed to suppress physio-logical 18F-FDG uptake in the heart to minimize false-positive results. 3 approaches have been tried: prolonged fasting, dietary modification and IV unfractionated heparin. The different proto-cols have reported varying success rates in achieving adequate metabolic suppression in the myocardium. We wanted to find out our own success rate with our protocol against this pub-lished data at our new establishment. **Method:** 100 consecutive patients underwent cardiac sarcoidosis protocol requiring 18h carbohydrate free diet followed by 18h fast (including diabet-ic patients); Dietary modification with a high-fat, high-protein

and no-carbohydrate diet was advised with menu suggestions. Diabetic patients were advised oral hypoglycaemic agents or insulin as routine until commencement of fast. Patients were informed about their preparation through a letter/email followed by a phone call during booking andat 24hprior to the scan. On arrival, patient's compliance was checked. If not, the examination was cancelled. Blood sugar level (BSL)was checked before the FDG injection with uptake time of 75mins.Half body scan (skull base-mid-thigh) with additional 10 min static acquisition of the heart on a Siemens Biograph mCT Flow scanner was acquired. Images were processed and reported on Syngo Via and Hermes software by experienced nuclear physicians. If the images showed homogeneously increase FDG uptake in the LV and RV myocardium, compliance failure was suspected and as such reported. **Results:** 100 consecutive patients were analysed: 36 (36%) women, age 54±14 years,21 (21%) diabetics (6 on insulin) mean weight 85±22kg, mean height 173±14cm. Overall mean BSL value was 5.1±1.0mmol/L; max BSL on diabetics was 8.3mmol/L and minimum was 3mmol/L.No patients needed to be cancelled due to symptomatic or reported hypoglycaemia. Good metabolic suppression of glucose in the myocardium was achieved in 99 (99%) patients and inadequate suppression was suspected in 1 (1%) diabetic patient. We did not have any symptomatic hypoglycaemia episode among diabetic or non-diabetic patients during their attendance. **Conclusions:** We report excellent patient compliance to cardiac sarcoidosis preparation protocol (99%) in our setting compared to other reported patient preparation protocols. This is achieved through patient education communication and compliance check to achieve good metabolic suppression of glucose from the normal myocardium. Diabetic patients compliedwell with this protocol.

OP-279

PET imaging with [45]Ti and the technical challenges involved

P. Costa[1], N. Arantes[2]; [1]Nuclear Medicine Department, ESS|P.Porto, Porto, PORTUGAL, [2]Independent Nuclear Medicine Technologist, Braga, PORTUGAL.

Introduction: Research has been made to test the use of unconventional PET radionuclides. Titanium-45 ([45]Ti) comes as a suitable option due to its favorable physical properties (half-life of 3.09h and positron maximum energy of 1040 keV) combined with chemical properties that allow radiolabeling of different compounds using chelation, opening new opportunities to develop new radiolabeled nanoparticles. However, the introduction of a new player into clinical routine presents some technical challenges that should be addressed. This work aims to discuss the potential role of PET imaging with [45]Ti, present and describe the best practices in this context, while addressing the opinion of Nuclear Medicine Technologists (NMT) on new imaging protocols regarding the best operating standards. **Materials and Methods:** Physical properties of [45]Ti with impact on image quality were explored using Monte Carlo simulation tools, while radionuclide production feasibility was studied in a low energy cyclotron (IBA® Cyclone 18/9). NMT's opinion was established

with the results of a survey conducted on a sample of 20 NMT's with different levels of education/training and professional experience. The survey included multiple choice questions and open answer questions. **Results and Discussion:** Experimental results demonstrate that producing [45]Ti in low energy cyclotrons is feasible. Preliminary insights regarding image quality suggest the suitability of this radionuclide to provide good PET image quality, at the same level of the one obtained using ^{11}C or even [18]F. Respondents of the survey present different insights on the necessary adjustment of technical procedures to obtain high-quality PET images. Correlation is established between professional experience on PET field, education level and their insights. Complete results of the survey will be presented and discussed, allowing to bring some topics to be addressed in future advanced education programs. Our proposal of guideline of good practices will be presented, highlighting suggestions of technical parameters regarding radionuclide production, radiopharmaceutical preparation, suggestions for administered activity and image acquisition protocols, finishing with radioprotection issues. **Conclusion:** NMT have indeed a crucial role in the implementation of new agents in the clinical routine of PET imaging. Apart from other examples that could be cited, [45]Ti could be considered an interesting option, being used in this work as a case study for the evaluation of the actual NMT's knowledge/opinion on the need of adequacy of procedures for the use of novel agents.

Feasibility of state-of-the-art PET/CT system performance harmonisation

A. Kaalep[1], T. Sera[2,3], S. Rijnsdorp[4], M. Yaqub[5], A. Talsma[6], M. A. Lodge[7], R. Boellaard[8,5,3]; [1]North Estonia Medical Centre, Tallinn, ESTONIA, [2]University of Szeged, Szeged, HUNGARY, [3]EANM Research Limited, Vienna, AUSTRIA, [4]Catharina Hospital, Eindhoven, NETHERLANDS, [5]VU University Medical Center, Amsterdam, NETHERLANDS, [6]Martini Hospital, Groningen, NETHERLANDS, [7]Johns Hopkins University, Baltimore, MD, UNITED STATES OF AMERICA, [8]University Medical Center Groningen, Groningen, NETHERLANDS.

Purpose: The aim of this study is to explore the feasibility of harmonising performance for different PET/CT systems equipped with the latest PET time-of-flight (ToF) and resolution modelling/point spread function (PSF) technologies. The second aim was producing a working prototype of new harmonising criteria with higher contrast recoveries than current EARL standards us-

ing various SUV metrics. **Methods:** Four latest generation PET/CT systems equipped with both time-of-flight and point spread function capabilities from 3 major vendors were used to acquire and reconstruct images of the NEMA NU2-2007 body phantom filled according to EANM EARL guidelines. A total of 15 reconstruction parameter sets of varying pixel size, post filtering and reconstruction type, with 3 different acquisition durations of 5, 2 and 1 minutes per bed position were used to assess and compare the quantitative performance of the systems. A target range for recovery curves was established such that it would accommodate the highest matching recoveries from all investigated systems. These updated criteria were validated on 18 additional scanners from 16 sites in order to demonstrate the scanners' ability to meet the new target range. **Results:** Each of the four investigated systems were found to be capable of producing harmonising reconstructions with similar recovery curves. The 5 reconstruction parameter sets producing harmonising results significantly increased SUV mean (24%) and SUV max (24%) contrast recoveries compared with EARL specifications currently in effect. Additional prospective validation performed on 18 scanners from 16 EARL accredited sites demonstrated the feasibility of updated harmonising specifications. Peak SUV parameter was found to significantly reduce the variability in quantitative results while producing lower recoveries in smaller (<22 mm) sphere sizes. **Conclusions:** Harmonising PET/CT systems with ToF and PSF technologies from different vendors was found to be feasible. The harmonisation of such systems would require an update to the current multi-centre accreditation program EARL in order to accommodate higher recoveries. SUV peak should be further investigated as a noise resistant alternative quantitative metric to SUV max.

OP-282

Feasibility of a brain PET harmonization program for state of the art PET/CT systems

R. Boellaard[1], S. Golla[2], A. Kaleep[3], M. Yaqub[2], T. Sera[4], S. Rijnsdorp[5], R. Kogan[1], N. Leenders[1], A. Lammertsma[2]; [1]University Medical Center Groningen, GRONINGEN, NETHERLANDS, [2]VU University Medical Center, Amsterdam, NETHERLANDS, [3]North Estonia Medical Centre Foundation, Tallinn, ESTONIA, [4]University of Szeged, Szeged, HUNGARY, [5]Catharina Hospital, Eindhoven, NETHERLANDS.

Purpose/Introduction: Use of brain PET studies in multicentre trials or as a quantitative imaging biomarker for (automated) differential diagnosis of neurogenerative diseases require harmonized quantitative image characteristics. In this study we explored the feasibility of developing a harmonizing performance standard for brain PET studies on state of the art PET/CT systems. **Subjects & Methods:** In this exploratory study 6 state of the art PET/CT systems were included: Philips Gemini TF, Ingenuity TF and digital Vereos systems, 2 Siemens Biograph mCTs and a GE 710. Only systems with EARL compliant (calibration and image quality) performances were included. A 30 min dynamic PET scan of the 3D Hoffmann brain phantom was acquired. The phantom was filled with an exact known FDG stock solution (aimed at 40 kBq/mL). Each scan was reconstructed

using various clinically relevant reconstruction settings. Depending on PET/CT system reconstruction settings were varied as follows: time of flight (TOF) on/off; resolution modelling (RM) on/off, voxel size, number of iterations/subsets and Gaussian smoothing FWHM (mm). The reconstructed images were analysed using a coregistered eroded binary map of both grey (GM) and white matter (WM). GM and WM recovery coefficients were calculated as the ratio of observed and expected activity concentrations. **Results:** For all systems distinct differences in both GM and WM recoveries and GM/WM ratios were observed between reconstructions that did or did not apply RM. Across the various systems/reconstructions a harmonized GM recovery between 0.77 and 0.85 (RM OFF) or between 0.81 and 0.94 (RM ON) seems feasible. WM recoveries (0.25 expected) were less affected by reconstruction settings, but showed a larger difference between Philips (0.28 to 0.33) versus Siemens (0.20 to 0.20) and GE (0.22 to 0.23) systems. GM/WM ratios were 4.2 to 4.4 for the Siemens and 3.7 to 4.0 for the GE systems, while the Philips systems showed somewhat lower values of 3.1 to 3.5 mainly because of difference in WM recovery. **Discussion/Conclusion:** Harmonization of PET/CT system performance for brain studies appears to be feasible, in particular for GM uptake assessment. Use of RM increases GM recovery at the cost of a wider (worse) harmonized performance range. There seems to be a vendor specific difference in WM recovery. The cause of this finding (possibly scatter correction) as well as its implication for PET/CT performance harmonization needs to be further explored. Currently, more data are being collected prospectively as part of JPND granted European networks.

OP-283

EANM/EARL FDG-PET/CT accreditation - summary results from the first 150 accredited imaging sites

*A. Kaalep[1], **T. Sera**[2,3], W. Oyen[4], B. J. Krause[5], A. Chiti[6,7], Y. Liu[8], R. Boellaard[9,10,3]; [1]North Estonia Medical Centre, Tallinn, ESTONIA, [2]University of Szeged, Szeged, HUNGARY, [3]EANM Research Limited, Vienna, AUSTRIA, [4]The Royal Marsden Hospital, London, UNITED KINGDOM, [5]Rostock University Medical Center, Rostock, GERMANY, [6]Humanitas University, Rozzano, ITALY, [7]Humanitas Research Hospital, Rozzano, ITALY, [8]The European Organisation for Research and Treatment of Cancer, Brussels, BELGIUM, [9]University Medical Center Groningen, Groningen, NETHERLANDS, [10]VU University Medical Center, Amsterdam, NETHERLANDS.*

Purpose: The European Association of Nuclear Medicine (EANM) has been running an FDG-PET/CT accreditation program under the EANM Research Ltd (EARL) initiative in order to harmonise quantitative performance of PET/CT systems, facilitate multi-centre trials and research. From 2010 until July 2016 EARL collected over 2500 phantom datasets from approximately 200 cameras and more than 150 imaging sites worldwide. The objective of this study is to report the findings and the impact of participating in the accreditation program on the standardisation and the quantitative variability of the investigated PET/CT systems. **Methods:** In order to obtain and maintain the EARL accredited status, sites were required to complete two distinct phantom scan proce-

dures - calibration quality control (CalQC) using a uniform cylindrical phantom and image quality control (IQQC) using a NEMA NU2-2007 body phantom, comprising 6 hot spheres with variable sizes. The CalQC and IQQC scans sent to EARL were analysed in a standard way, and average volumetric SUV bias and SUV recovery coefficients (RC) were calculated. In this study the EARL data were evaluated on the basis of quality control (QC) type, approval status, PET/CT camera manufacturer, and first and subsequent QC data submissions. **Results:** 5% (n=96) of all CalQC scan submissions (n=1816) demonstrated a measured SUV bias of more than 10%. Upon EARL feedback and after corrective actions, sites achieved 100% compliance within EARL specifications. Longitudinally, majority of the systems showed reproducibility within ±5% of the expected SUV. From IQQC scan submissions 30% (n=1381) of SUVmean and 23% (n=1095) SUVmax sphere recoveries failed to meet EARL accreditation criteria. After EARL accreditation, failure rate decreased to 12% (n=360) and 9% (n=254) respectively. A tendency towards positive bias was observed prior and also after EARL accreditation. Following the initial adjustment of the reconstruction parameters, the longitudinal reproducibility of the recovery values remained stable and generally within ±10% for largest 4 spheres and ±20% for smallest two spheres. **Conclusions:** Regardless of system manufacturer or model, all systems were able to comply with the CalQC and IQQC EARL specifications. Within the EARL accreditation program gross PET/CT calibration errors are successfully identified and longitudinal variability in PET/CT performances reduced by maintaining the QC experiments. The program is running successfully for more than 6 years and shows that a harmonising accreditation procedure is feasible and achievable.

OP-284

Development of the IAEA-NMQC toolkit for automated analysis of quality control tests on SPECT systems

G. L. Poli[1], *A. Vergara Gil*[2], *L. Torres Aroche*[2], *E. De Ponti*[3], *A. Kesner*[4]; [1]*International Atomic Energy Agency, Vienna, AUSTRIA,* [2]*Division of Clinical Research, Centre of Isotopes, Havana, CUBA,* [3]*Department of Medical Physics, ASST Monza, Monza, ITALY,* [4]*Memorial Sloan Kettering Cancer Center, New York, NY, UNITED STATES OF AMERICA.*

Purpose: Proper quality control (QC) procedures in SPECT play an essential role in ensuring optimized performance of imaging equipment, and are requisite for providing high quality clinical care. Because QC procedures are implemented routinely, streamlining them with automated software may offer several benefits: improved speed, reduced errors, and the standardization of calculation methods across centres. The purpose of this work was to develop a toolkit for supporting common SPECT QC data analysis procedures, and validate it using test images from multiple vendor systems and/or simulated images. **Materials and Methods**: We developed the IAEA-NMQC toolkit for performing the required image analysis of the SPECT QC procedures described in IAEA guidance documents and NEMA standards. The software is a collection of plugins which readily integrate with the freely available image analysis software

ImageJ. For validation, the plugins were tested using typical SPECT QC images acquired on machines which spanned different vendors: GE, Mediso, Philips and Siemens. The plugins were validated using test appropriate validation criteria. In some cases, software phantoms were generated and used to evaluate concordance of results with known truth. In other cases, results were compared with those from vendor software or other existing methodologies. For the plugins which are not fully automated and require some intervention by the user, the validation included inter- and intra-observer variability comparisons. **Results**: Automated and semiautomated functions were successfully developed to analyze multiple SPECT QC tests, including planar uniformity, sensitivity, spatial resolution and linearity, pixel size, centre of rotation, and tomographic uniformity, contrast and resolution. Where appropriate, measurement accuracy was assessed using "known truth" software phantoms, and in all cases results conformed to performance expectations. Validation using comparison of our plugins with standard methodologies revealed no statistically significant differences in the results. For the semi-automated tests, inter- and intra-observer variability was studied and no statistically significant differences were found. **Conclusion**: There is wide agreement that routine QC is an important aspect of any SPECT imaging program. While the field has well developed guidance for performing these tests, procedures for data analysis remain relatively established. In this work we present the IAEA-NMQC toolkit as a free resource for the community to aid with standardized, rapid analysis of QC test images using a cross vendor platform. The toolkit is freely available on the IAEA Human Health Campus (http://bitly.com/IAEA-NMQC), along with further documentation and instructions for its use.

OP-285

Implications of a FDG-PET EARL Protocol for Ga-68 PET Imaging

D. Koopman[1,2], *W. A. Noortman*[1,2], *P. L. Jager*[1], *C. H. Slump*[2], *J. A. van Dalen*[3]; [1]*Isala, Department of Nuclear Medicine, Zwolle, NETHERLANDS,* [2]*MIRA Institute for Biomedical Technology and Technical Medicine, University of Twente, Enschede, NETHERLANDS,* [3]*Isala, Department of Medical Physics, Zwolle, NETHERLANDS.*

Introduction: With the increasing use of Ga-68 PET imaging for neuro-endocrine tumours and prostate cancer, there is or will arise a need for standardization of such Ga-68 based PET scans. We have used settings as prescribed by EARL in standardisation of FDG-PET and tested these for Ga-68 PET imaging. **Methods:** We performed a phantom study using a NEMA Image Quality phantom with sphere diameters 10-37 mm. Spheres were filled with 37 kBq/mL Ga-68 and the background with 3.6 kBq/mL Ga-68. We acquired a 10 min PET scan on a state-of-the-art system (Ingenuity TF, Philips Healthcare). Data were reconstructed using a protocol that fulfils EARL specifications for contrast recovery coefficients (CRCs) using FDG-PET. Mean and maximum CRCs (CRC_{mean} and CRC_{max}) were measured for all phantom spheres. These values were compared to those obtained with Fluor-18 and to EARL specifications for FDG-PET tumour

imaging. **Results:** With Ga-68, we found relatively low CRC_{mean} and CRC_{max} values for all spheres. Values were 2% to 21% lower compared to those obtained with Fluor-18, the highest percentages corresponding to the smallest spheres. CRC_{mean} values for Ga-68 were up to 9% below the lower limit of the EARL specifications. For the small phantom spheres, CRC_{max} values were close to the lower limit, with the CRC_{max} value of the 13 mm sphere 3% below the lower CRC_{max} limit. **Conclusion:** Reconstruction settings for Ga-68 PET should be adapted towards a higher image resolution, to achieve the EARL specifications for FDG-PET. Alternatively, specific EARL accreditation specifications for Ga-68 may be defined for standardization of Ga-68 PET cancer imaging.

OP-286

Robustness of EQ•PET SUV harmonization to tumor-to-background variations

B. S. Spottiswoode[1], M. V. Mattoli[2], M. Milite[3], M. L. Calcagni[2], A. Giordano[2], L. Indovina[4]; [1]Siemens Medical Solutions USA, Inc., Knoxville, TN, UNITED STATES OF AMERICA, [2]Università Cattolica del Sacro Cuore, Rome, ITALY, [3]Siemens Healthcare Srl, Milan, ITALY, [4]Fondazione Policlinico Universitario A. Gemelli, Rome, ITALY.

Introduction: EQ•PET is a reference-based quantification technology that provides clinicians with harmonized SUVs across patient scans, even if acquired on different scanners or reconstructed with different protocols. This is achieved by aligning NEMA phantom recovery curves, either across scanners / protocols or to a standard such as EARL. Alignment involves spatial filter optimization to minimize the difference between recovery curves. Previous work has demonstrated that such an approach is relatively independent of lesion size, clinical classification, location, emission scan duration, and patient BMI (Lasnon et al. EJNMMI 2013). The aim of this work is to assess the dependence of EQ•PET on tumor-to-background variations. **Methods:** A NEMA NU2 phantom with 6 hot spheres was prepared and scanned following the PET EANM guidelines on a Biograph mCT system (Siemens Medical Solutions). Images were reconstructed using point-spread function (PSF) and ordered subset expectation maximization (OSEM3D) methods, both with time of flight. Reconstruction parameters were based on a standard clinical protocol and included a 256×256 matrix, $3.2 \times 3.2 \times 5$ mm^3 voxel dimension, 2 iterations, 21 subsets and a 2 mm Gaussian post filter. An ^{18}F-FDG solution (20.7 kBq/ml) was used to fill spheres. Three different activities were injected into the background to achieve sphere-to-background ratios (SBR) of 10, 5 and 3, respectively. An additional scan was performed without any background (SBR_{inf}). EQ•PET harmonization was performed as described previously based on SUV_{max} measured within each sphere (Kelly, Siemens White Paper, 2014), and using the EARL 2011 reference curves. The optimal EQ•PET filter from the EARL-recommended SBR_{10} was then applied to SBR_3, SBR_5, and SBR_{inf}, and harmonization effectiveness was assessed based on the mean absolute percent difference for all spheres compared to the reference recovery curve. **Results:** The optimal EQ•PET filter in the SBR_{10} scenario reduces the mean ab-

solute percent difference with the EARL reference from 39.4% to 7.1% for PSF, and from 22.0% to 9.6% for OSEM protocols. The same filters applied to the SBR_3, SBR_5 and SBR_{inf} scenarios reduces the mean absolute percent difference from 35.7% to 8.5% for PSF, and from 16.5% to 8.6% for OSEM. **Conclusion:** EQ•PET harmonization produces similar recovery curve alignment for both PSF and OSEM at a range of clinically relevant sphere-to-background ratios. These results suggest that SUV harmonization using EQ•PET is maintained in the presence of varying tumor-to-background ratios.

OP-287

A New ^{64}Cu-Labeled, Metabolic-Resistant Peptide with Nanomolar Affinity for NPY-Y1R for Breast Cancer Targeting

M. Paquette, V. Dumulon-Perreault, S. Ait-Mohand, B. Guérin; Université de Sherbrooke, Sherbrooke, QC, CANADA.

Introduction: Neuropeptide Y1 receptor (NPY-Y1R) is overexpressed in 85% of breast carcinomas, and its presence is modulated in an estrogen-dependent manner, making NPY-Y1R a potential diagnostic target for breast cancer. Recently, ^{68}Ga-labeled [Lys(Pip-Ga-DOTA)^4, Bip^5]BVD15 allowed PET imaging of breast tumors in xenografted mice, despite low *in vitro* plasma stability (Zhang *et al.*, Mol Pharm, 2016). In our group, a series of BVD15 derivatives were tested, but compounds either had excellent stability or low-nanomolar affinity, but not both. In this work, we will present the stability along with the cell binding and uptake of a promising novel ^{64}Cu-labeled peptide with sequence D-Ile-Asn-Hyp-Lys(C6-NOTA)-Tyr-Arg-Cha-Arg-Tyr. **Methods:** Peptide was synthesized on solid phase, conjugated to NOTA chelator and radiolabeled with ^{64}Cu-acetate at pH 7.0 for 30 minutes at room temperature. In vitro stability was assessed by addition of labeled peptide to mouse plasma at 37°C sampled and analysed in a time-dependent manner. Saturation binding curves, time-dependent uptake and inhibition constant (K_i) against the ^{125}I-labeled natural ligand NPY were evaluated in MCF7 cells. Efflux was evaluated by washing and incubating cells with fresh media in a time course after a 1-hour uptake of the tracer. **Results:** Affinity of the compound for NPY-Y1R-expressing MCF7 cells was in the low-nanomolar range, with dissociation constant (K_D) reaching 9.3±3.1 nM and K_i compared to ^{125}I-NPY at 6.6±0.54 nM. Stability studies showed that 41% of the compound is still intact in mouse plasma 3 h after addition, showing a vastly improved performance over previous high-affinity analogs. Optimal uptake was reached at 1h on MCF7 cells, while a significant uptake decrease was observed upon co-application of excess unlabeled peptide between 30 to 240 minutes after tracer addition. Rapid washout from the cells was observed, with only 25% of the 1h uptake remaining 15 minutes after tracer withdrawal. **Conclusion**: The compound D-Ile-Asn-Hyp-Lys(C6-^{64}Cu/NOTA)-

Tyr-Arg-Cha-Arg-Tyr displayed both high *in vivo* stability and receptor-targeting capabilities, but with fast efflux. Further evaluation of the ^{64}Cu-peptide is currently ongoing, and PET imaging of MCF7-bearing mice will soon be carried out.

OP-288

New Radiolabeled Exendin Analogue Shows Increased Renal Clearance

L. Joosten, C. Frielink, M. Gotthardt, M. Brom; Radboud University Medical Center, Nijmegen, NETHERLANDS.

Aim: A promising imaging method for detection of small insulinomas is targeting the glucagon-like peptide-1 (GLP-1) receptor by PET/CT after injection of radiolabeled/^{68}Ga-labeled exendin-4. High accumulation of radiolabeled exendin in the kidneys via tubular reabsorption, can hamper the ability to detect small insulinomas in close proximity of the kidneys. In this study, we developed a novel exendin-analogue with a methionine-isoleucine linker between the chelator (NOTA) and the peptide, aiming at increasing the renal clearance. We examined the renal clearance and insulinoma targeting properties of this new exendin analogue in biodistribution and PET/CT studies in a nude mouse model bearing subcutaneous insulinomas. **Materials and Methods:** NOTA was conjugated via a Met-Ile-linker to the C-terminus of exendin-4 (MI-NOTA-exendin-4). Exendin with NOTA conjugated to a C-terminal lysine was used as a reference. The affinity of the peptides was determined in a competitive binding assay using GLP-1 receptor transfected CHL cells. Biodistribution of ^{68}Ga-NOTA-exendin-4 and ^{68}Ga-MI-NOTA-exendin-4 was performed in INS-1 tumor-bearing BALB/c nude mice to investigate the renal clearance and tumor targeting properties of both peptides and to assess visualization of INS-1 tumors with PET/CT. **Results and Conclusion:** Labeling of NOTA-exendin-4 and MI-NOTA-exendin-4 resulted in a maximum specific activity up to 275 GBq/μmol and 242 GBq/μmol, respectively. The affinity for the GLP-1 receptor was 9.5 nM (95% confidence interval, 7.0 to 12.8 nM) for NOTA-MI-exendin-4 and 4.0 nM (95% confidence interval, 2.5 to 6.2 nM) for NOTA-exendin-4 (p<0.001). *In vivo* biodistribution revealed a significant lower kidney uptake of ^{68}Ga-NOTA-MI-exendin-4 one hour post injection (102.6 ± 14.8 %ID/g), compared to ^{68}Ga-NOTA-exendin-4 (127.2 ± 17.3 %ID/g) (p<0.0001), which was even more pronounced four hours p.i. (34.2 ± 4.2 %ID/g vs 127.7 ± 9.5 %ID/g respectively, p<0.0001). Accumulation of ^{68}Ga-NOTA-MI-exendin-4 in the tumor was 25.0 ± 8.0 four hours p.i. and similar to that of ^{68}Ga-NOTA-exendin-4 (24.9 ± 9.3) (p>0.05). Furthermore, INS-1 tumors were visualized using PET/CT and moreover, the reduced kidney uptake of ^{68}Ga-MI-NOTA-exendin-4 compared to ^{68}Ga-NOTA-exendin-4 was clearly visible. In conclusion, ^{68}Ga-MI-NOTA-exendin-4 showed increased renal clearance of more than 60% four hours p.i. when compared to ^{68}Ga-NOTA-exendin-4, whereas tumor retention did not change significantly. Therefore, ^{68}Ga-labeled MI-NOTA-exendin-4 is a promising improved tracer resulting in better tumor-to-kidney ratios and might allow improved detection of small insulinomas, in close proximity to the kidneys.

OP-289

Metabolic fate of [^{111}In]Sarabesin 3 in mice: Identifying radiometabolites in peripheral blood as well as neutral endopeptidase as the key degrading protease

B. A. Nock[1], E. Lymperis[1], W. Sallegger[2], A. Kaloudi[1], E. P. Krenning[3], M. de Jong[4], T. Maina[5]; [1]Molecular Radiopharmacy, INRASTES, NCSR, Athens, GREECE, [2]PiChem, Graz, AUSTRIA, [3]Department of Nuclear Medicine, Erasmus MC, Rotterdam, NETHERLANDS, [4]Department of Radiology, Erasmus MC, Rotterdam, NETHERLANDS, [5]Molecular Radiopharmacy, INRASTES, NCSR "Demokritos", Athens, GREECE.

Aim: We have previously reported on the GRPR-antagonist Sarabesin 3 (SB3), [DOTA-*p*-aminomethylanilinediglycolate (AMA-DIG)-DPhe[6],Leu-NHEt[13]]BBN(6-13), suitable for labeling with medically relevant radiometals. The PET-radioligand [^{68}Ga]SB3 showed excellent targeting of GRPR-expressing prostate and/or breast cancer lesions in animals and in human. Unexpectedly, the uptake of the respective [^{111}In]SB3 in PC-3 tumors in mice was compromised (8.8±3.0%ID/g *vs*. 34.0±6.9%ID/g for [[67/68]Ga]SB3 at 4 h pi) due to inferior metabolic stability. Tumor values of [^{111}In]SB3 reached comparable to [^{68}Ga]SB3 levels (38.3±7.9%ID/g at 4 h pi) only after coinjection of the neutral endopeptidase (NEP)-inhibitor phosphoramidon (PA). In this study, we were interested to investigate the metabolic patterns of [^{111}In]SB3 in mice and the role of NEP in their formation. For this purpose, we synthesized potential SB3-metabolites and labeled those with [111]In. We subsequently compared their chromatographic behavior *vs*. actual radiometabolite patterns found in peripheral blood after administration of [^{111}In]SB3 in mice applying radio-HPLC. **Materials and Methods**: The potential SB3 metabolites M1: [DOTA-AMA-DIG]DPhe[6],Leu-OH[13]]BBN(6-13), M2: DOTA-AMA-DIG-DPhe-Gln-Trp-Ala-Val-Gly-His-OH, M3: [DOTA-AMA-DIG-DPhe-Gln-Trp-Ala-OH, M4: DOTA-AMA-DIG-DPhe-Gln-Trp-OH and M5: DOTA-AMA-DIG-DPhe-Gln-OH were synthesized on the solid support. SB3 and M1-M5 were labeled with ^{111}In in aqueous acidic (pH 4.6) medium. Each of [^{111}In]SB3 or of the predominant metabolites [^{111}In]M2 and [^{111}In]M4 was injected in the tail vein of mice without or with PA-coinjection. Mouse blood collected at 5 min postinjection (pi) was analyzed by radio-HPLC. Separate HPLC co-injections of authentic [^{111}In] M1-[^{111}In]M5 samples with 5 min blood samples of [^{111}In]SB3, [^{111}In]M2 or [^{111}In]M4 were conducted. **Results**: The major degradation products of [^{111}In]SB3 detected in peripheral mouse blood at 5 min pi were: [^{111}In]M2 (11.3%), [^{111}In]M3 (6.0%), [^{111}In]M4 (5.4%) and [^{111}In]M5 (17.7%) with no evidence of [^{111}In]M1 formation. Treatment of animals with PA resulted in full stabilization of [^{111}In]SB3. Interestingly, [^{111}In]M2 yielded [^{111}In]M3 (9%), [^{111}In]M4 (12%) and [^{111}In]M5 (43.2%) at 5 min pi in mice, but remained intact after PA-coinjection. Radiometabolite [^{111}In]M4 was in vivo stable. **Conclusions**: In agreement to previous findings, this study has confirmed the crucial role of NEP in the bioavailability of the GRPR-antagonist [^{111}In]SB3 which is of great significance for tumor uptake. Notably, the *des*-Leu[13] radiometabolite [^{111}In]M2 was also susceptible to NEP, leading to the same degradation products.

OP-290

New radiolabelled minigastrin analogues with improved CCK2R targeting for diagnostic and therapeutic use

M. Klingler[1], C. Rangger[1], D. Summer[1], J. Foster[2], J. K. Sosabowski[2], E. von Guggenberg[1]; [1]Medical University of Innsbruck, Innsbruck, AUSTRIA, [2]Barts and the London School of Medicine, London, UNITED KINGDOM.

Introduction: Medullary thyroid carcinoma and other cholecystokinin-2 receptor (CCK2R) expressing tumours can be targeted by radiolabelled minigastrin (MG) analogues showing high affinity to this receptor. We have designed four new DOTA-conjugated MG analogues aiming to increase biological stability and tumour-to-organ ratios when compared to native MG and other previously developed MG analogues. **Methods:** Based on MG11 (LAYGW-MDF-NH$_2$) four new DOTA-conjugated MG analogues with specific amino acid substitutions on position 6 and 8 were synthesized (DOTA-MGS1-4). Receptor affinity and cell uptake were tested using CCK2R-positive AR42J rat pancreatic acinar tumour cells and A431 human epidermoid carcinoma cells transfected with human CCK2R and mock-transfected cells. *In vitro* stability analyses where carried out in human serum (up to 24 h p.i.), rat liver and kidney homogenates (up to 2 h p.i.). With the two analogues showing the highest receptor affinity and cell uptake *in vivo* stability tests (10 min p.i.), dual modality single photon emission computer tomography (SPECT-CT) images and subsequent biodistribution analysis where carried out in normal or tumour bearing mice. **Results**: ^{111}In-DOTA-MGS1 and ^{111}In-DOTA-MGS4 showed high receptor affinity (IC50 <6 nM) and high receptor-specific cell uptake (~10 % in AR42J and ~20 % in A431-CCK2R) whereas ^{111}In-DOTA-MGS2 and ^{111}In-DOTA-MGS3 showed much lower affinity (IC50 >40 nM) and uptake values (<5 % in AR42J and <4 % in A431-CCK2R). ^{111}In-DOTA-MGS3 and ^{111}In-DOTA-MGS4 showed higher resistance against enzymatic degradation *in vitro* with >93 % intact radioliand in serum, and >11 % in rat tissue homogenates than ^{111}In-DOTA-MGS1 and ^{111}In-DOTA-MGS2 (serum <60 %, rat tissue homogenates <1 %). Concerning the i*n vivo* stability no intact radiopeptide was detectable for ^{111}In-DOTA-MGS1, whereas ^{111}In-DOTA-MGS4 showed a very high *in vivo* stability (>75 % in blood and liver, >24 % in kidney and urine). With both radiopeptides tumour xenografts could be clearly visualised on SPECT/CT images. ^{111}In-DOTA-MGS4 showed a high tumour uptake (10.2±2.0 % ID/g) and a favourable tumour-to-kidney ratio (2.6±0.9 % ID/g), whereas ^{111}In-DOTA-MGS1 displayed only a tumour uptake of 1.3±0.1 % ID/g and a tumour-to-kidney ratio of 1.2±0.1 % ID/g. **Conclusions:** The *in vitro* and *in vivo* characterization of the new four MG analogues developed confirmed the possibility of introducing stabilizing amino acid substitutions in the carboxy-terminal part of the peptide sequence without impairing CCK2R affinity. Alternative substitutions are currently under investigation to further optimize this approach.

OP-291

Application of SSTR radioligands in Breast Cancer

S. U. Dalm, G. N. Doeswijk, J. C. Haeck, A. M. Sieuwerts, J. W. M. Martens, C. H. M. van Deurzen, M. de Jong; Erasmus MC, Rotterdam, NETHERLANDS.

Background: Somatostatin receptor (SSTR) radioligands are successfully applied for imaging and treatment of neuroendocrine tumors. For breast cancer (BC), earlier the use of SSTR radioligands was not as successful as anticipated. These studies, performed over a decade ago, had varying results and indicated low and heterogeneous SSTR expression in BC as main limiting factors. Apart from SSTR expression, the majority of these studies did not discriminate between different BC subtypes. Furthermore, compared to the current state-of-the-art, imaging devices and radioligands used were suboptimal. The aim of our studies was to investigate once again the potential of SSTR radioligands for BC targeting, taking into account important BC characteristics and recent improvements with respect to radioligands. **Materials and Methods:** *SSTR2* mRNA expression of 915 BCs was determined and associated with BC characteristics. Also, tissues from primary BCs and corresponding metastases (n=60 pairs) were analyzed and *SSTR2* mRNA expression was compared. Furthermore, autoradiography studies using ^{111}In-octreotate were performed on 51 BC specimens to analyze SSTR protein expression. Finally, in response to the reported low and heterogeneous SSTR expression, we compared the use of a radiolabeled SSTR antagonist vs an agonist for BC targeting. SSTR antagonists have shown to be superior to SSTR agonists for targeting of neuroendocrine tumors. In vitro autoradiography studies (n=40 BCs) and in vivo SPECT/MRI studies in an estrogen receptor (ER)-positive BC mouse model (T126, n=6 per group) comparing radiolabeled DOTA-JR11, an SSTR antagonist, and radiolabeled DOTA-Tyr[3]-octreotate, an SSTR agonist, were performed. **Results:** *SSTR2* mRNA expression showed a significant correlation with ER-positivity of BCs (p<0.001). Furthermore, in the majority of cases *SSTR2* mRNA expression of primary BC and corresponding metastases (both regional and distant metastases) was equivalent. In the autoradiography studies, we found 44/51 tumors to be SSTR-positive of which 25% showed homogenous expression. In vitro binding and in vivo tumor uptake of radiolabeled DOTA-JR11 was significantly higher than that of radiolabeled DOTA-Tyr[3]-octreotate. The median (min-max) ratio antagonist/agonist binding in vitro was 3.39 (2-5). SPECT/MRI studies resulted in a tumor uptake of 1.12±0.4 and 0.8±0.1 %ID/mL (p<0.05) for the antagonist and agonist, respectively. **Conclusion:** Our findings suggest the use of SSTR radioligands for BC imaging, and perhaps also therapy, should be reconsidered. ER-positive BC patients can potentially benefit most from the application of SSTR radioligands in both primary and metastatic disease. Our results also indicate that radiolabeled SSTR antagonists are superior to radiolabeled SSTR agonists for BC targeting.

Radionuclide tumor targeting using ADAPT scaffold proteins: aspects of label positioning and residualizing properties of the label

J. Garousi[1], S. Lindbo[2], B. Mitran[3], M. Altai[1], J. Buijs[4], A. Orlova[3], S. Hober[2], V. Tolmachev[1]; [1]Institute for Immunology, Genetics and Pathology, Uppsala University, Uppsala, SWEDEN, [2]School of Biotechnology, Division of Protein Technology, KTH Royal Institute of Technology, Stockholm, SWEDEN, [3]Division of Molecular Imaging,

Department of Medicinal Chemistry, Uppsala University, Uppsala, SWEDEN, [4]Uppsala University, Uppsala, SWEDEN.

Aim: ADAPTs are small-size (5 kDa) affinity proteins, derived from the albumin-binding domain (ABD) of streptococcal protein G. Previous studies have demonstrated the feasibility of high-contrast imaging of HER2-expressing xenografts in mice using anti-HER2 ADAPT6 site-specifically labeled at N-terminus with ^{111}In and ^{68}Ga within 1-4 h pi. Further studies identified the variant (HE)$_3$DANS-ADAPT6 as providing the best tumor-to-organ rations when labelled at N-terminus with ^{111}In using DOTA. The aim of this study is to determine if positioning of radiometal (^{111}In) and radiohalogen (^{125}I) labels at different ends of the molecule (C- vs N-termini) could affect the biodistribution. **Materials and Methods:** Two variants of (HE)$_3$DANS-ADAPT6 protein having cysteine at C-terminus (Cys[59]-ADAPT6) and N-terminus (Cys[2]-ADAPT6) were produced and labeled with ^{111}In using maleimido-DOTA or ^{125}I using ((4-hydroxyphenyl)ethyl)maleimide (HPEM). The tracers were evaluated *in vitro* and *in vivo*. BALB/C nu/nu mice bearing SKOV3 xenografts were used as a model to study biodistribution. **Results**: *In vitro* and *in vivo* data confirmed HER2-mediated binding of all four tracers to HER2-expressing cells. Internalization of conjugates by both SKOV-3 and BT-474 cells was slow. Surprisingly, the uptake in SKOV3 xenografts of radioiodinated conjugates was significantly higher than uptake of radiometal-labeled counterparts. At 4 h pi, the tumor uptake was 15±2, 22±3, 10.6±0.5, and 11.8±0.5 % ID/g for ^{111}In-DOTA-Cys[59]-ADAPT6, ^{125}I-HPEM-Cys[59]-ADAPT6, ^{111}In-DOTA-Cys[2]-ADAPT6, and ^{125}I-HPEM-Cys[2]-ADAPT6 respectively. Tumor-to-blood ratios were 277±35, 53±10, 254±37 and 61±14, respectively, at this time point. We have found that renal retention of the radioiodinated variants (renal uptake of 1.7±0.3 ID/g at 4 h p.i., regardless of position) was ca.150-lower compared to ^{111}In-labeled variants. However, the uptake in other organs was higher for radioiodine, most likely due to release of radiometabolites from kidneys into blood. Therefore, tumor-to-organ ratios (excluding kidneys) were higher for ^{111}In-DOTA labeled tracers. Overall, ^{111}In-DOTA-Cys[59]-ADAPT6 provided significantly higher tumor-to-lung, tumor-to-liver, tumor-to-spleen and tumor-to-muscle ratios compared to ^{111}In-DOTA-Cys[2]-ADAPT6. Tumor-to-organ ratios were similar for ^{125}I-HPEM-Cys[59]-ADAPT6 and ^{125}I-HPEM-Cys[2]-ADAPT6, but ^{125}I-HPEM-Cys[59]-ADAPT6 has twice higher tumor uptake and provided twice higher tumor-to-kidney ratio. **Conclusion:** Both character and position of labels had substantial influence on imaging properties of ADAPT6. Non-residualizing radiohalogen labels decreased renal uptake dramatically. An optimal position for both ^{125}I-HPEM and ^{111}In-DOTA labels is at C-terminus.

OP-293

Effectivity of a combined treatment with the m-TOR inhibitor RAD001 and Peptide Receptor Radionuclide therapy with Lu-177 DOTA TATE evaluated with Ga-68 DOTA TATE PET in a tumor model of the mouse

J. Zellmer[1], L. Vomacka[1], G. Böning[1], F. J. Gildehaus[1], J. Carlsen[1], E. Mille[1], M. Hacker[2], P. Bartenstein[1], A. R. Haug[2], **H. Ilhan[1]**;

[1]*Department of Nuclear Medicine, University Hospital of Munich, Munich, GERMANY,* [2]*Division of Nuclear Medicine, Department of Biomedical Imaging and Image Guided Therapy, Medical University of Vienna, Vienna, AUSTRIA.*

Purpose: To evaluate the efficacy of a combined treatment with the m-TOR inhibitor RAD001 (Everolimus) and Peptide Receptor Radionuclide Therapy (PRRT) with Lu-177 DOTA TATE in a somatostatin-receptor (SSTR) positive tumor model of the mouse. **Methods:** Athymic CD1-mice (10 weeks) were divided into 4 groups (Gr.) and injected with the SSTR-positive AR42J tumor cell line at day 0. A baseline Ga-68 DOTA TATE PET scan was performed 5 days after tumor injection. Therapy was started following PET at day 5. Gr. 1 (n=7) was treated with Placebo, Gr. 2 (n=8) with 5 mg/kg RAD001 weekly, Gr. 3 (n=7) with a single PRRT cycle (80 MBq Lu-177 DOTA TATE) and Gr. 4 (n=8) with a combination of RAD-001 and PRRT. Follow-up PET was performed 1, 2 and 4 weeks after start of therapy. The tumor volume was assessed manually (MTV) and threshold based in PET (biological tumor volume, BTV). PET was used to quantify the tumor to reference ratio (TRR; maximum uptake in the tumor divided by mean uptake in muscle as reference). Numbers are given as mean ±SEM. **Results:** Animals treated with Placebo and RAD001 monotherapy were euthanized according to the requirements of the local animal ethics committee at week 2 due to excessive tumor growth. One mouse of Gr. 4 died due to aspiration during application of RAD001 at day 26. All other animals of Gr. 3 and 4 were euthanized after the last PET scan 4 weeks after treatment. Tumor volume at week 2 was significantly higher in Gr. 1 compared to all other groups. Gr. 2 presented higher MTV compared to the PRRT groups (Gr. 1: 1594,4 mm^3 ±779,0; Gr. 2: 394 mm^3 ±80,0; Gr. 3: 26,0 mm^3 ±14,8; Gr. 4: 36,2 ±14,0). There was a high correlation of MTV and BTV (r^2=0,9). Mean TRR in Ga-68 DOTA TATE PET at week 2 was significantly lower in Gr. 1 and 2 compared to Gr. 3 and 4 (Gr. 1: 5,9 ±1,5; Gr. 2: 6,9 ±1,2; Gr. 3: 1,4 ±0,18; Gr. 4: 1,18 ±0,5). Mean TRR in Gr. 3 and 4 increased until week 4 and was not significantly different (Gr. 3: 4,96 ±2,18; Gr. 4: 11,17 ±3,93). **Conclusion:** Treatment with Lu-177 DOTA TATE is highly effective in AR42J tumor bearing mice. The combination of PRRT and RAD001 is equally effective and results in significantly smaller tumor-growth compared to monotherapy with RAD001 alone or Placebo.

OP-294

The Receptor UT of Urotensin-II is a New Target for Imaging Solid Tumor with Radiolabeled DOTA-Peptide Ligands

B. Poret[1,2], *L. Desrue[2], N. Perzo[2], P. M. Coly[2], J. E. Joubert[2], M. A. Bonin[3], R. Leduc[3], R. Modzelewski[1], F. Morin[2], H. Castel[2], P. Vera[1], P. Bohn[1], P. Gandolfo[2];* [1]*EA 4108, Laboratory of Computer Science, Information Processing and Systems (LITIS), team "QuantIF", Centre Henri Becquerel, Rouen, FRANCE,* [2]*Normandie Univ, UNIROUEN, INSERM 1239, DC2N, Laboratory of Neuronal and Neuroendocrine Differentiation and Communication, Mont-Saint-Aignan, FRANCE,* [3]*Department of Physiology & Pharmacology, Institute of Sherbrooke, Faculty of Medicine and Health Sciences, Sherbrooke University – Health Campus, Sherbrooke, QC, CANADA.*

Overexpression of G protein-coupled receptors (GPCRs) in tumor has been exploited to develop GPCR-targeting radioligands used *in vivo* for imaging solid tumors in cancer. In particular, somatostatin analogs labeled with [111]Indium (^{111}In-OctreoScan) are used for the diagnostic of neuroendocrine tumors. The vasoactive neuropeptide urotensin-II (UII), which shares structural analogies with somatostatin, interacts with a single high affinity GPCR named UT. We previously established that UII exhibits potent chemotactic properties to promote cell migration and angiogenesis in glioblastomas. High expression of UT in human solid tumors including lung, colorectal, prostate or breast carcinomas, suggests that UT constitutes an interesting target to design radiolabeled UII analogs for diagnostic or therapeutic approaches. In a first step, two urotensinergic ligands (UII and a biased analog of UT, urantide) containing the chelating group DOTA, able to bind radioactive isotopes, have been successfully synthetized. A radiolabeling protocol of DOTA-UII and DOTA-urantide with [111]Indium was first validated. When incubated for 3h period in human plasma, only 30% of the radioligand showed degradation. Graded concentrations of both DOTA-UII and DOTA-urantide induced a dose-dependent increase in cytosolic calcium concentration in HEK293 cells expressing UT, with similar potency and efficacy to that obtained with UII (EC_{50}: 1.26 10^{-8} M and 2.09 10^{-8} M, UII and DOTA-UII, respectively) and urantide (EC_{50}: 1.82 10^{-8} M and 1.52 10^{-8} M, urantide and DOTA-urantide, respectively). DOTA-UII was also able to promote UT internalization (ELISA and immunocytochemistry) in HEK293 cells expressing UT, whereas DOTA-urantide was ineffective, together suggesting that DOTA analogs kept ability to bind and activate human UT. To characterize the best cell line for imaging with DOTA-UII radionuclide, we have first characterized a series of human tumoral cell lines. Among 12 cell lines tested from brain, breast, lung, colorectal and prostate, 9 of them exhibited a strong expression of UT. Moreover, a treatment with UII stimulated cell proliferation (7/12) and/or cell migration (5/12). The more responsive cell lines are currently tested *in vivo* in xenografted mice. To control first the biodistribution of ^{111}In-DOTA-UII, we performed injection in C57Bl/6J mice (mUTS2R[+/+], mUTS2R[-/-], or hUTS2R[+/+]). We observed a slight signal of ^{111}In-DOTA-UII restricted in kidney in all animals and a very fast clearance in the three groups, indicating a weak binding of UT in physiological conditions. The weak expression of UT in physiology and the strong expression of UT in solid tumors suggest that radionuclide DOTA-UII exhibits very interesting properties for the diagnosis and/or therapy.

Combined imaging in cervical cancer with hybrid FDG-PET/MRI for primary staging followed by Tc-99m-SPECT/CT for pre-surgical sentinel lymph node mapping

S. Sahbai[1], F. Fiz[1], F. Taran[2], S. Brucker[2], D. Wallwiener[2], A. Staebler[3], H. Dittmann[1], C. la Fougère[1]; [1]Nuclear Medicine, Tübingen, GERMANY, [2]Gynecology and Obstetrics, Tübingen, GERMANY, [3]Pathology, Tübingen, GERMANY.

Introduction: F-18-FDG-PET/MRI for primary staging in patients with cervical cancer is considered to have a high potential for initial staging and may provide prognostic information, since the presence of metastatic lymph nodes (LN) is an important prognostic factor. Currently, the use of pre-surgical sentinel lymph node (SLN) mapping in early-stage tumor is preferred and could reduce post-surgical morbidity. The aim of our study was to investigate the pre-surgical use of PET/MRI and SLN mapping combined with SPECT/CT for the detection of LN-metastases. **Methods:** Histologically proven cervical cancer patients were prospectively included and underwent initially a whole-body F-18-FDG-PET/MRI (Siemens Biograph mMR®). SLN mapping succeeded one day before surgery after peri-cervical injection of Tc-99m-nanocolloid with SPECT/CT (GE Healthcare Discovery NM 670 Pro®). Surgical SLN biopsy was performed with gamma hand probe. Pre-operative imaging results were compared to histological findings (primary tumor, location, SLNs and non SLNs). **Results:** So far, eight patients were included in this prospective study. PET/MRI was capable to detect all 8 primary tumor lesions of the uterine cervix and all 4 involved LN regions in the 2 patients with LN metastases. One patient with apparent clinical early-stage but advanced metastatic disease in PET/MRI did not receive SLN mapping and surgery. In the 7 remaining patients, SLN detection rate in pre-operative SPECT/CT was 100% and 79% based on patient and on hemi-pelvis analysis respectively. The false negative rate of metastatic LN detection was 7% (1/14) based on hemi-pelvis analysis according to SPECT/CT; this was reduced to 0% by adding PET/MRI results. **Conclusion:** The use of pre-operative PET/MRI and SLN mapping with SPECT/CT in cervical cancer could provide prognostic information prior to surgery. This combined dual-time-point imaging may avoid unnecessary systematic bilateral lymphadenectomy and additional morbidity by increasing the accuracy of LN metastases detection.

OP-299

Utility of multiparametric PET/MRI for response assessment of radiochemotherapy or neoadjuvant chemotherapy in cervical cancer patients

T. Sarabhai, Y. Erfanian, M. Forsting, K. Herrmann, L. Umutlu, J. Grueneisen; University Hospital Essen, Essen, GERMANY.

Purpose: The aim of the study was to investigate the diagnostic potential of simultaneous multiparametric PET/MRI for therapy response assessment of radiochemotherapy or neoadjuvant chemotherapy in patients with primary cervical cancer. **Subjects & Methods:** The patient cohort comprised 9 patients with a histopathologically confirmed primary cancer of the uterine cervix. All patients were prospectively enrolled for a two examination approach of simultaneous 18F-FDG PET/MR imaging: 1. prior to the start and 2. after completion of definitive radiochemotherapy.(n = 3) or neoadjuvant chemotherapy (n = 6). Therapy response was assessed based on RECIST 1.1 and PERCIST 1.0 criteria. In addition, several 18F-FDG PET- and MRI-derived metabolic (18F-FDG PET: SUVs), functional (DWI: ADC values, DCE-MRI: Ktrans, Kep, Ve, iAUC) and morphological (tumor size) parameters were determined. Histopathological verification due to biopsy or subsequent tumor resection served as the reference standard. **Results:** Simultaneous multiparametric PET/MRI has been successfully completed in all 9 patients. In accordance with the RECIST- and PERCIST-criteria, partial response (PR) or complete response (CR) could be determined in 7 patients (RECIST: CR = 1, PR = 6; PERCIST: CR = 2; PR = 5). The two remaining patients showed progressive or stable disease. Multiparametric PET/MR analysis of therapy responders revealed reduction of the mean tumor size (55mm to 20mm), perfusion parameters (Ktrans: 0.42 to 0.28, iAUC: 10.45 to 4.69), metabolic activity (SUVmax: 16.5 to 5.9; SUVmean: 7.8 to 3.5) and an increase of ADC values (ADCmean: 763 to 1032; ADCmin: 381 to 667). On the other hand, in patients with PR and CR tumor size and ADC-values remained stable, while an increase of perfusion parameters (Ktrans: 0.33 to 0.69:, Ve: 0.32 to 0.61, iAUC: 9.09 to 22.72) and metabolic activity (SUVmax 14.6 to 17.3; SUVmean: 6.7 to 7.8) was evident after treatment. **Conclusion:** In addition to commonly applied response criteria (RECIST, PERCIST), integrated PET/MRI provides certain quantitative parameters, reflecting underlying tumorbiological features, which might enable a more comprehensive treatment response assessment of radiochemotherapy and neoadjuvant chemotherapy in cervical cancer patients.

OP-300

Preoperative staging of endometrial cancer: prognostic role of PET-derived parameters

P. Mapelli[1], E. Incerti[1], A. Bergamini[2], F. Fallanca[1], P. M. V. Rancoita[3], R. Cioffi[2], M. Petrone[2], E. Rabaiotti[2], G. Mangili[2], L. Gianolli[1], M. Picchio[1]; [1]Nuclear Medicine Department, IRCCS San Raffaele Scientific Institute, Milano, ITALY, [2]Obstetrics and Gynecology, IRCCS San Raffaele Scientific Institute, Milano, ITALY, [3]University Centre of Statistics in the Biomedical Sciences, Vita-Salute San Raffaele University, Milano, ITALY.

Purpose: To investigate the preoperative prognostic role of FDG PET/CT in patients with endometrial carcinoma (EC). **Subjects & Methods:** 18F-FDG PET/CT was performed in 57 patients for EC preoperative staging (August 2009 - July 2016). Maximum and mean standardized uptake values (SUVmax, mean), metabolic tumour volume (MTV) and total lesion glycolysis (TLG) of primary tumours, at different thresholds of 40%, 50%, 60% (40-50-60), were evaluated and compared with anatomopathological features. The diagnostic performance of PET-parameters in discriminating low and high-risk disease (pT1 vs pT2-pT3-pT4 , or International Federation of Gynecology and Obstetrics - FIGO Stage I vs II-III-IV, or endometrioid vs other histotype) was evaluated with the Receiver Operating Characteristics (ROC) curve and logistic regression. Cox regression analysis and logrank test were used to assess the association with overall survival (OS) and recurrence-free survival (RFS). **Results:** Mean age at time of PET/CT was 64 years, range: 24-83 years. Categorized TLG40-50-60 with their optimal cut-off were the only parameters related to FIGO stage I versus II-III-IV (P=0.0035 for all). The cut-offs for risk stratification were 83.69, 61.81 and 41.32, respectively, with corresponding sensitivity and specificity of 60.00% and 71.43% for all parameters. TNM stage (pT2, pT3, pT4 vs pT1) was significantly predicted only by the TLG40-50 categorized with their optimal cut-off (P=0.0344 and 0.0211, respectively). The optimal thresholds were 99.55 and 77.58, respectively, with sensitivity of 50.00% for both parameters and specificity of 81.4% and 83.72%, respectively. Categorized SUVmax and SUVmean40-50-60 with the optimal cut-off (14.35, 8.55, 9.8 and 10.9, respectively) were the only parameters that significantly discriminated between endometrioid vs non endometrioid subtype (P=0.0145 for SUVmax and SUVmean50-60, P=0.0237 for SUVmean40). Corresponding sensitivity was 64.86% and 62.16% for SUVmax and SUVmean50-60 and 62.16% for SUVmean40; specificity was 70.00% for all parameters. The mean OS (mean ±SD) was 79.77% ±3.34 and the mean RFS rate was 77.89±3.73. Tumour type was the only variable significantly associated with OS (P=0.0486). The categorized TLG50 was the only variable significantly associated with RFS (P=0.0472): specifically, TLG50>77.58 cc is associated with a higher risk of relapse. **Conclusion:** TLG40-50-60 of primary EC can predict FIGO staging; TLG40-50 can predict pathological staging. These parameters, being able to discriminating between low and high risk disease, may help the preoperative prediction of EC aggressiveness.

OP-301

Prognostic value of 18F-FDG PET/CT in restaging of locally advanced cervical cancer after concomitant chemoradiation therapy

G. M. Lima, A. Matti, E. De Crescenzo, G. Polverari, A. M. Perrone, P. De Iaco, C. Nanni, S. Fanti; S.Orsola-Malpighi University Hospital, Bologna, ITALY.

Aim: The aim was to investigate the prognostic value of 18F-FDG PET/CT, in terms of overall survival (OS), in restaging of locally advanced cervical cancer (LACC) treated with concomitant chemo-radiation therapy (CCRT). We evaluated the prognostic value

of both intensity- and volume-based PET parameters (SUVmax, SUVmean, MTV and TLG). **Methods:** 78 patients (age 35-94, median 66.3) affected by locally-advanced cervical cancer (LACC, stage IB - IVA) and treated with concomitant chemo-radiation therapy (CCRT) were retrospectively enrolled. For each patient, a full clinical history, including histology, treatment (CCRT +/- boost + brachytherapy), and follow up (median 42.2 months) were available. Each patient underwent a 18F-FDG PET/CT scan both in staging (PET1) and restaging at least three months after the end of treatment (PET2). All PET/CT scans were revised by two expert nuclear medicine physicians. Post-treatment scans were classified into 4 groups according to EORTC criteria: complete metabolic response (CMR), partial metabolic response (PMR), stable metabolic disease (SMD), progressive metabolic disease (PMD). We also classified post-treatment scans on the base of percentage variation of SUVmean, MTV and TLG (CMR: no significant uptake, PMR: SUVmean/MTV/TLG reduction >25%, SUVmean/MTV/TLG increase <25% and decrease<25%, PMD: SUVmean/MTV/TLG increase >25%). The intergroups cut-offs were derived from EORTC criteria. A survival Kaplan-Meier analysis was performed to verify the prognostic significance of the PET2 response. **Results:** Among 78 patients there were 61 squamous cell carcinoma, 14 adenocarcinoma, 3 others types). In this cohort of patients, the statistical analysis with the Kaplan-Meier method showed a highly statistically significant difference in OS between patients with a CMR compared to patient with a PMR, SDM and PMD. The same statistically significant results were obtained employing SUVmax (p=0,0001), SUVmean (p<0,0001), MTV (p<0,0001) and TLG (p<0,0001) as PET evaluation parameter. The optimal OS difference was observed in CMR group vs non-complete metabolic response group (PMR, SMD, PMD). **Discussion and Conclusion:** A complete metabolic response in post-treatment 18F-FDG PET/CT scan, evaluated through SUVmax, SUVmean, MTV and TLG, predicted a lower risk of death in patients with LACC treated with CCRT. Patients with a non-complete PET/CT response after chemo-radiation therapy showed a lower OS and they may benefit from more aggressive treatment. Both intensity- and volume-based PET parameters showed a high prognostic value, in terms of OS, in our cohort of patients. Further studies including a larger number of patients prospectively enrolled are needed to confirm our preliminary findings.

OP-302

Combined FDG and 4FMFES PET Imaging in ER+ Breast Cancer Patients for Improved Diagnostic and Prognostic Value

M. Paquette, É. Lavallée, S. Phoenix, H. Senta, B. Guérin, J. E. van Lier, R. Lecomte, É. E. Turcotte; Université de Sherbrooke, Sherbrooke, QC, CANADA.

Introduction: FDG-PET is widely used for detection and treatment follow-up of breast cancer. However, FDG performs relatively poorly for luminal subtypes, which constitutes the vast majority of breast cancers. On the other hand, most luminal tumors express high levels of estrogen receptors (ER). An ongoing phase II clinical trial evaluating the novel ER PET tracer 4FMFES in ER+ breast cancer patients showed substantial gain in tumor contrast and detection rate over the widely-studied FES, with no identified drawbacks. The study focusses now on the complementary information that FDG-PET and 4FMFES-PET could provide to clinicians in order to enhance diagnostic confidence and prognostic value. **Subjects & Methods:** The preliminary, ongoing analysis includes so far 13 ER+ breast cancer patients. Each patient underwent whole-body PET/CT scans 1 hour following administration of either 186±25 MBq 4FMFES or 182±24 MBq FDG at least 48 h apart and within a maximum 2-week interval. Tumor uptake for each tracer was reported as SUV_{Max} values, and background proximal to each lesion reported as SUV_{Mean}. Except for one patient, hormone therapy was withdrawn at least 6 weeks prior to 4FMFES imaging. **Results:** A total of 78 lesions were detected using 4FMFES, whereas FDG only distinguished 66 foci**.** Twelve tumors were FDG+ and 4FMFES-, and 22 were only detected using 4FMFES. One patient was under tamoxifen therapy during the imaging protocol, and was the only patient negative to 4FMFES, likely as a result of pharmacological competition. Of note was one patient negative on FDG-PET, but positive with an extensive metastatic disease using 4FMFES. In two other patients, 4FMFES allowed restaging by detection of distant bone metastases unseen using FDG. Inversely, two liver metastases and an intestinal neoplasia were only seen using FDG in 3 other cases. Overall FDG tumor uptake was significantly higher (p < 0.001) than 4FMFES, with SUV_{Max} of 5.4 ± 3.8 and 2.7 ± 1.9, respectively. Background signal was in average significantly lower with 4FMFES (SUV_{Mean} 0.36 ± 0.09) than with FDG (SUV_{Mean} = 0.90 ± 0.43; p < 0.001). As a result, a clear trend toward better tumor-to-background ratio using 4FMFES compared to FDG was observed. **Conclusion:** While FDG PET is a well-established procedure for breast cancer detection and therapy follow-up, complementation with 4FMFES PET could further improve diagnosis and refine staging. High tumor contrast using 4FMFES could confer an advantage over FDG for small, hypometabolic ER+ lesions.

OP-303

Qualitative and quantitative analyses of ¹⁸F-FES and ¹⁸F-FDHT uptake in patients with metastatic breast cancer: an interobserver variability study

*L. H. Mammatas[1], C. M. Venema[2], C. P. Schröder[2], M. van Kruchten[2], G. Apollonio[2], A. W. J. M. Glaudemans[3], A. H. H. Bongaerts[3], O. S. Hoekstra[4], H. M. W. Verheul[1], E. Menke-van der Houven van Oordt[1]; [1]Department of Medical Oncology, VUmc Cancer Center Amsterdam, VU University Medical Center, Amsterdam, NETHERLANDS, [2]Department of Medical Oncology, University of Groningen, University Medical Center Groningen, Groningen, NETHERLANDS, [3]Department of Nuclear Medicine and Molecular Imaging, University of Groningen, University Medical Center Groningen, Groningen, NETHERLANDS, [4]Department of Radiology and Nuclear Medicine VU University Medical Center, Amsterdam, NETHERLANDS, [5]Department of Pathology & Medical Biology, University of Groningen, University Medical Center Groningen, Groningen, NETHERLANDS.

Aim: While estrogen deprivation is a cornerstone of treatment in patients with estrogen receptor (ER) positive breast cancer, androgen receptor (AR) blockade is currently under investigation. In a recent pilot study, we showed that ^{18}F-fluoroestradiol (^{18}F-FES) and ^{18}F-fluorodihydrotestosterone (^{18}F-FDHT) uptake in breast cancer lesions correlates well with, respectively, ER (sensitivity and specificity 100%) and AR (sensitivity 91%, specificity 100%) expression in biopsies. A SUV_{max} >1.9 was identified as the optimal threshold for AR-positive tumors (>10% staining), and a SUV_{max} >1.5 for ER-positive tumors (>1% staining). These techniques have the ability to visualize receptor status in all lesions of a patient, which may guide treatment decisions. Here, we examined interobserver differences, since high agreement is required for use as clinical imaging biomarkers. **Materials and Methods:** In this prospective two-center study, 2 independent observers qualitatively and quantitatively scored all lesions visible on bone scan and high-resolution CT (>1cm) on both ^{18}F-FES and ^{18}F-FDHT PET/CT in patients with ER-positive metastatic breast cancer. ^{18}F-FES and ^{18}F-FDHT PET/CT were performed ≤14 days of each other and bone scan and high-resolution CT were performed <6 weeks of the PET scans. A visually PET-positive lesion was defined as uptake above background in surrounding tissue of the same origin. Observers 1 and 2 used manual and semi-automated delineation methods, respectively. Interobserver agreement was determined by an intraclass correlation coefficient (ICC) with a 95% confidence interval (95% CI). **Results:** Ten patients were evaluated and observers 1 and 2, respectively, identified 64 and 69 positive lesions on ^{18}F-FES PET and 36 and 37 positive lesions on ^{18}F-FDHT PET. On CT and bone scan, respectively, 6 and 11 additional lesions were seen, while 55 and 33 PET-positive lesions were not identified. Comparison of qualitative and quantitative results showed a SUV_{max} >1.5 in 44% and 39% of the lesions scored visually negative on ^{18}F-FES PET by observers 1 and 2, respectively. For ^{18}F-FDHT PET, 31% and 52% of the visually negative lesions had a SUV_{max} >1.9 suggesting the importance of quantification. Interobserver agreement was excellent for ^{18}F-FES SUV_{max} (ICC 0.98, 95% CI 0.96-0.98) and good for ^{18}F-FDHT SUV_{max} (ICC 0.78, 95% CI 0.66-0.85). SUV_{max} showed a higher, although not significantly different, level of concordance compared to SUV_{peak} and SUV_{mean} with isocontour 70% of maximum. **Conclusion:** Quantification of ^{18}F-FES and ^{18}F-FDHT uptake in breast cancer lesions using SUV_{max} shows high consistency between observers, supporting use in clinical practice.

^{68}Ga-NOTA-BBN-RGD PET/CT for GRPR and Integrin αvβ3 Imaging in Patients with Breast Cancer

J. Zhang[1,2], *F. Mao*[3], *G. Niu*[2], *L. Peng*[3], *L. Lang*[2], *F. Li*[1], *H. Ying*[4], *H. Wu*[5], *B. Pan*[5], *Z. Zhu*[1], *X. Chen*[2]; *[1]Department of Nuclear Medicine, Peking Union Medical College Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, CHINA, [2]Laboratory of Molecular Imaging and Nanomedicine (LOMIN), National Institute of Biomedical Imaging and Bioengineering (NIBIB), National Institutes of Health (NIH), Bethesda, MD, UNITED STATES OF AMERICA, [3]Department of Breast Surgery, Peking Union Medical College Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, CHINA, [4]Department of Medical Oncology, Peking Union Medical College Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, CHINA, [5]Department of Pathology, Peking Union Medical College Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, CHINA.*

Purpose: This study was designed to assess a novel GRPR and integrin αvβ3 dual targeting positron emission tomography/computed tomography (PET/CT) using ^{68}Ga-NOTA-BBN-RGD in patients with breast cancer and metastasis. **Methods:** Twenty-two patients (29-62 y, mean age 52.5±9.3 y) were recruited either with suspected breast cancer on screening mammography (n=16) or underwent breast cancer radical mastectomy (n=6). All the 22 patients underwent PET/CT at 30-45 min after intravenous injection of 1.85 MBq per kilogram of body weight of ^{68}Ga-NOTA-BBN-RGD. 11 of 22 patients also accepted ^{68}Ga-NOTA-BBN PET/CT within 2 weeks for comparison. A final diagnosis was made based on the histopathologic examination of surgical excision or biopsy. Immunohistochemical staining of tumor samples against GRPR and integrin αvβ3 was performed and correlated with ^{68}Ga-NOTA-BBN-RGD and ^{68}Ga-NOTA-BBN PET imaging. **Results:** Both the primary cancer and metastases showed positive ^{68}Ga-NOTA-BBN-RGD accumulation with high tumor/normal tissue (T/N) ratios. A total of 107 masses were pathologically confirmed, including 24 malignant breast masses, 5 benign breast masses, 16 lymph node metastases, 59 benign lymph nodes, 1 lung metastasis and 2 bone metastases. The sensitivity, specificity, positive, negative predictive values for primary breast cancer were 95.8% (23/24), 60.0% (3/5), 92.0% (23/25), 75.0% (3/4), and 75.0% (12/16), 91.5% (54/59), 70.5% (12/17), 93.1% (54/58) for lymph nodes, respectively. ^{68}Ga-NOTA-BBN-RGD PET/CT detected 23 suspected primary tumor lesions, 12 metastatic lymph nodes, 11 bone metastases, 4 lung metastases and 2 liver metastases with maximum standardized uptake values (SUVmax) of 3.84 ± 2.18, 3.78 ± 1.90, 5.50 ± 2.43, 1.40 ± 1.41 and 4.35, respectively. In comparison, ^{68}Ga-NOTA-BBN PET/CT showed relatively lower SUVmax of 2.31 ± 0.72 for primary tumor, 2.03 ± 0.76 for lymph node metastasis, 2.17 ± 0.57 for bone metastasis, and 1.55 for lung metastasis, P < 0.05). Among them, a total of 52 masses were subjected to immunohistochemical staining against GRPR and integrin αvβ3 confirming moderate correlation between SUVmax in ^{68}Ga-NOTA-BBN-RGD PET and GRPR expression (r = 0.5237, P =0.0012) and weak correlation between SUVmax and integrin αvβ3 expression (r = 0.3733, P = 0.0793). **Conclusion:** This study demonstrated significant uptake of a new type of dual integrin αvβ3 and GRPR targeting in both the primary lesions and metastases of breast cancer. ^{68}Ga-NOTA-BBN-RGD PET/CT may be of great value in discerning both primary breast cancers and metastases, suggesting the potential of ^{68}Ga-NOTA-BBN-RGD PET/CT in breast cancer diagnosis, staging and guiding surgical decision making for the patients.

OP-305

PET Imaging of Chemokine Receptor CXCR4 in Patients with Primary and Recurrent Breast Cancer

T. Vag[1], A. Rossmann[1], S. Metz[1], H. Wester[2], M. Schwaiger[1]; [1]Klinikum Rechts der Isar, Munich, GERMANY, [2]Institute of Pharmaceutical Radiochemistry, Technical University Munich, Munich/ Garching, GERMANY.

Purpose: CXCR4 is a chemokine receptor overexpressed in invasive breast cancer and plays a major role in signaling pathways of metastases. The aim of this study was to assess the feasibility of CXCR4 directed imaging in patients with breast cancer using the novel CXCR4 targeted PET probe ^{68}Ga-Pentixafor. **Material and Methods:** 13 patients with primary breast cancer and five patients with recurrent disease after primary breast cancer underwent CXCR4 targeted PET imaging using ^{68}Ga-Pentixafor. ^{18}F-FDG PET was available in 8 of 18 patients. Maximum standardized uptake values (SUVmax) and tumor-to-background ratios (T/B ratio) of primary tumors or recurrent lesions were measured for both PET probes and compared with each other. SUVmax of CXCR4 targeted PET was also compared with prognostic factors and molecular subtypes of breast cancer. **Results:** 9 of 13 primary breast cancers were visually detectable on ^{68}Ga-Pentixafor PET images (mean SUVmax of 3). The visually undetectable lesions included the two cases of invasive loubular carcinoma (ILC), and two cases of triple negative breast cancer (TNBC). Metastases of recurrent breast cancer were visually detectable in all 5 cases, exhibiting a mean SUVmax of 3.5. ^{18}F-FDG-PET demonstrated higher SUVmax in all patients compared to ^{68}Ga-Pentixafor PET. A significant correlation between SUVmax obtained from ^{68}Ga-Pentixafor PET and prognostic factors including estrogene receptor (ER), progesterone receptor (PR), HER2/neu status, Ki-67 proliferation index, tumor grade and molecular subtypes (luminal A, luminal B, basal like) was not observed. **Conclusion:** CXCR4 directed PET imaging in patients with primary and recurrent breast cancer is feasible, however tumor-detectability is lower compared to ^{18}F-FDG PET. Moreover, we did not find any significant correlation between aforementioned prognostic factors of breast cancer and CXCR4 targeted tracer accumulation. In conclusion, based on these preliminary results in a small patient cohort, CXCR4 targeted PET does not seem to demonstrate any diagnostic or prognostic benefit in Imaging of breast cancer.

Quantitative characterization of xSPECT algorithm: influence of reconstruction parameters (number of iterations and subsets) on image quality

L. Lorenzon[1], A. Fracchetti[1], M. Bonelli[1], M. Tredici[2], V. Zilioli[2], M. Farsad[2], M. Haller[1]; [1]Department of Medical Physics, Hospital of Bolzano, Bolzano, ITALY, [2]Department of Nuclear Medicine, Hospital of Bolzano, Bolzano, ITALY.

Introduction: Recently, Siemens introduced a new reconstruction technique, the xSPECT, which is based on a new algorithm, the Ordered Subset Conjugate Gradient Minimization (OSCGM). The aim of this study was to quantitatively characterize the xSPECT algorithm, by evaluating the influence of reconstruction parameters (number of iteration and subset) on image quality (noise, contrast and contrast-to-noise ratio). **Subject & Methods:** Measurements were performed on the NEMA IEC Body Phantom, filled with a ^{99m}Tc water solution, with a 4:1 sphere-to-background activity concentration ratio. SPECT phantom images were acquired on a Siemens Symbia Intevo 2 and reconstructed using a OSCGM method (xSpect, Siemens Medical Solutions USA, Inc., Malvern, PA), without post-reconstruction filters and varying the number of iterations and subsets. CT image was acquired at 110 kV and 100 mAs/rot, and reconstructed with B31 filter. The SPECT images, reconstructed with different number of iterations and subset, were compared calculating the noise in the homogeneous phantom region, the percentage contrast and the contrast-to-noise ratio, CNR, for the six hot spheres. **Results:** Different behavior has been observed compared to what has been reported in the literature for OSEM reconstruction technique: 1) The number of updates (the product between the subset and the iteration numbers) is not significant for noise level: the noise grows with the number of updates, but the same number of updates can generate different noise levels (t-test, $p < 0.05$). 2) For the same number of updates, the subsets which can be expressed as a power of two (2, 4, 8) generate less noise level than the subsets which are not a power of two (1,3,6,···). 3) Contrast grows with the number of updates, but over 400 updates the noise affects heavily the structures with a diameter larger than 20mm, and their contrast becomes even lower than

that of smaller spheres. 4) CNR decreases rapidly as the number of updates grows. **Conclusion:** The OSCGM reconstruction algorithm, implemented in xSPECT reconstruction technique, behaves differently from OSEM. For the same number of updates, different noise levels may result and the noise is smaller when using a number of subsets that can be expressed as a power of two. A subset number of 2 or 4 is recommended and a low number of updates (<100) in combination with a smoothing filter is suggested in order to preserve contrast and CNR.

OP-310
Dual-labeled PSMA-11 for PET/CT imaging and precise fluorescence guided intraoperative identification of prostate cancer

A. Baranski[1], M. Schäfer[1], U. Bauder-Wüst[1], M. Roscher[1], J. Schmidt[1], E. Stenau[1], T. Simpfendörfer[2], L. Maier-Hein[1], B. Hadaschik[3], U. Haberkorn[2], K. Kopka[1], M. Eder[4,1,5]; [1]German Cancer Research Center, Heidelberg, GERMANY, [2]University Hospital, Heidelberg, GERMANY, [3]University Hospital, Essen, GERMANY, [4]University Hospital, Freiburg, GERMANY, [5]German Cancer Consortium, Heidelberg, GERMANY.

Introduction: Resection of lymph node metastases using image-guided surgery is of high clinical relevance and might have considerable impact on the outcome of metastatic prostate cancer patients. In order to further improve the intraoperative accuracy of detecting PSMA-positive tumor lesions dual-labeled PSMA-inhibitors based on PSMA-11 have been designed. These novel bimodal radiopharmaceuticals allow the combination of preoperative staging by means of PET/CT and fluorescence-guided surgery for a more precise detection of metastasis or neoplastic lymph nodes. **Subjects & Methods:** A series of novel PSMA-11 based optical dye conjugates were synthesized by conjugating the parent molecule PSMA-HBED-CC with FITC, AlexaFluor488, STARRED, DyLight800 and IRDye800CW, respectively. The PSMA-binding and internalization properties were subsequently analyzed in cell based assays using human PSMA expressing LNCaP cells. For the optical investigation of affinity, internalization and intracellular distribution fluorescence was detected by microscopy and flow cytometry. To obtain a preclinical proof-of-concept, specific tumor uptake, pharmacokinetic properties and fluorescence-guided studies were performed in LNCaP (PSMA+) or PC3 (PSMA-) tumor-bearing mice and healthy pigs. **Results:** The radiolabeled fluorescent-dye conjugates showed high affinity in the nanomolar range, PSMA-specific cell uptake and effective internalization into LNCaP cells which has also been confirmed by fluorescence based assays and microscopy. Depending on the fluorescent dye, slightly varying pharmacokinetic properties have been obtained. The ^{68}Ga-labeled FITC-, AlexaFluor488-, DyLight800- and IRDye800CW- conjugates revealed a higher tumor uptake [10.9 ± 0.9 % ID/g (^{68}Ga-PSMA-HBED-CC-FITC), 9.1 ± 6.7 % ID/g (^{68}Ga-PSMA-HBED-CC-AlexaFluor488), 15.7 ± 6.7 % ID/g (^{68}Ga-PSMA-HBED-CC-DyLight800), 13.7 ± 3.7 % ID/g (^{68}Ga-PSMA-HBED-CC-IRDye800CW)] compared to ^{68}Ga-PSMA-11 (4.8 ± 1.3 % ID/g), while a similar uptake was determined for the ^{68}Ga-labeled STARRED- conjugate (5.6 ± 2.3 %lD/g). µPET studies reinforce the PSMA-specific tumor uptake and fast renal clearance of all con-

jugates. The first proof-of-concept studies in mice and healthy pigs revealed a typical organ distribution profile and specific fluorescent signals in PSMA-expressing tissue *in vivo* and *ex vivo* for the clinical relevant candidate PSMA-HBED-CC-IRDye800CW. **Conclusion:** As demonstrated in these preclinical and first *in vivo* proof-of-concept studies, dual-labeled PSMA-11 provides PSMA-specific fluorescence signals and promising pharmacokinetic properties in surgical settings indicating the high potential for future clinical translation. The dual-labeled PSMA-inhibitors investigated in this work might help to establish a novel treatment regimen for a more precise and sensitive pre-, intra- and post-therapeutic detection of prostate cancer. Research Support: We thank PD Dr. med. Arianeb Mehrabi (University Hospital Heidelberg) and his team for supporting the animal studies.

OP-311
SVM based detection of a disease specific metabolic brain pattern in a rat model for Parkinson's disease using longitudinal 18F-FDG PET imaging

M. Devrome[1], M. Crabbé[2], V. Baekelandt[3], K. Van Laere[1], C. Casteels[2], M. Koole[1]; [1]Division of Nuclear Medicine, KU Leuven, Leuven, BELGIUM, [2]Molecular Small Animal Imaging Centre, KU Leuven, Leuven, BELGIUM, [3]Division of Neurobiology and Gene therapy, KU Leuven, Leuven, BELGIUM.

Introduction: Diagnosing the early onset of Parkinson's disease (PD) is of vital importance for treatment and disease follow-up. To study the pathophysiology of PD, animal models that closely resemble the neuropathology and motor symptoms of human PD might play an important role. In this study, a rat model based on the injection of A53T alpha-synuclein rAAV vector was used and a support vector machine (SVM) classifier was applied to identify a PD-specific glucose metabolic brain pattern at a late disease stage. Subsequently, this disease-specific brain pattern was validated by evaluating the pattern expression during various disease stages. **Methods:** Rats were stereotactically injected with recombinant adeno-associated viral vector (rAAV 2/7) in the right substantia nigra, overexpressing either A53T alpha-synuclein (10 rats, PD group) or eGFP (8 rats, control group). Static ^{18}F-FDG PET scans were performed at week 3, 4, 6 and 9 after injection. At week 9, when the dopaminergic degeneration is considered to be complete and stable for the alpha-synuclein injected animals, a SVM classifier was trained to differentiate between the PET scans of the PD and control group. Accordingly, a multivariate PD-characteristic glucose metabolic brain pattern was generated. Consequently, PET scans of both groups performed at earlier time points were projected onto this PD-specific brain pattern to quantify disease progression. Projection-scores of the two groups (alpha-synuclein versus eGFP) were evaluated for statistically significant differences (Wilcoxon rank sum test, at 5% significance level). **Results:** The multivariate PD pattern allowed to identify hypermetabolism in the striatum, frontal cortex, hippocampus and sensorimotor cortex, and hypometabolism in the cerebellum. The Wilcoxon rank sum test demonstrated statistically significant differences between the disease progression scores of the alpha-synuclein

and eGFP group at week 4 (p = 0.006) and at week 6 (p = 0.002). At week 3, differences between the disease progression scores of the two groups were not significant (p = 0.96). These findings demonstrated complete and stable dopaminergic degenerating in this animal model at week 4. **Conclusion:** This study presents a proof-of-concept of a multivariate analysis to identify a disease-specific brain pattern based on preclinical ^{18}F-FDG brain PET imaging. Correlations with motor dysfunction parameters over time and comparison with univariate data analysis will further validate this PD-specific metabolic brain pattern as an imaging biomarker for monitoring disease progression and therapeutic interventions in rodent disease models using longitudinal ^{18}F-FDG brain PET imaging.

OP-312

Quantitative myocardial stress perfusion in patients with chest pain and normal coronary arteries to assess subsequent improvement of symptoms with transcutaneous electrical nerve stimulation

A. G. Monroy-Gonzalez[1], M. J. L. De Jongste[1], E. Alexanderson-Rosas[2], R. A. Tio[1], R. H. J. A. Slart[1]; [1]University Medical Center Groningen, Groingen, NETHERLANDS, [2]Department of Physiology, National Autonomous University of Mexico, MEXICO.

Introduction: Cardiac Syndrome X (CSX) is defined as the combination of chest pain and positive exercise stress test in the presence of normal coronary arteries. Improvement of symptoms in patients with CSX through Transcutaneous Electrical Nerve Stimulation (TENS) has been reported. However, the relationship of myocardial stress perfusion with PET and clinical response to TENS in patients with chest pain and normal or near normal coronary arteries is still unknown**. Aim:** We evaluated the role of absolute myocardial stress perfusion quantification with Nitrogen-13 ammonia PET in predicting good response to treatment with TENS in patients with normal or near normal coronary arteries. **Methods:** We retrospectively included 41 patients who underwent Nitrogen-13 ammonia PET for quantification of myocardial blood flow (MBF), during stress with adenosine. Patients with significant coronary artery disease (>50% stenosis) demonstrated by invasive coronary angiography were excluded. **Results:** In our population mean age was 51±10 years old, 66% of patients were female, 7% were diabetic, 34% had hypertension, and 10% were current smokers. In our population 51% of patients reported improvement of symptoms. We did not find clinical significant differences in baseline characteristics of patients with and without improvement of symptoms. However, we found an increased proportion of patients with abnormal MBF during stress in patients without improvement of symptoms when compared to patients with improvement of symptoms (50% [n=10] vs. 19% [n=4] respectively, p value = 0.04). Furthermore, we found an increased proportion of patients with the use of beta-blockers in patients with improvement of symptoms when compared to patients without improvement of symptoms (42% [n=9] vs. 10% [n=2] respectively, p value = 0.02). **Conclusion:** Absolute myocardial stress perfusion quantification and the use of beta-blockers might predict

improvement of symptoms in patients with normal or near normal coronary arteries treated with TENS. Further studies are needed in order to fully understand the role of myocardial stress perfusion in this group patients.

OP-313

TSPO-PET for high-grade glioma imaging using the novel ligand [^{18}F]GE-180 - first in human results in the course of radiotherapy

M. Unterrainer[1], D. Fleischmann[1], S. Lindner[1], A. Brunegraf[1], F. Vettermann[1], L. Vomacka[1], M. Brendel[1], R. Rupprecht[2], C. Belka[1], P. Bartenstein[1], M. Niyazi[1], N. Albert[1]; [1]Ludwig-Maximilian-University Munich, München, GERMANY, [2]University of Regensburg, München, GERMANY.

Objective: The 18-kDa mitochondrial translocator-protein (TSPO) was reported to be upregulated in high-grade gliomas (HGG). [^{18}F]GE-180, a novel 3rd generation TSPO receptor ligand, has shown an improved target-to-background contrast. Therefore, we evaluated the feasibility of [^{18}F]GE-180 PET in HGG patients, its potential for clinical use before radiotherapy and the impact of radiotherapy on the tumoral TSPO expression. **Methods:** 12 patients with histologically confirmed HGG (11 glioblastoma, 1 anaplastic astrocytoma; IDH-wildtype) underwent [^{18}F]GE-180 PET at initial diagnosis or recurrence before radiotherapy (6 medium- and 6 high-affinity binders (MAB, HAB)). The PET parameters mean background uptake (SUV_{BG}), maximal tumor uptake (SUV_{max}), maximal tumor-to-background ratios (TBR_{max}) and biological tumor volumes (BTV) using different thresholds (SUV_{BG} x 1.6, 1.8 and 2.0) were evaluated in the 60-80 minutes p.i. summation images. The different BTVs were compared to the MRI-based gross tumor volume (GTV). Follow-up PETs were performed in 8/12 patients 4-6 weeks after radiotherapy and compared to the baseline PET. **Results:** All HGG showed [^{18}F]GE-180 uptake with extraordinary high tumor-to-background contrast (median SUV_{max} 3.1 (2.5 - 5.8) and TBR_{max} 6.9 (3.9 - 9.1). No difference between HAB and MAB regarding the uptake-characteristics could be observed (p>0.05). Volumetric comparisons with GTV revealed significantly larger BTVs (p=0.002/0.003/0.008) with high [^{18}F]GE-180 uptake beyond contrast-enhancement. The spatial volumetric correlation (Sørensen-Dice coefficient) of BTVs and GTV before radiotherapy was 0.48 (BTV1.6), 0.54 (BTV1.8) and 0.58 (BTV2.0). After radiotherapy, a significant reduction of SUV_{max} (median percental reduction of 43.4% (1.1% - 61.1%), p=0.012) and of TBR_{max} (median percental reduction of 27.9% (14.1% - 54.8%), p=0.012) could be observed. All but one patients provided significant reductions of the BTVs (e.g. median percental reduction of BTV1.6: 63.2%, p=0.017). In sum, 1 patient showed an increase of 34.8% despite undergoing radiotherapy, 5 patients showed a reduction ranging between 26.1% and 63.2%, whereas 2/8 patients showed a nearly complete remission of the extent of TSPO expression (92.0% and 94.7%). **Conclusion:** This first study using [^{18}F]GE-180 in HGG patients shows a remarkably high tumor-to-background contrast. As high TSPO expression was shown in areas beyond contrast enhancement on MRI, [^{18}F]GE-

180 PET represents a promising tool for HGG delineation (with a potential influence on therapy planning). The tumoral TSPO expression was differently affected by radiotherapy, hence [18F] GE-180 PET might serve as a complementary imaging-biomarker for response assessment in HGG. [18F]GE-180 PET is of utmost interest regarding future clinical applications in terms of treatment planning and response assessment.

OP-314

Relationship between Intraprostatic Hybrid Tracer Deposition and Lymphatic Drainage Pattern in Prostate Cancer Patients

C. M. de Korne[1], T. Buckle[1], N. S. van den Berg[1], J. de Jong[2], R. A. Valdés Olmos[1], F. W. B. van Leeuwen[1], H. G. van der Poel[2]; [1]LUMC, Leiden, NETHERLANDS, [2]NKI-AVL, Amsterdam, NETHERLANDS.

Introduction: Defining the sentinel node (SN) in prostate cancer is complex as drainage may differ between segments within the prostate. While the SN procedure is based on visualization of the first tumor draining lymph node, the location of the primary tumor is currently not taken into account during tracer administration. Hence, discrepancies between the migration route of metastasizing cancer cells and the drainage pattern of the injected tracer might occur, resulting in false negative results. This study was designed to expand on an initial 19 patients proof-of-concept study[1] and aimed to evaluate the ability of the SN procedure to predict the location of lymphatic metastases based on the primary tumor site. **Methods:** 70 patients with prostate carcinoma, scheduled for robot assisted laparoscopic prostatectomy (RALP) and extended lymph node dissection with SN biopsy, were included in this study. After injection of Indocyanine green (ICG)-99mTc-nanocolloid in the peripheral zone of the prostate, SLN mapping was performed based on lymphoscintigraphy and SPECT/CT. SNs were resected using a combination of radio- and fluorescence guidance. Pathology was used to determine the primary tumor and metastatic spread. Fluorescence imaging of paraffin-embedded prostate tissue allowed visualization of the tracer deposits in the prostate. This deposition was related to the intraprostatic and lymphatic tumor spread. **Results:** In total 252 SNs and 552 non-SNs were identified. The distribution of the SNs within the pelvis was shown to correlate to the intraprostatic location of tracer administration. In 80% of the ten lymph node positive patients, positive SNs were found, with a total of 19 SNs. Two of these patients also had tumor positive non-SNs. In two patients positive non-SNs were found, without finding tumor positive SNs. In all patients, the primary tumor location could be related to the locations of lymphatic spread. **Conclusion:** The correlation between the tracer deposits within the prostate, the location of the primary tumor and the number and anatomical position of the SNs indicates that placement of tracer deposits is of influence on the visualized lymphatic drainage pattern. Moreover, the correlation between the location of the primary tumor and the location of the positive SNs suggested that placement of tracer deposits near the primary tumor site is beneficial for the identification of metastatic spread. OP-315

Efficacy and Safety of 177Lu-PSMA-617 Treatment in Castration Resistant Prostate Cancer with Organ Metastasis

O. E. Sahin[1], E. Akgün[1], E. Demirci[2], M. Ocak[3], A. Akgün[1], B. Akovalı[1], E. Karayel[1], H. Pehlivanoglu[1], L. Kabasakal; [1]Department of Nuclear Medicine, Cerrahpasa Medical Faculty, Istanbul University, İstanbul, TURKEY, [2]Department of Nuclear Medicine Sisli Etfal Training and Research Hospital, İstanbul, TURKEY, [3]Department of Pharmaceutical Technology, Pharmacy Faculty, Istanbul University, İstanbul, TURKEY.

Purpose: PET imaging with radiolabeled inhibitors of prostate-specific membrane antigen (PSMA) have been successfully used for imaging prostate cancer and become widespread during the recent years. Therefore PSMA targeted radionuclide therapy is increasingly being popular and using for people with advanced prostate cancer. The median survival of castration resistant prostate cancer patients with liver metastasis is reported to be 6 months which is one of the shortest median survival in prostate cancer subgroups. The aim of our study was to determine the effect of Lu177 PSMA treatment on survival and evaluate the side effects in hormone refractory prostate cancer patient with organ metastases. **Materials and Methods:** Records of patients who treated with 177Lu-PSMA-617 at our hospital from 2014 to 2016 were retrospectively examined. CRPC patients who treated with 177Lu-PSMA-617 and there wasn't clinical respond after the standard chemotherapies including docetaxel and abiraterone were included in the study. Survival rates were calculated from the first day of administered therapy. In addition, treatment nephrotoxicity was assessed by creatinine levels and hematotoxicity was assessed by using SWOG criteria. **Results:** 19 patients (median age 67.7 ± 8.1 years, range 55-82) meeting the inclusion criteria within the study timeline were included the study. 4 patients (18.2%) underwent radical prostatectomy,16 patients (84.2%) underwent curative or palliative radiotherapy. A total of 18,8 ±9,4 GBq (*average* cycle : 3 ,range :1-5) were performed in 19 patients. 16 patients (84.2%) had liver metastasis and 6 patients (31.6%) had lung metastasis before the therapy. Furthermore 18 patients (94.7%) had bone metastasis. The mean tPSA values before the therapy was calculated 557 (6 - 4499) ng/ml. Among patients whose PSA levels were regularly monitored (n:16) decreased PSA levels were seen in 6 patients (38%) and increased PSA levels were seen in 10 patients (62%). A 3,5% increase in serum creatinine was observed compared to initial levels. In 17 patients whom hematologic data could be evaluated according to SWOG criteria, grade 1 hematotoxicity were observed in 5 patients (29%) and grade 2 hematotoxicity were observed in 1 patient (6%).The median overall survival for all patients was calculated 8 months (95% Cl:5,2-10,8). **Conclusion:** 177Lu-PSMA-617 treatment is known that effective for advanced staged castration resistant prostate cancer with lymph nodes and bone metastasis. Our study show that 177Lu-PSMA-617 treatment can be safely used for patients who have castration resistant prostate cancer with organ metastasis.

Characterization of ^{111}In-labeled site-specifically conjugated anti-PSMA antibody-drug conjugates for treatment of PSMA-expressing tumors

S. Lütje[1,2], D. Gerrits[1], J. D. Molkenboer-Kuenen[1], K. Herrmann[2], G. Fracasso[3], M. Colombatti[3], O. C. Boerman[1], S. Heskamp[1]; [1]Dept. Radiology and Nuclear Medicine, Radboud university medical center, Nijmegen, NETHERLANDS, [2]Clinic for Nuclear Medicine, University Hospital Essen, Essen, GERMANY, [3]Dept. of Medicine, University of Verona, Verona, ITALY.

Aim: Prostate cancer (PCa) is the most common cancer in men worldwide. In advanced stages of the disease, PCa responds

poorly to chemotherapy. Therefore, antibody-drug-conjugates (ADCs) have been developed to allow specific and improved delivery of highly cytotoxic drug to the tumor. As the prostate-specific membrane antigen (PSMA) is overexpressed in PCa, it represents a promising target for ADC-based therapies. The aim of this study was to evaluate the therapeutic efficacy of site-specifically conjugated duocarmycin- and monomethyl auristatin E (MMAE)-based anti-PSMA ADCs with drug-antibody-ratios (DARs) of 2 and 4. **Materials and Methods:** The anti-PSMA antibody D2B was chemoenzymatically conjugated with duocarmycin or monomethyl auristatin E (MMAE) via the glycosylated site of the antibody. Preservation of the immunoreactivity of the antibody upon site-specific conjugation was investigated in vitro. Biodistribution studies and microSPECT/CT imaging (18.5 ± 2.6 MBq) with 25 μg of ^{111}In-labeled ADCs were performed in BALB/c nude mice with s.c. PSMA^{+} LS174T-PSMA xenografts. Finally, the therapeutic efficacy of the four different ADCs was assessed in mice with s.c. LS174T-PSMA tumors. **Results:** The immunoreactivity of the anti-PSMA antibody was preserved upon site-specific conjugation with the drugs. Biodistribution revealed high tumor uptake of all ADCs. ^{111}In-DTPA-D2B-DAR2-MMAE showed the highest tumor uptake, reaching 119.7 ± 37.4 %ID/g at 3 days p.i.. Tumors of mice treated with ^{111}In-DTPA-D2B, ^{111}In-DTPA-D2B-DAR2-duocarmycin, ^{111}In-DTPA-D2B-DAR4-duocarmycin, ^{111}In-DTPA-D2B-DAR2-MMAE, and ^{111}In-DTPA-D2B-DAR4-MMAE could clearly be visualized with microSPECT/CT. In contrast to 'naked' D2B or vehicle, D2B-DAR2-duocarmycin and D2B-DAR4-duocarmycin, treatment with D2B-DAR2-MMAE and D2B-DAR4-MMAE significantly impaired the tumor growth and prolonged median survival from 13 days (PBS) to 20 and 29 days, respectively. Tumor doubling time increased from 3.5 ± 0.5 days to 5.2 ± 1.8 and 9.2 ± 2.1, after treatment with D2B-DAR2-MMAE and D2B-DAR4-MMAE, respectively. **Conclusion:** The site-specifically conjugated anti-PSMA ADCs D2B-DAR2-MMAE and D2B-DAR4-MMAE efficiently targeted PSMA-expressing xenografts, effectively inhibited tumor growth of PSMA-expressing tumors, and significantly prolonged survival of mice.

OP-337

Novel high affinity affibody for radionuclide imaging of VEGFR2 in glioma vasculature: proof-of-principle in murine model

B. Mitran[1], R. Güler[2], F. P. Roche[1], E. Lindström[1], R. Selvaraju[1], F. Fleetwood[2], S. S. Rinne[1], L. Claesson-Welsh[1], V. Tolmachev[1], S. Ståhl[2], A. Orlova[1], J. Löfblom[2]; [1]Uppsala University, Uppsala, SWEDEN, [2]KTH-Royal Institute of Technology, Stockholm, SWEDEN.

Aim: Glioblastomas are rapidly growing, highly malignant brain tumors with limited therapeutics options. Due to the high vascularization of these tumors, the inhibition of angiogenesis has become an attractive therapeutic strategy in recent years. Vascular endothelial growth factor receptor-2 (VEGFR2) is a promising target for anti-angiogenic drugs. However, the successful implementation of anti-VEGFR2 therapies

requires patient stratification. The new VEGFR2 antagonistic biparatopic affibody molecule HEHEHE-ZVEGFR2-Bp2-NODA-GA (denoted as Z_{VEGFR2}-Bp$_2$, 14.4 kDa) with picomolar affinity to VEGFR2 was recently presented and demonstrated successful targeting in vivo. The aim of this study was to evaluate the biparatopic affibody construct Z_{VEGFR2}-Bp$_2$ for imaging of VEGFR2 expression in glioblastoma orthotopic tumors. **Methods:** Female C57BL/6 mice with intracranial gl261 glioma tumors were used to study the imaging properties of ^{111}In-Z_{VEGFR2}-Bp$_2$ in glioblastoma orthotopic model. The mice with MRI confirmed tumors were imaged at 2 h pi of ^{111}In-Z_{VEGFR2}-Bp$_2$ (23 MBq, 4 μg). To confirm targeting specificity, additional groups of mice were injected with 40 μg of ^{111}In- Z_{VEGFR2}-Bp$_2$ (to saturate VEGFR2 in tumor vasculature) or 4 μg of ^{111}In-Z_{taq}-Z_{taq} (size matching non-targeting affibody construct). Radioactivity distribution in brain sections was studied using autoradiography and VEGFR2 expression was assessed by immunofluorescent staining. **Results:** Intracranial orthotopic gl261 tumors were visualized using SPECT/CT. Very low radioactivity uptake was found in healthy CNS tissue. The radioactivity uptake in the tumor areas delineated by MRI was significantly higher than in the normal brain. Radioactivity uptake was also detected in lateral ventricles and pineal gland but it was significantly lower than in tumors. The tumor-to-cerebellum ratios after the injection of 4 μg ^{111}In-Z_{VEGFR2}-Bp$_2$ (3.8±0.9) were significantly (p <0.05) higher than the ratios observed for the 40 μg injected dose (2.1±0.7) and for the non-targeting conjugate (2.2±0.5). Microautoradiography of cryosectioned CNS tissue was in good agreement with SPECT/CT images. H&E staining of the slides after autoradiography confirmed the presence of tumor tissue in areas with elevated radioactivity uptake. Tumor-to-brain ratios based on autoradiography results were in agreement with SPECT/CT images (20±6 for 4 μg ^{111}In-Z_{VEGFR2}-Bp$_2$, 7±3 for 40 μg ^{111}In-Z_{VEGFR2}-Bp$_2$ and 3.5±0.9 for 4 μg ^{111}In-Z_{taq}-Z_{taq}). VEGFR2 staining with immunofluorescence showed a high vascularization specific to glioblastomas. **Conclusion:** ^{111}In-Z_{VEGFR2}-Bp$_2$ appears to be a promising probe for in vivo noninvasive visualization of tumor angiogenesis in glioblastoma.

Introduction: The Gonadotrophin-releasing hormone (GnRH) receptor density may mirror early pathologic changes leading to Alzheimer Disease (AD).[1-2] A GnRH SPECT radiotracer will contribute to the understanding of molecular disease mechanisms. **Materials and Method:** Twenty analogues were synthesized using an approach of late-stage diversification via cupper-catalysed azide-alkyne cycloreaction (Cu-AAC) and were evaluated in vitro by competitive binding assays using recombinant cells overexpressing the GnRH receptor complex.[3] We sought a route to introduce a long-lived radionuclide into the structures to allow straightforward biological characterisation. A modification of the Cu-AAC by Yan and co-workers was used, which proceeds via Cu^{II} reduction to the active cyclisation catalyst Cu^{I} by radioiodide, followed by trapping of an anionic transition state by $^{123}I^{+}$ during the cyclisation reaction. In addition as a continuation of the initial screening for GnRH-antagonists, another promising radiotracer-candidate emerged. This candidate was assessed for radioiodination based on different chain lengths by an anchimerically-assisted Finkelstein reaction. This highly promising radiotracer candidate was evaluated *in vitro* by binding assays to inhibit human GnRHR, *ex vivo* by rat gonadal and brain tissue section autoradiography, as well as *in vivo* by brain SPECT/CT imaging and biodistribution studies. **Result and Discussion:** Several promising GnRH receptor-antagonists with nM affinity have been developed.[3] Two GnRH receptor-antagonists were radiolabelled with ^{123}I by optimisation of the Cu-AAC radioiodination reaction. In addition, we found that the anchimerically-assisted Finkelstein reaction, which is an obvious candidate for application in late stage radiolabeling, has a great potential as a radiolabeling method. We have evaluated the reaction rate and how the contribution of anchimeric-assistance affects the halide exchange in the Finkelstein reaction. One compound has been successfully radiolabeled with ^{123}I by the anchimerically-assisted Finkelstein reaction and evaluated *in vitro* showing nM affinity to human GnRHR. Autoradiography in tissue sections determined the *ex vivo* receptor binding properties. Brain SPECT/CT imaging and biodistribution studies revealed the in vivo radiotracer biodistribution pattern post-injection. **Conclusion:** We have successfully synthesized and evaluated biologically a radioiodinated GnRHR antagonist with ^{123}I for further evaluation in imaging studies. *Ongoing study - Patent application number 1704681.4 IPO/UK* 1.Meethal,S.;Smith,M.; Bowen,R.;Atwood,C.,The gonadotropin connection in Alzheimer's disease. *Endocrine* 2005, *26* (3), 317-325. 2.Webber,K.M.;Perry,G.;Smith,M. Somatostatin receptor type 2 as a marker for pro-inflammatory macrophages

S. T. van Tiel, L. Utomo, E. J. Meester, J. de Swart, N. Kops, R. H. de Blois, M. de Jong, Y. Bastiaansen-Jenniskens, M. Bernsen; ErasmusMC, Rotterdam, NETHERLANDS.

Aim: To explore if the Somatostatin receptor type 2 (SSTR2) can be a marker for pro-inflammatory macrophages. **Materials and Methods:** Expression of SSTR2 by pro-inflammatory macrophages (IFNγ+TNFα stimulated) and human arthritic synovium, stimulated towards acute inflammation, was determined by quantitative PCR analysis. Experimental osteoarthritis (OA) was induced in mice by destabilization of the medial meniscus (DMM). The mice were euthanized between 1 and 56 days after OA induction and harvested knees were stained for F4/80 and iNOS expression to visualize (pro-inflammatory) macrophages. Specific binding of the ^{111}In-JR11 SSTR2-tracer was tested by an autoradiography assay on tissue sections from frozen human synovium. Binding of the SSTR2-tracer to pro-inflammatory macrophages is determined by an uptake assay. **Results:** SSTR2 expression was significantly higher in pro-inflammatory macrophages compared to unstimulated macrophages. SSTR2 levels were also measured in OA synovial tissue and in OA synovial tissue stimulated with IFNγ+TNFα to simulate acute inflammation. Similarly to stimulated cultured macrophages, SSTR2 was expression was significantly higher in IFNγ+TNFα stimulated arthritic synovium compared to unstimulated arthritic synovium. Immunohistochemical analysis of knees from DMM mice indicated that F4/80+ macrophages were distinctly present from day 3 onwards in developing OA in a mouse knee. The number of F4/80+ macrophages was significantly higher at day 3 than at day 1 and remained elevated until day 28, before returning to baseline at day 56. In the DMM knees, iNOS+ cell peaked between day 3 and 7 before and returned to baseline after day 14. Tracer binding studies indicated specific tracer uptake at elevated levels in cultured pro-inflammatory macrophages and synovium stimulated with IFNγ+TNFα compared to unstimulated macrophages or synovium. **Conclusion:** The Somatostatin receptor type 2 is present on pro-inflammatory macrophages and may be a marker to study macrophage activation in in vitro experiments.

Quantitative Analysis of 99mTc-DMSA Renal Scintigraphy of Animal AKI Models; Comparison with Histopathological and Biochemical Assays

K. Tanha[1], H. Fatemikia[2], M. Seyedabadi[1], K. Tanha[3], Z. Karimi[4], M. Assadi[1]; [1]The Persian Gulf Nuclear Medicine Research Center, Bushehr University of Medical Sciences, Bushehr, IRAN, ISLAMIC REPUBLIC OF, [2]Department of Physiology, Medical School, Bushehr University of Medical Sciences, Bushehr, IRAN, ISLAMIC REPUBLIC OF, [3]Department of Biostatistics, School of Public Health, Iran University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF, [4]Shiraz Nephron Urology Research Center, Shiraz University of Medical Sciences, Shiraz, IRAN, ISLAMIC REPUBLIC OF.

Purpose: Acute kidney injury (AKI) in pre-clinical studies is commonly evaluated by biochemical markers such as blood urea nitrogen (BUN) and serum creatinine (Cr) along with histological examinations. In this study, we compared 99mTc-DMSA renal scintigraphy with biochemical and histopathological methods in two animal models of acute kidney injury. **Methods:** Nephrotoxicity was induced either by gentamicin (100mg/Kg/day for one week) or unilateral ureteral ligation (UUO). Renal scintigraphy was performed after intravenous injection of 99mTc- DMSA. Furthermore, plasma levels of blood urea nitrogen (BUN), creatinine, sodium, and potassium were determined. At the end of experiments, kidneys were excised for the measurement of activity uptake (mCi/gr) using a dose calibrator as well as histopathological examinations with hematoxylin and eosin (H&E) staining. **Results:** There was a significant decrease in 99mTc-DMSA uptake in both gentamicin and UUO groups, and it was more significant in the former. The levels of BUN and creatinine increased in both gentamicin and UUO groups, while the levels of sodium and potassium remained unchanged. Furthermore, a strong correlation was found between DMSA uptake and histopathological findings. **Conclusion:** Scintigraphy with 99mTc-DMSA is capable of detection of kidney injury in both gentamicin and UUO groups. Moreover, a significant correlation was found between scintigraphy parameters and histopathological findings. This suggests 99mTc-DMSA as a non-invasive method for the evaluation of kidney injury induced by drugs or anatomical disorders in pre-clinical studies. **Table 1.** Biochemical analysis of plasma levels of BUN, creatinine, sodium and potassium and results of tissue Tc-99m DMSA uptake in the GM, GMS, UUO and UUOS groups.

OP-341

PET/CT And SPECT/CT Based Identification of Novel Rodent BAT and Beige Depots-An Image Guided Exploration Of Human-like Thermogenic Tissues in Mice

O. K. Oz[1], F. Zhang[1], G. Hao[1], G. Hassan[1], M. Shao[1], Y. An[1], Q. Wang[1], C. Kusminski[1], K. Nham[1], Q. Zhai[2], P. Scherer[1]; [1]UT Southwestern Medical Center, Dallas, TX, UNITED STATES OF AMERICA, [2]Key Laboratory of Nutrition and Metabolism, Institute for Nutritional Sciences, Shanghai Institutes for Biological Sciences, Chinese Academy of Sciences, Shanghai, CHINA.

Aims: 18F-FDG (FDG) PET/CT imaging in humans has been invaluable to visualize active thermogenic adipose tissue. These depots are of interest due to their potential for anti-diabetic and anti-obesity effects. It is well known that mice display a prominent brown fat pad in the interscapular region (iBAT). We embarked on a systematic effort to map so far uncharacterized fat pads in mice, investigating the potential of 18F-FDG glucose and 123/125I-BMIPP fatty acid uptake as imaging guidance tools to isolate these "human-like thermogenic" depots in mice. **Materials and Methods:** Following an overnight fast, wild-type mice (n=3/group/tracer) were subjected to whole body FDG-PET/CT (~37MBq FDG/mouse, 1h uptake period, Siemens Inveon PET/CT) or 123/125I-BMIPP SPECT/CT (~175MBq/mouse, 1h uptake period, BioScan NanoSPECT/CT). In some instances mice were pre-treated for 7 days with the β3 adrenergic receptor agonist,

CL 316,243. To demonstrate that FDG or BMIPP avid sites were adipose tissue, imaging studies were carried out in the FAT-AT-TAC mouse, an inducible adipose tissue ablation model. Images guided the dissection of fat depots for histology and RNA extraction with subsequent cDNA preparation. Respective molecular markers were: brown adipose tissue: *Zic1, UCP1, Lhx8;* beige adipose tissue: *Cited1, Cd137, Epsti1, Tbx1, Tmem26*; white adipose tissue: *Tcf21.* **Results:** Both FDG-PET/CT and *I-BMIPP SPECT/CT images revealed a strong uptake in the classical iBAT. We also found regions with high metabolic activity in clavicular (supra- and infra-), cervical, axillary, scapular (supra- and infra-), spinal (pre-vertebral), inter-centrodorsal musculature posterior to spine areas and within the thigh. The β3 adrenergic receptor agonist treatment enhanced FDG and *I-BMIPP uptake. Fat depots (e.g. the inguinal, axillary anterior subcutaneous chest as well as the supraspinal fat pads) prone to absorb fatty acids as a fuel and prone to beiging were better demonstrated on the fatty acid images. FAT-ATTAC mice lost these areas of activity upon fat ablation proving their identity as adipose. Histological analysis and marker gene identification further validated and characterized these novel fat pads as brown-, beige or white-adipose tissue. **Conclusions:** The combination of FDG and *I-BMIPP image guided dissection with histological characterization and marker gene expression patterns indicate that rodents show a surprising topological similarity to regions of brown and beige adipogenesis in humans. These studies also demonstrate the utility of fatty acid SPECT/CT imaging in identifying metabolically active fat depots. Our imaging paradigm maybe useful to screen drugs as regulators of fat metabolism for obesity and diabetes treatments.

OP-342

SPECT-MRI and histological analysis to map PRRT radiobiology for a better understanding of local treatment effects

J. Nonnekens, G. N. Doeswijk, J. C. Haeck, M. W. Konijnenberg, D. C. van Gent, M. de Jong; Erasmus MC, Rotterdam, NETHERLANDS.

Aim: Radiobiological principles of external beam radiotherapy have been studied for decades, while the radiobiology of peptide receptor radionuclide therapy (PRRT) is still in its infancy. During PRRT of metastasized neuroendocrine tumors (NETs) with overexpression of somatostatin receptors, Lutetium-177 is targeted to the tumor via coupling to the somatostatin analogue DOTA-[Tyr3]octreotate (177Lu-DOTA-TATE). Lutetium-177 will induce DNA damage leading to tumor cell death with limited harm to healthy tissues. Patient treatment strongly increases progression-free survival and life quality. There is nevertheless still room for improvement, as very few patients are cured at this stage of disease. For possible future therapy optimizations, it is essential to have a better understanding of local treatment (side) effects, both in tumor and healthy tissues. To gain insight in the underlying radiobiological principles, we studied PRRT effects in mice using SPECT/MRI imaging, biodistribution, histological analysis and dosimetric calculations. **Materials and Methods:** 40 Balb/c nu/nu mice with SSTR-positive H69 xeno-

grafts were injected with a therapeutic dose of ^{177}Lu-DOTA-TATE (30MBq/0.5µg), 4 uninjected mice served as controls. Animals were grouped per 4 and sacrificed at 1 hour or 1, 2, 3, 4, 5, 7, 9, 11 or 14 days after injection. 1 animal per group was scanned with SPECT/MRI (Nanoscan, Mediso) and from all 4 animals/group organs/tumors were collected for *ex vivo* biodistribution, dosimetry and histological analysis. Organs were conserved in formalin or frozen. Furthermore, the bone marrow was extracted and prepared on cytospins. Paraffin sections were prepared for histological analysis: hematoxylin and eosin staining for morphology and immunofluorescence staining for DNA damage and cell death parameters. **Results:** SPECT/MRI imaging showed the distribution in the different organs over time which correlated well to the *ex vivo* biodistribution data. Kidney uptake was high 1h after injection (tumor-to-kidney ratio 1.0±0.2), but quickly declined over time, while tumor uptake remained high (tumor-to-kidney ratio 10.1±2.5 at day 9). DNA damage was observed in tumors until the latest time point studied (as measured with DNA double strand break markers gamma-H2AX and 53BP1). Apoptosis increased over time in the tumors (measured with TUNEL staining). Bone marrow DNA damage (due to circulating radionuclides) was observed at 1h and 1 day after injection **Conclusion:** With this study, we studied in detail the radiobiology of PRRT in a preclinical setting. Our results will contribute to a better understanding of PRRT effects, which might help to improve future patient treatment.

OP-343

Comparison study of TCO-functionalized vector systems for *in vivo* click chemistry using [^{111}In]In-DOTA-Tetrazine

P. E. Edem[1,2], J. T. Jørgensen[1,2], K. Nørregaard[1,2], E. J. L. Stéen[2], R. Rossin[3], A. Birke[4], C. Denk[5], A. Yazdani[6], J. F. Valliant[6], H. Mikula[5], M. Barz[7], M. Robillard[3], M. M. Herth[1,2], A. Kjær[1,2]; [1]Rigshospitalet, Copenhagen, DENMARK, [2]University of Copenhagen, Copenhagen, DENMARK, [3]Tagworks Pharmaceuticals, Eindhoven, NETHERLANDS, [4]Johannes Gutenberg-University Mainz, Mainz, GERMANY, [5]TUWien, Vienna, AUSTRIA, [6]McMaster University, Hamilton, ON, CANADA, [7]Johannes Gutenberg-University Mainz, Maiz, GERMANY.

Purpose/Introduction: *In vivo* click using the inverse electron demand Diels-Alder (iEDDA) reaction between a radiolabelled tetrazine (Tz) and *trans*-cyclooctene (TCO) has gained interest for pretargeted imaging. This technique was first implemented using an ^{111}In-labelled Tz and a TCO functionalized antibody to image colorectal cancer xenografts in murine models. Different radiolabelled tetrazines have since been reported, however evaluation of the accompanying *in vivo* click reaction is often lacking. This can be attributed to high costs and/or the time consuming nature in producing validated TCO-functionalized vectors in suitable animal models. Herein we compare 3 previously reported TCO-functionalized vectors and 2 new TCO functionalized polymer vectors using the ^{111}In-labelled tetrazine for pretargeted imaging with microSPECT/CT. **Subjects and Methods:** TCO functionalized mesopourous silica nanoparticles (MSN-TCO) targeting the lungs, bisphosphonates (BP-TCO) targeting bone, and antibodies (CC49-TCO) targeting tumours, were prepared as previously described.

Two TCO modified polymers: polyglutamic acid (PGA) and PGA graft copolymers functionalized with polysarcosine (PSar) were prepared, giving PGA-TCO and PGA-PSar-TCO respectively. The 1,4,7,10-tetraazacyclododecane-1,4,7,10-tetraacetic acid (DOTA) functionalized tetrazine was radiolabelled with indium-111 giving [^{111}In]In-DOTA-Tz (RCC 93-99%). Healthy BALB/c mice were administered with MSN-TCO (i.v.) or BP-TCO (i.v.), while mice bearing subcutaneous human colorectal (LS174T) xenografts or murine colorectal (CT26) tumours were administered CC49-TCO (i.v.) or the polymers (i.t.), respectively. After various time points the [^{111}In]In-DOTA-Tz was administered intravenously and SPECT/CT images were obtained at 2-3 and 22-24 h p.i. RESULTS: SPECT/CT revealed radioactivity accumulation in the lungs in mice pretreated with MSN-TCO and bone accumulation in mice pretreated with BP-TCO at 2 h and 22 h p.i. The amount of lung uptake varied for each animal, while the amount of bone uptake was more consistent. Tumour uptake was observed in mice pretreated with CC49-TCO at 2 h p.i. with improved contrast at 22 h p.i. In the case of PGA-PSar-TCO, tumour uptake was observed at 22 h p.i. while very little tumour uptake was observed in mice pretreated with PGA-TCO at either time-point. **Discussion/Conclusion:** We have shown pretargeted SPECT/CT imaging can be performed using different TCO functionalized vectors in both healthy and tumour bearing murine models using [^{111}In]In-DOTA-Tz. For healthy mice, BP-TCO was preferred over MSN-TCO due to its easier preparation and formulation. This led to improved reproducibility and good image contrast at early time-points. For the tumour models, PGA-PSar-TCO offered a cheaper and easier to synthesize alternative to CC49-TCO while maintaining good image contrast at similar time-points.

Functional Carbon11-Methionine and Fluorine18-Fluorodeoxyglucose PET/CT parameters in patients with multiple myeloma in a first disease staging setting: could they reflect the underlying pathophysiology?

C. Caldarella[1], D. Ripani[2], D. Pizzuto[2], T. Za[3], V. De Stefano[3], A. Giordano[2]; [1]Nuclear Medicine Unit and PET-CT Center, Policlinico "A.Gemelli", Rome, ITALY, [2]Institute of Nuclear Medicine, Università Cattolica del Sacro Cuore "A.Gemelli", Rome, ITALY, [3]Hematology Service, Università Cattolica del Sacro Cuore "A.Gemelli", Rome, ITALY.

Introduction: Carbon11-Methionine PET/CT (MET-PET) has proved to be a more sensitive tool than Fluorine18-Fluorode-oxyglucose PET/CT (FDG-PET) in evaluating multiple myeloma (MM) patients at first disease staging. Functional PET-derived parameters may be useful to depict the uptake degree of lesions in addition to visual evaluation. Aim of our study was to determine whether MET-PET and FDG-PET functional parameters in the same patients reflect the underlying pathophysiology in terms of bone marrow (BM) involvement and monoclonal Ig (mIg) production. **Subjects & Methods:** Patients with MM undergoing MET-PET and FDG-PET for first disease staging were included. Data regarding % plasma cell BM involvement and their immunological surface phenotype (%CD138), presence of serum/urine mIg, serum free-light-chains (FLCs) and their ratios were collected. Functional parameters were obtained at both MET-PET and FDG-PET: SUVmax and SUVmean of the most active lesion, background bone uptake (mean SUVmax of three vertebral bodies not focally involved) and tumour-to-background ratio (TBR) calculated as the ratio between SUVmax of the most active lesion and brain uptake (for MET-PET) or liver uptake at the right lobe (for FDG-PET). Mann-Whitney U-test was used to determine whether such PET-derived parameters significantly ($P<0.05$) reflected the presence of serum/urine mIg or BM involvement > 20%; bivariate non-parametric correlation (Spearman's ρ) was calculated between each PET-derived parameter and % plasma cell BM involvement, mIg, FLCs or %CD138 surface expression. **Results:** Seventeen patients (mean age 62y) were studied according to the aforementioned criteria. MET-PET recognized more focal lesions than FDG-PET (115 vs 24) with significantly ($P=0.012$) higher SUVmax, TBR and background bone uptake. MET-PET TBR was significantly higher in patients with presence of serum (median 4.51 interquartile range [IQR] 3.89-6.73 vs 2.58 IQR 2.16-4.43, $P=0.027$) or urine mIg (median 5.47 IQR 4.43-11.77 vs 3.83 IQR 2.49-4.74, $P=0.019$). MET-PET SUVmax, SUVmean and TBR were higher in patients with BM involvement > 10% (median 9.89 IQR 8.27-17.02 vs 5.31 IQR 4.76-7.43, $P=0.008$; median 5.46 IQR 3.77-10.83 vs 3.98 IQR 3.19-4.51, $P=0.027$; median 5.64 IQR 4.63-10.10 vs 3.24 IQR 2.31-3.93, $P=0.001$, respectively). FDG-PET derived parameters were not associated to serum/urine mIg or BM involvement > 20%. A significant correlation was found between MET-PET TBR and % plasma cell BM involvement ($ρ=0.75$), but not for FDG-PET TBR ($ρ=0.27$). **Conclusion:** Our study demonstrated that in MM patients at first disease staging MET-PET functional parameters (but not FDG-PET ones) reflect the underlying pathophysiology in terms of BM involvement and mIg production.

OP-346

Diagnostic performances of normalized FDG-PET parameters in predicting treatment response < progression-free survival after bone marrow transplantation in patients with multiple myeloma

D. Ripani[1], C. Caldarella[2], T. Za[3], D. Pizzuto[1], E. Rossi[3], V. De Stefano[3], A. Giordano[1]; [1]Institute of Nuclear Medicine, Università Cattolica del Sacro Cuore "A. Gemelli", Rome, ITALY, [2]Nuclear Medicine Unit and PET-CT Center, Policlinico "A. Gemelli", Rome, ITALY, [3]Hematology Service, Università Cattolica del Sacro Cuore "A. Gemelli", Rome, ITALY.

Background and Aim: Patients with multiple myeloma (MM) may benefit from induction chemotherapy (iChT) &lt bone marrow transplantation (BMT). FDG-PET is useful in early assessment of response to treatment &lt disease progression; several factors affect the reliability of semi-quantitative parameters in evaluating FDG uptake in lesions. Aims of our study were: to determine whether normalized semi-quantitative parameters may predict the response to treatment &lt disease progression; to determine whether such parameters could predict patients' progression-free survival. **Materials and Methods:** Patients undergoing iChT &lt BMT with baseline &lt after treatment FDG-PET were considered. Several parameters were obtained: SUVmax, SUVmean, SUVpeak, rPET &lt qPET of the most active lesion. rPET was calculated as lesion SUVmax/liver SUVmax (right lobe); qPET was calculated as lesion SUVpeak/liver SUVmean (right lobe). Baseline-to-post-treatment scan changes (Δ) were calculated for each parameter. Metabolic progression or metabolic response at follow-up FDG-PET scans were noted; time-to-metabolic-progression (TMP) was considered the interval from post-treatment scan to subsequent progression at follow-up FDG-PET. Mann-Whitney U-test was used to evaluate whether each functional parameter (baseline, post-treatment &lt Δ) was significantly ($P<0.05$) associated to metabolic progression or response. Kaplan-Meier survival curves assessed the TMP trend according to FDG-PET parameters; discriminant analysis was used to calculate a reliable cut-off for each parameter to find significant ($P<0.05$) differences between curves. **Results:** Thirty-eight patients were considered, 19 with metabolic progression during follow-up, 16 with metabolic response during follow-up (3 patients had stable disease). Significantly lower ΔrPET (median 0.06 [interquartile range (IQR) -0.22 - 0.34] vs 0.41 [IQR 0.16 - 1.13]; $P=0.023$) &lt ΔqPET (median 0.06 [IQR -0.24 - 0.45] vs 0.54 [IQR 0.15 - 1.09]; $P=0.030$) were found in patients with metabolic progression during follow-up. Significantly higher ΔrPET (median 0.41 [interquartile range (IQR) 0.17 - 1.07] vs 0.06 [IQR -0.22 - 0.48]; $P=0.023$) was found in patients with metabolic response during follow-up. According to Kaplan-Meier curves, higher post-treatment rPET &lt lower ΔrPET predicted a significantly lower TMP ($P=0.015$ and $P=0.001$, for post-treatment rPET &lt for ΔrPET respectively). Median TMP was 25 months in patients with post-treatment rPET > 1.02 &lt 21 months in patients with ΔrPET < 0.36; most patients with lower post-treatment rPET or higher ΔrPET than the cut-offs showed no metabolic progression at the end of follow-up. **Conclusions:** Our results show that normalized semi-quantitative parameters, particularly ΔrPET, may predict metabolic response or progression during follow-up &lt progression-free survival in patients with MM undergoing iChT &lt BMT.

OP-347

Diagnostic Value of ¹⁸F-FDG PET/CT in Chronic Graft Versus Host Disease (cGVHD)

C. Lasnon[1,2], N. Aide[3,4], J. Parienti[5], S. Chantepie[6]; [1]Nuclear Medicine Department, François Baclesse Centre, CAEN, FRANCE, [2]INSERM

U1086, Caen, FRANCE, ³Nuclear Medicine Department, University Hospital, CAEN, FRANCE, ⁴INSERM U1086 "ANTICIPE", Caen, FRANCE, ⁵Biostatistical Department, University Hospital, CAEN, FRANCE, ⁶Hematology Institute, University Hospital, CAEN, FRANCE.

Aim: Allogeneic stem cell transplantation (SCT) is a curative option in hematological malignancies. It results in a cGVHD in 30-70% of cases which is diagnosed by biopsies of affected organs and/or observation of clinical symptoms. This diagnosis is sometimes difficult and may be underestimated in patients with no obvious clinical signs. The improvement of cGVHD diagnosis could allow guiding the treatment after transplant and thus optimizing the outcome of allograft patients. We aimed to evaluate the diagnostic value of ¹⁸F-FDG PET/CT for cGVHD detection. **Materials and Methods:** Twenty patients treated by allogeneic SCT were prospectively included (*ClinicalTrials. gov Identifier: NCT02352064*). Whole-body ¹⁸F-FDG PET/CT were performed 4 to 6 weeks after discontinuation of immunosuppressive therapy. Images were reconstructed with PSF reconstruction optimized for diagnostic and for EARL-compliant quantification. PET/CT examinations were interpreted by two blinded nuclear physicians with a consensus reading in case of discrepancy. Location and SUV_{max} of abnormal uptakes were recorded and stratified according to a 5-point scale and finally each examination was classified as positive or negative. The gold standard was the clinical examinations based on NIH recommendations up to 3 months after ¹⁸F-FDG PET/CT (± biopsies). Sensitivity, specificity and positive and negative predictive values (PPV, NPV) were estimated. Mann-Whitney test was used to compare median SUV_{max} values. **Results:** Mean (SD) patient age was 49.9 (10.1) years and sex ratio (M:F) was 13:7. Patients had undergone allogeneic SCT for acute myeloid leukemia (55%), acute lymphoid leukemia (15%), myelodysplasia (10%) and other diseases (20%). The prevalence of cGVHD was 9/20 (45%). Before PET consensus readings, discrepancies between observers occurred in 4 patients (20%). Sensitivity and specificity of ¹⁸F-FDG PET/CT were 0.67 (95%IC: 0.31-0.91) and 0.82 (95%IC: 0.48-0.97), respectively. PPV, NPV were 0.75 (95%IC: 0.36-0.95), 0.75 (95%IC: 0.43-0.93), respectively. For both observers, there was no significant difference between median SUV_{max} value of pathological foci in cGVHD patients and median SUV_{max} value of benign lesions in disease free patients (P>0.05). Hypermetabolic lesions in cGVHD patients were localized in digestive tract (50%), ENT sphere (35%) and skin (15%) according to observer 1 and in digestive tract (40%), ENT sphere (33%), lymph nodes (13%), skin (7%) and other sites (7%) according to observer 2. **Conclusion:** ¹⁸F-FDG PET/CT based on visual assessment could be a promising tool together with clinical examinations and biopsies to help to diagnose cGVHD. Neither quantitative analysis nor whole-body scan appeared to be necessary.

OP-348
Ultrafast 8-min scan PET/MR protocol for diagnosis and follow-up of Lymphomas. Preliminary results

C. Albertti, G. Peña, E. A. Marino, P. Jaime; FUESMEN, Mendoza, ARGENTINA.

Purpose: The aim of this study is to evaluate a PET/MR protocol that reduces acquisition time to 8 minutes, minimizing image co-registration errors, as well as reducing both patient discomfort and accumulated effective dose. It is shown to keep and even to increase sensitivity and specificity levels, as compared to the PET/CT gold standard protocol in use at our facility. **Subjects & Methods:** Five patients with confirmed diagnosis of lymphoma were injected intravenously with 4.07 MBq/kg of FDG. After a 50 minute uptake period, a PET/MR scan was performed with an ultra-fast protocol of 1 min/bed (GE Signa PET/MR, Milwaukee, WI, USA). Simultaneously, MRAC sequence for attenuation correction, T1LAVA (Water, Fat, In Phase and Out Phase) in axial and coronal sequences were performed. Subsequently, 65 minutes after radiotracer administration, a PET/CT scan (GE Discovery STE) was performed with 3min/bed acquisition. Data were reconstructed with 2 iterations, 20 subsets, and scatter correction was applied in both methods. All studies were independently analyzed by 2 Nuclear Physicians, one of them also specialist in Radiological Diagnostic Imaging. Results: A total of 60 SUVmax quantifications in lesions with probable lymphoproliferative involvement and in hepatic, splenic and bone marrow parenchyma in both methods (PET/MR and PET/CT) were analyzed. 51 measurements on both sets were characterized as coincidental and 9 measures were discordant, which were only detected in PET/MR. In addition, a brain lesion and a better characterization of bone marrow lesions were found in three patients from the anatomical information of MR images, being unnoticed by the CT scan. Discussion: The first studies performed with ultrafast PET/MR protocol for diagnosis and/or follow-up of lymphomas, show similar sensitivity and specificity with less effective doses when compared to PET/CT protocols. Moreover, PET/MR provides additional findings which were undetected by PET/CT alone. The ultra-fast protocol of 8 minutes scan greatly contributes to patient comfort and cooperation. These promising results should be confirmed with a larger number of studies.

OP-349
Staging Patients with Hodgkin Lymphoma - Is Bone Marrow Biopsy Still Necessary in the Era of ¹⁸F-FDG PET?

C. Voltin¹, S. Stockter¹, C. Baues², M. Fuchs³, M. Dietlein¹, J. Mettler¹, A. Engert³,⁴, P. Borchmann³,⁴, A. Drzezga¹, C. Kobe¹; ¹Department of Nuclear Medicine, University Hospital of Cologne, Cologne, GERMANY, ²Department of Radiation Oncology, University Hospital of Cologne, Cologne, GERMANY, ³German Hodgkin Study Group (GHSG), University Hospital of Cologne, Cologne, GERMANY, ⁴Department of Internal Medicine I, University Hospital of Cologne, Cologne, GERMANY.

Introduction: Staging with 2-(¹⁸F)fluoro-2-deoxy-D-glucose (¹⁸F-FDG) positron emission tomography (PET) might be reliable to detect bone marrow (BM) involvement and advanced-stage disease in patients with Hodgkin lymphoma (HL). As ¹⁸F-FDG PET became a common procedure, BM biopsy may be omitted without impairment of the detection of advanced-stage disease. Therefore, the aim of this study was to assess the concordance

of ^{18}F-FDG PET and BM biopsy results in HL patients. **Methods**: The initial staging of all patients enrolled to the German Hodgkin Study Group (GHSG) trials HD16, HD17 and HD18 included a mandatory BM biopsy, while ^{18}F-FDG PET was a facultative procedure. We centrally reviewed all available baseline ^{18}F-FDG PET scans and categorized BM as showing focal involvement or not. All cases with diffusely increased BM uptake were documented but not interpreted as BM involvement. Additionally, we noted both the number of lesions and their localization. **Results**: A total of 832 patients who have been recruited into the above-mentioned GHSG studies until 31st December 2015 underwent a ^{18}F-FDG PET scan for staging which was assessed by the central review panel. 19 out of 20 cases with positive BM biopsy were identified by ^{18}F-FDG PET and 1 was documented to have diffusely increased BM uptake. Additional focal ^{18}F-FDG-avid BM lesions were detected in 110 patients who would have otherwise been considered negative by BM biopsy. A unifocal pattern was recorded in 43, a bifocal in 17, a trifocal in 11 and a multifocal (more than 3 lesions) in 58 cases. In addition, a diffusely increased BM uptake was noted in 152 patients. As compared to biopsy results, sensitivity, specificity, positive predictive value and negative predictive value of ^{18}F-FDG PET were found to be 95.0 % [95 % confidence interval (CI) 0.75, 1.00], 86.5 % (95 % CI 0.84, 0.89), 14.7 % (95 % CI 0.12, 0.17) and 99.9 % (95 % CI 0.99, 1.00), respectively. **Conclusion:** In our cohort, ^{18}F-FDG PET was able to detect the vast majority of cases with BM involvement according to biopsy results. Furthermore, it could identify a large number of additional cases suspicious for BM involvement who would have been considered negative by BM biopsy. This indicates that the actual incidence of BM involvement may be substantially underestimated by conventional BM biopsy. Given the high negative predictive value, baseline ^{18}F-FDG PET imaging can be safely used to exclude BM involvement in patients with HL.

FDG-PET/CT at the end of immuno-chemotherapy in Follicular Lymphoma: the prognostic role of the ratio between target lesion and liver SUVmax (rPET)

S. Annunziata[1], A. Cuccaro[2], M. C. Tisi[2], S. Hohaus[2], A. Giordano[1], V. Rufini[1]; [1]Institute of Nuclear Medicine, Università Cattolica del Sacro Cuore, Rome, ITALY, [2]Institute of Hematology, Università Cattolica del Sacro Cuore, Rome, ITALY.

Purpose: FDG-PET/CT at the end of immuno-chemotherapy (PI-PET) in patients with Follicular Lymphoma (FL) has been recently proposed as a prognostic tool, visually evaluated by International Harmonization Project criteria (IHP) or Deauville Score (DS). Nevertheless, some limitations of the published data on this topic recently emerged, such as the absence of clear advantages of PI-PET over clinical FL International Prognostic Index at diagnosis (FLIPI). The ratio between target lesion and liver SUVmax (rPET) was recently confirmed as a strong prognostic factor in Hodgkin Lymphoma, with diagnostic and methodological advantages over visual analysis. Aim of this study was to retrospectively investigate the prognostic role of rPET in patients with FL undergoing PI-PET. **Methods:** Eighty-nine patients with FL who underwent PI-PET were retrospectively evaluated. The receiver operating characteristic (ROC) approach was applied to identify the optimal cut-point of rPET with respect to events, to calculate accuracy values and to define the area under the curve (AUC). IHP was considered positive with FDG uptake higher than the local background or higher than mediastinal blood pool (for lesions smaller or greater than 2 cm, respectively); DS 4 and 5 were considered positive. Progression-free survivals at 5-years (PFS) according to different PI-PET results (IHP, DS, rPET) and FLIPI were evaluated, considering progression, lack of complete remission and relapse after treatment as adverse events. A sub-analysis for patients who continued maintenance therapy with Rituximab was performed. **Results**: The ROC analysis for rPET as predictor of progression showed an AUC of 0.75, with an optimal rPET cut-point of 0.98. Positive IHP were 21/89 (24%) and had lower PFS compared to patients with negative IHP (50% vs 87%, p=0.0001). Positive DS were 10/89 (11%) and had lower PFS compared to patients with negative DS (30% vs 84%, p<0.0001). Positive rPET were 13/89 (15%) and had a PFS of 31%, negative rPET patients of 91% (p<0.0001). PI-PET prognostic power increased in patients who continued maintenance therapy with Rituximab (n=52/89, 58%), with a PFS of 17% in positive DS and 100% in negative IHP. FLIPI was not predictive of relapse and progression (p=0.31). **Conclusions**: rPET is a prognostic factor in patients with FL who underwent PI-PET and could be useful to identify patients with FL at risk for relapse after immuno-chemotherapy. PI-PET seems to have a stronger prognostic power in patients submitted to maintenance therapy and seems to have an incremental power over FLIPI at diagnosis.

OP-351

Interim treatment response assessment in paediatric Hodgkin's lymphoma by using Deauville and delta SUVmax in FDG PET CT

K. Shaha, S. Shah, N. Purandare, A. Agrawal, A. Puranik, V. Rangarajan; TATA Memorial Hospital, Mumbai, INDIA.

Aim: To compare Deauville 5 point score (DS) and delta SUVmax response assessment criteria used for interpretation of the interim PET in paediatric Hodgkin lymphoma (HD). **Material and Methods:** This was institutional ethics committee approved retrospective observational study. 152 consecutive paediatric (< 18 years) patients with newly diagnosed HD from January 2011 to August 2013 were enrolled in study. All patients had undergone baseline and interim 18 F FDG PET/CT (PET). Interim PET was analysed using Deauville and Delta SUVmax. Variables used in univariate analysis were sex, anaemia, hypoalbuminaemia, leucocytosis, lymphopenia, ESR, LDH, bone marrow biopsy(BMB), splenic involvement, Ann arbour stage, early versus advanced stage, anatomical residual disease, DS and delta SUVmax. DS of 1, 2 and 3 were considered negative and 4 and 5 were considered negative. Delta SUVmax cut off was considered to be 66%. Kaplan Meir survival analysis was used to calculate overall survival (OS) and event free survival (EFS). Univariate variables with significant p value (<0.05) were used for multivariate survival

analysis using COX regression analysis by forward regression method. **Results:** Median follow up was 44 months. 19 out of 152 patients had events (relapse/progression). 4 patients died in the follow up period. In univariate analysis DS, delta SUVmax, anatomical residual disease, sex, lymphompenia, spleen, early vs advanced stage and Ann arbour stage showed statistically significant EFS. In multivariate analysis only DS was significant with p value 0.000 (HR-20.21) for EFS. For overall survival DS, delta SUVmax and lymphopenia were statistically significant in univariate analysis. However only delta SUVmax was statistically significant in multivariate analysis with p value of 0.01 (HR-19.64). EFS was (38 vs 68 months) (p value <0.000) and (37 vs 67 months) (p value 0.000) in interim PET positive vs negative patients according to DS and delta SUVmax respectively. OS was (62 vs 72 months) (p value <0.001), (60 vs 72 months) (p value 0.000) in interim PET positive vs negative patients according to DS and delta SUVmax respectively. **Conclusion:** Interim PET has strong correlation with survival and hence can be used as an independent prognostic factor in HD. Deauville criteria should be used for interpretation of interim PET in HD.

OP-352

B-cell lymphoma radioimmunotherapy: effect of co-infusion of cold and radiolabelled antibody on absorbed dose to healthy tissues and tumours, a preclinical study in dogs

F. Morio[1,2], C. Ibisch[1,2], F. Nguyen[1,3], M. Berthaud[2], J. Abadie[1,3], A. Vidal[4], M. Bourgeois[4,2,5], K. Bernardeau[6], S. Becavin[1], M. Roussel[1], L. Ferrer[2,7], C. Bodet-Milin[2,5], N. Chouin[1,2], F. Davodeau[2]; [1]AMaROC, Oniris (Nantes Atlantic College of Veterinary Medicine, Food Science and Engineering), NANTES, FRANCE, [2]Team 13 "Nuclear oncology research", CRCINA, INSERM UMR1232, Université d'Angers, Université de Nantes, Nantes, FRANCE, [3]Team 8 "Stress Adaptation and Tumor Escape", CRCINA, INSERM UMR 1232, Université d'Angers, Université de Nantes, Nantes, FRANCE, [4]Radiopharmacy Department, ARRONAX Cyclotron, Saint-Herblain, FRANCE, [5]Departement of Nuclear Medicine, University Hospital, Nantes, FRANCE, [6]Recombinant Protein Core Facility of The University of Nantes, NANTES, FRANCE, [7]Institut de Cancérologie de l'Ouest, Medical Physics Department, Saint-Herblain, FRANCE.

Purpose/Introduction: Our research team, specialized in comparative oncology, developed molecular tools to address clinically relevant questions in immuno-SPECT and radioimmunotherapy of the B-cell lymphoma. This study aimed at demonstrating the feasibility and the relevance of anti-CD22 immuno-scintigraphy in dogs. Our second objective was to evaluate the interest of the systematically co-injection of labelled-unlabelled CD22 antibodies in human RIT by comparing the pharmacokinetics in dogs of an anti-CD22 antibody, radiolabelled with indium-111, with or without co-injection of the same unlabelled antibody. Subjects and methods: Six dogs (4 healthy dogs and 2 dogs bearing CD22+ B-cell lymphoma) were injected with a monoclonal murine anti-canine CD22 antibody radiolabelled with indium-111 in order to derive the antibody pharmacokinetics by SPECT imaging. Two healthy dogs and one lymphoma dog

were co-injected with a dose of unlabelled antibody (270 μg of radiolabelled antibody + 17.4mg of cold antibody), whereas the other 3 dogs received only the radiolabelled antibody (750μg). SPECT/CT images were acquired at 3 to 5 time-points following the administration (from 1h to 144h). Blood samples were also collected at 5 time-points after injection. Major organs and visible tumour lesions were delineated on CT images and the activity uptake was derived from SPECT images. Mean absorbed doses in the organs/lesions were calculated for all the dogs. **Results:** In healthy animals, the antibody residence time in blood was lower for animals injected with radiolabelled antibody only (13±1h vs 31±2h). Activity uptake in the spleen was significantly higher for dogs, which received only the radiolabelled antibody, leading to a three-fold increase in the mean absorbed dose to spleen (8.3±0.8 mGy/MBq vs 2.5±0.5 mGy/MBq). Cumulated activity within bone marrow was also 2.5 to 3 times higher in these dogs. Mean absorbed doses in other organs (kidneys, lungs, liver) were similar with or without cold antibody co-injection. In the two CD22+ B-cell lymphoma-bearing dogs, which had spleens infiltrated with disease, as assessed by ultrasound imaging, antibody uptake in the spleen was higher than in the healthy dogs indicating a specific targeting of the lymphoma cells. Infiltrated lymph nodes were also visible on SPECT imaging for both dogs. Discussion/conclusion: In the context of B-cell lymphoma RIT, with anti-CD22 antibody, co-injection with cold antibody allows for a longer residence time in blood and a limited uptake in spleen and bone marrow. Further studies should establish if these findings represent always a therapeutic advantage for patients, in regards to tumour uptake.

Cardiovascular System: Cardiac Sarcoidosis & Amyloidosis

OP-353

Prevalence of myocardial uptake in bone scan in the elderly population

L. Mohamed Salem, Sr., R. Reyes Marles, M. Godoy Bravo, J. Sánchez Serna, M. Castellon Sanchez, F. Nicolas Ruiz, L. Frutos Esteban, J. Navarro Ferenandez, I. Sime Loayza, M. Perez Martinez, D. Pascual Figal, M. Claver Valderas; Hospital Clínico Universitario Virgen de la Arrixaca, Murcia, SPAIN.

Introduction: Cardiac amyloidosis is a common cause of heart failure in the elderly, around 25% of patients over the age of 80 years have Amyloidosis TTR-wild Type in the heart autopsy studies, which suggests its potential contribution to the development of heart failure with preserved ejection fraction, nevertheless, the real prevalence of the disease is still unknown. According to late scientific evidence from large multicentre trial, myocardial uptake of bone tracers has a high specificity and sensitivity for the diagnosis of cardiac transthyretin amyloidosis. Purpose To determine the prevalence of myocardial uptake in bone scan in the elderly population, without previous clinical

suspicion of cardiac amyloidosis. **Subjects and Methods:** We revise retrospectively 1562 bone scans that were performed in our Department between 2010 and 2017, to elderly patients of 80 years and over, using conventional bone tracers Tc99m-HDP, Tc99m-DPD and Tc99m-HMDP, with usual bone scan clinical indications (prostate and breast cancer staging etc). Patients with clinical suspicion of cardiac amiloidosis, were excluded from the analysis. We classified the myocardial tracer uptake into 3 grades, taking as a reference the adjacent rib uptake; grade 1 is less than the rib, grade 2 equal to the rib and grade 3 more than the rib uptake **Results:** There was myocardial tracer uptake in 124 of 1562 revised bone scans (7.92%). Grade 1: 41 patients (33%), grade 2: 42 patients (34%), grade 3: 41 patients (33%). 82 patients had grade 2 and 3, which is 66% of positive patients and 5,25% of all revised bone scans, which indicates with high specificity and sensitivity, according to current evidence from literature, the presence of cardiac TTR Amyloidosis. Given that the myocardial take is highly suggestive of cardiac amyloidosis, our study indicated a prevalence of cardiac amyloidosis of almost 8%, which suggests its potential contribution to heart failure in the elderly. **Conclusion:** The prevalence of myocardial uptake in bone scan in the elderly is 7,92%. The prevalence of Transthyretin Cardiac Amyloidosis in the elderly is 5,25%. These results indicate a high prevalence of cardiac amyloidosis in the elderly as a cause of heart failure in this population.

OP-354

Prognostic impact of cardiac FDG-PET/CT using quantitative analysis in patients with cardiac sarcoidosis

T. Ando, Y. Fukushima, S. Kumita, H. Hashimoto, Y. Sugihara; Nippon Medical School, Tokyo, JAPAN.

Objective: Cardiac sarcoidosis is a potentially fatal condition in patients with sarcoidosis and ^{18}F-FDG-PET/CT can evaluate the severity of inflammation activity in cardiac sarcoidosis lesions. However, the relationships between cardiac FDG accumulation parameters and prognosis has not been sufficiently examined. The purpose of this study was to estimate the prognostic performance of cardiac FDG-PET/CT using low-carbohydrate diet and accumulation quantification software. **Materials and Methods:** A total of 20 consecutive cardiac sarcoidosis patients (6 men and 14 women, 62 ± 12 y) who underwent FDG-PET/CT using low-carbohydrate diet over 24 h (glucose intake < 10 g) were included in this study. FDG-PET images were acquired 60 min and 120 min after the administration of FDG 2.88 MBq/kg. Using accumulation quantification software GI PET, volumes of interest were automatically drawn in the myocardium setting the threshold standardized uptake value (SUV) as 1.40. Metabolic volume (MV) and total lesion glycolysis (TLG) in each lesion and entire-lesion overall values of these parameters were measured. In order to evaluate the clinical importance of overall TLG (OTLG), all patients were divided into two groups based on the value of OTLG using a receiver-operating-curve analysis. All patients were followed up over 2.1 (0.95-3.28) years from the initial FDG-PET/CT and observed for the occurrence of major adverse cardiac events, defined as cardiac death, hospitalization

due to deterioration of heart failure, development of ventricular tachycardia, and requirement of steroid therapy. **Results:** In all 20 patients, SUVmax was 3.35 (1.98-3.88), overall MV was 20 (6-132) cm^3, and OTLG was 32 (10-262). Among them, 9 were assigned to the high OTLG group while 11 were assigned to the low OTLG group. OTLG was 287 (102-479) in the high group and 11 (5-28) in the low group. Of the 20 patients, 5 (25%) experienced MACE during the follow up period. The proportion of patients that developed MACE was significantly higher in the high OTLG group than in the low OTLG group (5 of 9 versus 0 of 11 patients, p =0.008). Multivariate logistic regression analysis demonstrated that OTLG was the sole independent prognostic factor for MACE (p = 0.04). **Conclusions:** The severity of cardiac sarcoidosis activity was estimated by calculating SUVmax, overall MV, and OTLG. FDG-PET/CT using low-carbohydrate diet over 24 h as well as accumulation quantification software may have a high prognostic value for the occurrence of MACE in patients with cardiac sarcoidosis.

OP-355

Novel approach for myocardial sarcoidosis diagnosis using Ga-68-DOTATATE PET/CT: Reference values in a normal population

M. Jreige, M. Nicod Lalonde, A. van der Gucht, N. Schaefer, J. O. Prior; Centre Hospitalier Universitaire Vaudois (CHUV), LAUSANNE, SWITZERLAND.

Purpose: The emerging application of PET/CT using radiolabeled somatostatin receptor (SSTR) ligands such as Ga-68-DOTATATE for the investigation of myocardial inflammation seems to be a valuable alternative to FDG PET/CT in the emergency settings without the need for a lengthy patient preparation. This study aimed to report normal reference values of cardiac metabolic uptake of Ga-68-DOTATATE PET/CT to provide a basis for comparison for pathological cases. **Materials and Methods:** We retrospectively assessed Ga-68-DOTATATE PET/CT uptake in different cardiac regions in a population of 18 patients addressed for tumoral investigation without known myocardial inflammation or cardiac symptoms (M:F=10:8; mean age 54±14 years). Ga-68-DOTATATE PET/CT were analyzed to define SUVmax and SUVmean values in both the basal and apical myocardial regions of the left and right ventricle, as well as in the septum. We calculated the ratio of the uptake in the the basal and apical myocardial regions of the left ventricle to the intra-ventricular blood pool uptake. Results of two pathologic cases were also reported as example for comparison. **Results:** In the normal population, Ga-68-DOTATATE uptake (SUVmax/SUVmean in g/mL) was of 1.9±0.5g/mL (range 1.3-3.7)/1.1±0.3 (0.8-2.2) in basal LV, 1.9±0.5 (1.3-3.7)/1.1±0.3 (0.7-2) in apical LV, 1.7±0.7 (1-3.9) and 1± 0.5 (0.6-2.6) in basal RV, 1.6±0.5 (1-3.1)/0.9±0.3 (0.6-1.9) in apical RV, and 1.8±0.7 (1.1-3.8)/1.1±0.4 (0.6-2.1) in the septum. Mean ratios of SUVmax/SUVmean to blood pool uptake were: 1.5±0.3/1.4±0.3g/mL in basal LV, 1.4±0.2/1.3±0.3g/mL in apical LV, 1.2±0.1/1.1±0.1g/mL in basal RV, and 1.2±0.1/1.1±0.2g/mL in apical RV. As comparison, the mean ratios of SUVmax/SUVmean to blood pool uptake in 2 patients with sarcoidosis

were 2.7/2.6 in basal LV and 1.9/1.7 in apical LV with a very clear visualization on PET/CT. **Conclusions:** This study reports normal Ga-68-DOTATATE cardiac uptake in apical, basal and septal regions of the normal myocardium and provides potential normal ratios of myocardial uptake to blood pool. These reference values provide a a basis for this novel diagnosis tool for cardiac inflammation with evident differences in SUV measurements and visual assessment.

OP-356
[18F]-Florbetaben-PET/CT for Imaging of cardiac amyloidosis

M. Kircher, J. Brumberg, T. Reiter, S. Ihne, S. Knop, K. Kortüm, G. Ertl, A. Buck, W. Bauer, C. Lapa; Uniklinikum Würzburg, Würzburg, GERMANY.

Purpose: The aim of this study was to investigate the performance of [18F]florbetaben-PET/CT in comparison to CMR and scintigraphy. IntroductionCardiac amyloidosis is a rare form of restrictive cardiomyopathy which can arise from different causative conditions. Since echocardiography as the initial screening test suffers from limited specificity and myocardial biopsies are prone to sampling error, other imaging modalities including cardiac magnetic resonance (CMR) or scintigraphy with radio-labelled bisphosphonates are routinely used. Recently, positron emission tomography/computed tomography (PET/CT) emerged as a new alternative. **Subjects & Methods**: A total of 20 patients with suspicion of cardiac amyloidosis underwent [18F]florbetaben-PET/CT, CMR, scintigraphy as well as echocardiography. Qualitative and quantitative assessment of [18F]florbetaben-PET/CT was performed and compared to other imaging results. Additionally, in 2 patients a follow-up study after treatment initiation was performed after 6 and 11 weeks, respectively. **Results:** [18F]florbetaben-PET/CT was visually positive in all patients with cardiac amyloidosis independently from amyloidosis type. Of note, in two PET-negative patients, cardiac involvement could be ruled out by subsequent biopsy. PET results could be confirmed by other imaging modalities. **Conclusions/Discussion:** [18F]florbetaben-PET/CT can accurately identify cardiac amyloidosis involvement irrespective of the underlying etiology. Imaging corresponded well with CMR results. It might also prove a valuable tool in therapy monitoring.

OP-357
[18F]-Florbetaben PET/CT in cardiac amyloidosis: results from the FLORAMICAR study

D. Genovesi, G. Vergaro, A. Giorgetti, M. Emdin, E. Volpi, S. Alduini, A. Kusch, B. Favilli, S. Fucci, P. Marzullo; Fondazione CNR-Regione Toscana "Gabriele Monasterio", Pisa, ITALY.

Aim: The hypothesis is that PET/CT tracers for cerebral amyloid also bind to extracerebral amyloid deposits. The study has been proposed to evaluate and quantify the uptake of [18F]-Florbetaben in the heart of patients with cardiac amyloidosis. **Materials and Methods:** 12 patients with cardiac amyloidosis were enrolled. 6 patients had transtiretine-related amyloidosis (ATTR) while 6 patients had light chains-related amyloidosis (AL). Each patient underwent to a dynamic cardiac PET/CT scan during the injection of 300 Mbq of [18F]-Florbetaben followed by whole-body scan, brain scan and delay cardiac scan. **Results:** All patient showed a cardiac uptake of the tracer. In the AL group there was an early uptake rising to a maximum between 5 and 10 minutes after the injection and a "plateau" profile until the end of the dynamic acquisition; in the ATTR group there was the same early uptake followed by a rapid wash-out. In the first 15 minutes the median of cardiac SUV was 5,08 (range 2,88 - 8,22) in AL and 2,30 (range 2,05 - 5,42) in ATTR (P = 0,11), while in the following 50 minutes, the values were 3,73 (range 2,42 - 6,99) in AL and 1,15 (range 0,95 - 1,70) in ATTR (P = 0,02). The 15 minutes target to background ratio (TBR) was 4,14 (range 1,78 - 5,28) for AL and 2,04 (range 1,71 - 2,21) for ATTR (P = 0,20); the 50 minutes TBR was 2.58 (range 1,84 - 6,48) for AL and 1,03 (range 0,55 - 1,17) for ATTR (P = 0,02). Late cardiac scans confirmed these data showing an high cardiac uptake in the AL group and no cardiac uptake in the ATTR group. 2 ATTR patients showed a diffuse brain uptake and one of these showed also a diffuse bone marrow uptake, while 4 AL patients showed extracardiac uptake (tongue, bone marrow and lungs). **Conclusions:** [18F]-Florbetaben showed a significant uptake in the heart of patients with cardiac amyloidosis. In patient with AL the dynamic uptake shows a rapid wash-in without significant wash-out; in patients with ATTR there is a rapid wash-in followed by a rapid wash-out without significant cardiac uptake in the late cardiac scan. Brain uptake in ATTR patients suggests that brain involvement in the context of a systemic amyloidosis could not be due to the same type of amyloid deposits which involve other organs like the heart or the bone-marrow.

OP-358
Imaging amyloidosis patients with 18F Florbetapir PET - incidence and significance of non-cardiac soft tissue uptake

*J. Page[1,2], **T. Wagner**[2], M. Burniston[2], J. Ross[1,2], A. Skillen[2], D. McCool[2], T. Lane[1], R. Manwani[1], P. Hawkins[1], A. Wechalekar[1]; [1]National Amyloidosis Centre, London, UNITED KINGDOM, [2]Royal Free London NHS Foundation Trust, London, UNITED KINGDOM.*

Purpose: Amyloidosis is a rare but serious disease characterised by infiltration of abnormal protein deposits in tissues and organs throughout the body. ^{123}I-SAP (serum amyloid P) is used to image amyloid deposits in the liver, spleen and kidneys, but is only available in two centres worldwide and has low sensitivity for detecting amyloid in other organs, including the heart. As part of a study to assess the diagnostic value of ^{18}F-florbetapir in cardiac amyloidosis, we also identified other areas of soft tissue uptake and correlated these findings with ^{123}I SAP scan results. **Method:** 16 patients (14 AL, 2 ATTR) underwent dynamic cardiac PET imaging for 60 minutes following intravenous administration of 370MBq ^{18}F-florbetapir. This was then followed by a half-body PET-CT. Half-body images were assessed for areas of increased tracer accumulation and SUV_{max} for these areas was

measured. A spherical VOI was placed in the spleen and the descending aorta on the dynamic images and a spleen retention index (SRI) was calculated as the mean SUV from 10-30 minutes divided by the integral of the aorta SUV 0-20 minutes post-injection. **Results:** In the 16 patients imaged to date, uptake was seen in many different areas in which amyloid deposits are known to form (numbers of patients, range of SUV_{max}): spleen (6, 4.2-10.2), lungs (3, 6.8-37.0), fat (11, 1.6-4.3) tongue (8, 2.8-5.0), kidney (1, 4.1) and stomach wall (5, 3.6-8.6). ^{18}F-florbetapir uptake in the spleen on the half-body images was concordant with ^{123}I-SAP imaging in 13/16 patients. Taking a cut-off value of 0.03 the SRI was concordant with ^{123}I-SAP imaging in 15/16 patients. **Conclusion:** ^{18}F-florbetapir looks to be a promising, widely available PET tracer that enables the imaging of amyloid deposits in organs such as the lungs which cannot be assessed using existing imaging techniques and the spleen which can only otherwise be imaged using ^{123}I-SAP which is not widely available. Further work is needed to assess diagnostic and prognostic value as there have been very few studies yet reported.

OP-359

Cardiac amyloid imaging with [18]F Florbetapir PET - initial results from a UK study

J. Page[1,2], T. Wagner[2], M. Burniston[2], J. Ross[1], A. Skillen[2], D. McCool[2], T. Lane[1], R. Manwani[1], M. Fontanna[1], P. Hawkins[1], A. Wechalekar[1]; [1]National Amyloidosis Centre, London, UNITED KINGDOM, [2]Royal Free London NHS Foundation Trust, London, UNITED KINGDOM.

Purpose: Cardiac amyloidosis (CA) is a rare but serious disease characterised by infiltration of amyloid fibrils throughout the heart. Recently, a multi-centre study (Gilmore J. 2016, 133:2404-2412 Circulation) demonstrated the utility of ^{99m}Tc-labelled 3,3-diphosphono-1,2-propanodicarboxylic acid (DPD) in diagnosis of cardiac transthyretin amyloidosis (ATTR), but the tracer has poor sensitivity in systemic (AL) amyloidosis. Several groups have investigated brain amyloid tracers in CA patients, with promising results (Catafau A. 2015, 3:39-55 Clin Transl Imaging). **Method:** 16 patients (14 AL, 2 ATTR) underwent dynamic cardiac PET imaging for 60 minutes following intravenous administration of 370MBq ^{18}F-florbetapir. A spherical volume of interest of 1cm diameter was placed in the left ventricle (LV) chamber and the LV myocardium was manually outlined. The heart retention index (HRI) was calculated as the mean LV myocardial SUV from 10-30 minutes divided by the integral of the blood pool SUV 0-20 minutes post-injection. **Results:** Myocardial uptake of ^{18}F-florbetapir was seen in all patients. The median HRI was 0.14, (IQR=0.08-0.18). Mean HRI was lower in the ATTR patients (n=2, mean=0.06), as reported elsewhere (Dorbala S. 2014, 41:1652-1662 Eur J Nucl Med Mol Imaging). High HRI values were seen in treatment-naïve patients (n=2, mean=0.16). **Conclusion:** Our cohort confirmed 18F-florbetapir as a promising tracer for imaging cardiac amyloidosis. Median HRI in our patients is higher than others reported in the literature. This may be due to studying patients close to initial diagnosis. Further work is required to establish its role in diagnosis and monitoring of treatment.

OP-360

Cardiac FDG-PET/CT in systemic sclerosis

Z. Besenyi[1], G. Ágoston[2], R. Hemelein[3], A. Bakos[1], L. Kovács[3], A. Varga[2], L. Pávics[1]; [1]Department of Nuclear Medicine University of Szeged, Szeged, HUNGARY, [2]Department of Family Medicine University of Szeged, Szeged, HUNGARY, [3]Department of Rheumatology University of Szeged, Szeged, HUNGARY.

Aim: Systemic sclerosis (SSc) is a rare systemic connective tissue disease characterized by complex pathogenesis and multi organ involvement. Cardiac manifestation is a common complication in connective tissue diseases particularly in systemic sclerosis (SSc). In SSc the immuno-inflammatory damage leads to myocardial fibrosis and consequent myocardial dysfunction. Clinically evident heart involvement appears as a bad prognostic factor, responsible for up to 30 % of SSc-related mortality. 18F-FDG PET/CT plays an increasing role in the diagnostics of inflammatory disorders with myocardial manifestation. The aim of this study was to assess the diagnostic utility of cardiac 18F-FDG PET/CT in patients with SSc, and to evaluate simultaneously results of 2Dimensional Speckle Tracking Echocardiography (STE). **Materials and Methods:** 19 patients with systemic sclerosis (age: 57,3±10, 18 female, 1 male) where enrolled in the prospective study. After high-fat, high-protein, low carbohydrate - diet (previous 24 hours) and extended fasting (6 hours) cardiac 18F-FDG-PET/CT acquisition was performed in 2D mode and short-whole-body in 3D mode. Within 24 hours all patients underwent comprehensive echocardiography focusing on left ventricular myocardial mechanics applying STE. The recommended 17 segment model was used to assess the 18F-FDG activity and for the calculation of myocardial strain as well. On 18F-FDG PET/CT the segmental myocardial 18-FDG uptake in kBq/cc by PMOD software was calculated. The strain values were measured offline by speckle tracking EchoPAC software. **Results:** After diatery modification (mean 32,5±3,14 hours) and extended fasting (mean 18,72±5,52 hours) the mean blood glucose level of patients were 4,57±1,19 mmol/l. In 14 patients the cardiac uptake was near equal or lower than blood-pool activity. Visually there was no myocardial activity, and the muscular interventricular septum appeared "cold". In five patients (5/19) showed significantly increased 18F-FDG uptake (18,6±6,8 kBq/cc vs. 7,77±3,4 kBq/cc, p<0,01) in the myocardium. In patients with 18F-FDG increased uptake, measured global left ventricular longitudinal strain values (19,4±2,7% vs. 13,4±8%, p<0,01) were decreased. There was a negative correlation between myocardial strain and FDG uptake (p<0,05, r=-0,54). **Conclusion:** 18F-FDG PET/CT is a promising imaging tool to detect active myocardial inflammation of systemic sclerosis. In the active condition of the myocardial involvement STE provides a simple, non-invasive modality to detect metabolic activity related subtle mechanical changes in myocardium.

Neurosciences: Imaging Neurodegeneration in Alzheimer's Disease by TAU and FDG Imaging

OP-361

Flortaucipir perfusion PET is a suitable replacement for FDG PET in patients with neurodegenerative diseases

J. Hammes[1], I. Leuwer[1], G. N. Bischof[1,2], A. Drzezga[1], T. van Eimeren[1,2,3];
[1]Clinic of Nuclear Medicine, University Hospital Cologne, Cologne, GERMANY, [2]INM-3, Research Center Jülich, Jülich, GERMANY, [3]Clinic of Neurology, University Hospital Cologne, Cologne, GERMANY.

Aim: Cerebral glucose metabolism measured with FDG-PET is a well established marker of regional distribution and extent of neuronal cell loss in patients with neurodegenerative diseases such as Alzheimer's disease frontotemporal lobar degeneration or atypical Parkinson syndromes. Flortaucipir PET as an in vivo marker of hyperphosphorylated and misfolded Tau-protein aggregations as they occur in these diseases is currently under evaluation and shows promising results. In this study we assess the feasibility of early Flortaucipir PET acquisitions as a marker of cerebral perfusion and as possible replacement for an additional FDG-PET examination. **Methods:** 20 patients with suspected neurodegeneration underwent Flortaucipir and FDG PET imaging. Scans were performed on a SIEMENS Biograph mCT PET/CT. Ten one-minute timeframes were acquired directly after the application of 200 MBq Flortaucipir. FDG-PET images were acquired on a different date according to standard clinical protocol. Flortaucipir timeframes were coregistered to the individual FDG-scan and normalized to MNI space using SPM 12. Voxel-wise intermodal correlations were calculated on within-subject level for every possible time-window. The optimal acquisition time was determined by identifying the window with highest pooled within-subject correlation. Z-transformed deviation maps (ZMs) and stereotactic surface projections (SSPs) were created from both FDG and early Flortaucipir images using a standard FDG-norm cohort. **Results:** Visually the regional patterns and the extent of perfusion deficits in early Flortaucipir PET were highly comparable to the metabolic deficits in FDG-PET. Best results were observed in a time window from 60-360 seconds after application of the tracer with a pooled within-subject correlation coefficients of r=0.86. Region wise analysis revealed that correlation strength ranged from r=0.96 (subcortical grey matter) to r=0.83 (frontal lobe). ZMs and SSPs of early Flortaucipir and FDG PET images were also highly similar. **Conclusion:** Early Flortaucipir PET is a good biomarker to assess extent and regional distribution of neuronal cell loss in neurodegenerative diseases. By routinely replacing FDG PET by early Flortaucipir imaging, radiation exposure and complexity of the diagnostic workup could be reduced significantly.

OP-362

The impact of education on the association between tau deposits and cognition in Mild Cognitive Impairment

*S. Trombella[1], G. B. Frisoni[2], **V. G. Garibotto**[2]; [1]Geneva University, Geneva, SWITZERLAND, [2]Geneva University and Geneva University Hospital, Geneva, SWITZERLAND.*

Aim: Years of education (YE) is a well established proxy of the reserve capacity of the brain, modulating the association between the severity of neurodegeneration and cognition in Alzheimer's disease (AD). Aim of this study was to evaluate the presence of a correlation between YE and tau deposition, as measured by 18F-AV1451 PET, in a group of amyloid positive subjects with mild cognitive impairment (MCI). **Materials and Methods:** Data were obtained from an ongoing cohort study in our Institution and from the Alzheimer's Disease Neuroimaging Initiative (ADNI) database (www.loni.ucla.edu/ADNI). 128 patients received tau-PET imaging using 18F-AV-1451, amyloid-PET imaging using 18F-Florbetapir and 3D T1 MP-RAGE MRI imaging. For this study, we included subjects with a clinical diagnosis of MCI and amyloid positivity at PET imaging (i.e. cortical SUVR higher than 1.11). 36 subjects (23/13 males/females, mean age of 76 ± 7.9, mean Mental State Examination score -MMSE- of 25.8 ± 3.8, mean YE 15.7 ± 3.2) fulfilled the inclusion criteria. Image processing was performed in SPM 12 (Function Image Laboratory, Wellcome Department of Cognitive Neurology, London, UK) with the following steps: 18-AV1451 PET images were co-registered to the subject's MP-RAGE image, normalized using the deformation matrix derived by the segmentation of each MP-RAGE image, and subsequently smoothed using an 8 mm isotropic Gaussian kernel. SUVR parametric images were calculated dividing each voxel counts by the mean cerebellar crus counts. We used two multiple linear regression analyses to evaluate the correlation between the degree of cognitive impairment (expressed by the MMSE) or YE and tau deposition, correcting for the effect of age, imaging protocol (ADNI or Geneva) and YE or MMSE. Findings meeting a height threshold of p < 0.005, uncorrected, were considered significant. **Results:** As expected, a significant negative correlation between tau binding and MMSE score was retrieved in the temporal, posterior cingulate and precuneus and frontal cortex, bilaterally, stronger on the left hemisphere. No significant positive correlation was found. For education, a significant positive correlation was found in the left posterior cingulate cortex. No significant negative correlation was found. **Conclusion:** A positive correlation between higher tau deposition and YE in amyloid positive MCI subjects was shown in the left posterior cingulate cortex, suggesting that reserve associated with education compensates for neurodegeneration in this region.

OP-363

Parametric imaging of tau load in Alzheimer's patients and controls using Flortaucipir

S. S. V. Golla**[1], E. Wolters[1,2], T. Timmers[1,2], R. Ossenkoppele[1,2], C. Groot[1], S. Verfaillie[2], P. Scheltens[2], W. M. van der Flier[2,3], L. Schwarte[4], M. A. Mintun[5], M. Devous[5], R. C. Schuit[1], A. D. Windhorst[1], A. A. Lammertsma[1], R. Boellaard[1,6], B. N. M. van Berckel[1], M. Yaqub[1]; [1]Department of Radiology & Nuclear Medicine, VU University Medical Center, Amsterdam, NETHERLANDS, [2]Alzheimer Center & Department of Neurology, VU University Medical Center, Amsterdam, NETHERLANDS, [3]Department of Epidemiology & Biostatistics, VU University Medical Center, Amsterdam, NETHERLANDS, [4]Department of Anaesthesiology, VU University Medical Center, Amsterdam, NETHERLANDS, [5]Avid Radiopharmaceuticals, Inc., Philadelphia, PA, UNITED STATES OF AMERICA, [6]Department of

Nuclear Medicine & Molecular Imaging, University of Groningen, University Medical Center Groningen, Groningen, NETHERLANDS.

Background: Flortaucipir ([[18F]AV1451) is a promising positron emission tomography (PET) tau tracer used to visualize *in vivo* tau binding in Alzheimer's disease (AD). Recently, several [18F] AV1451 studies have been published identifying the optimal tracer kinetic model to perform a full quantitative analysis of the PET data. The purpose of the present study was to evaluate the performance of several parametric methods, as well as standardised uptake values ratios (SUVr), to obtain quantitatively accurate parametric images of [18F]AV1451. **Methods:** Dynamic PET scans of 130 minutes duration, including arterial sampling, were performed in 5 AD patients and 5 controls (C). Parametric images were generated using different linearization and basis function approaches. Plasma input based Logan and Spectral Analysis (SA) were used to generate volume of distribution (V_T) images. Several reference tissue based approaches such as reference Logan (RLogan), the multilinear reference tissue models (MRTM), receptor parametric mapping (RPM), and simplified reference tissue model 2 (SRTM2) were used to obtain binding potential (BP_{ND}) images. Regional BP_{ND} and V_T values obtained from the parametric images were compared to respective values derived from reversible two tissue compartment model (2T4k_V_B). Performance of the SUV_r was assessed by comparing the values to the distribution volume ratio (DVR) and SRTM derived BP_{ND} estimates obtained using non-linear regression (NLR). **Results:** Plasma input Logan ($r^2=0.96$; slope=0.78) and SA ($r^2=0.97$; slope=0.94) estimated V_T well. RLogan ($r^2=0.93$; slope=0.77), RPM ($r^2=0.96$; slope=0.97) and SRTM2 ($r^2=0.96$; slope=0.93) correlated well with NLR estimated DVR. Regional R_1 values extracted from RPM ($r^2=0.97$; slope=0.99) and SRTM ($r^2=0.94$; slope=0.99) correlated well with the R_1 NLR estimates. Although SUVr obtained using 80-100 min scan duration correlated well with the DVR ($r^2=0.93$; slope=1.07) and SRTM BP_{ND} ($r^2=0.84$; slope=0.95), bias and precision of SUVr depended on uptake time and subject group (or underlying specific binding level). **Conclusions:** RLogan and Logan correlated well but with an underestimation when compared to respective NLR estimates. Parametric images obtained using RPM and SA seems to provide accurate parametric BP_{ND} and V_T images, respectively, and are the recommended methods for voxel level parametric kinetic analysis. Individual SUVr values appear biased when compared to DVRs and that bias varies at different uptake times and DVR values. While preliminary, this bias suggests that SUVr should be used with caution, particularly in longitudinal studies when changes in specific binding are expected.

OP-364

Association between tau deposition, amyloid-β, age and memory performance in cognitively normal subjects: influence of partial volume correction

I. Sonni[1], A. Maaß[2], S. N. Lockhart[2], S. M. Landau[2], S. L. Baker[1], W. J. Jagust[1,2]; [1]Lawrence Berkeley National Laboratory, Berkeley, CA, UNITED STATES OF AMERICA, [2]Helen Wills Neuroscience Institute, University of California, Berkeley, Berkeley, CA, UNITED STATES OF AMERICA.

Aim: We sought to investigate the association between [18F]-AV-1451 tau PET tracer uptake and age, global brain beta-amyloid, and memory performance, and the effect of partial volume correction (PVC) among cognitively normal young, middle-aged and older adults. **Materials and Methods:** We included 86 cognitively normal subjects (6 young, 6 middle-aged, and 74 older adults, aged 22.8±2.6, 53±6.4 and 77.1±5.9 y, respectively). All subjects underwent a [18F]-AV-1451 tau PET, neuropsychological testing including a measure of verbal (California Verbal Learning Test - CVLT) and visual recall, and structural 1.5T MRI (T1-weighted, MPRAGE). 76 subjects also received [11C]-PiB PET. FreeSurfer was used to segment MRIs to obtain the regions of interest (ROIs). [18F]-AV-1451 SUVR images were created based on mean uptake over 80-100 min post-injection and normalized by mean inferior cerebellar gray matter. Distribution volume ratios (DVRs) for PiB images were generated with Logan graphical analysis on PiB frames corresponding to 35-90 min post-injection using a cerebellar gray matter reference region. The PiB index (weighted-mean DVR across cortical regions) was used as a measure of global cortical PiB uptake. [18F]-AV-1451 signal was collapsed into ROIs that represented pathological Braak stages, resulting in three composite ROIs (Braak stages I/II, transentorhinal, Braak III/IV, limbic, and Braak V/VI, neocortical). Tracer binding in areas outside cortex were included in the partial volume correction using the Rousset method. Statistical analysis was conducted using Spearman rank correlations to assess associations between tau SUVR in the three Braak composite ROIs and age, global PiB and memory performance, and to determine the influence of PVC on these associations. **Results:** A moderate association was found between global cortical amyloid and tau SUVR in regions corresponding to Braak stages I/II, III/IV and V/VI. Weaker associations were found between age, memory performance and tau SUVR in Braak stages I/II and III/IV, and a very weak correlation was found in Braak V/VI. The strength of the associations between tau SUVR and age, PiB index and visual recall increased when using PVC (See Table), particularly for Braak stages V/VI. **Conclusion:** Our data collected in a heterogeneous sample of cognitively normal subjects, shows that tau SUVR is associated with global brain amyloid and this association tends to increase in all the Braak composite ROIs when using PVC, especially for Braak V/VI. A similar but weaker trend was found with age and memory ability.

OP-365

On- and Off-target binding of [18F]AV-1451 in Substantia Nigra post-mortem tissues of Alzheimer's Disease (AD) patients and Normal Control (NC) subjects

L. Gomez, Y. Lin, Q. Liang, M. Mintun, G. Attardo; Avid R.P., Philadelphia, PA, UNITED STATES OF AMERICA.

Purpose: It has been reported that the PET tracer [18F]AV-1451 binds to pathological tau inclusions in AD tissues but also at neuromelanin sites in the Substantia Nigra pars compacta (SNpc) (1). Strong uptake of [18F]AV-1451 in SNpc has been seen in

both AD patients and healthy subjects (2). The current study examines the binding profile of diverse chemical structures such as [18F]AV-1451, [18F]T808 and [18F]MK6240 in post-mortem brain tissue sections from AD and NCs. **Subjects and Methods:** Frozen sections from 6 AD, 5 NC cases were selected for this study. Autoradiography (ARG) and competition studies (10 μM cold) were performed using 20 μCi [18F]AV-1451, [18F]T808 or [18F]MK6240 on the brain sections (10 μm). The sections were then exposed to an imaging plate overnight and scanned with a FujiFilm Imaging System. The same sections were later stained with phospho-Tau AT8 antibody. Distribution of ARG signal of [18F]AV-1451, [18F]T808, and [18F]MK6240 are compared with that from the AT8 antibody. **Results:** The distribution of ARG signal of [18F]AV-1451 overlapped with clusters or occasionally with single cell/tangles that contained either neuromelanin or P-tau. In NCs with no positive AT8 regions, the ARG signal matched the distribution of neuromelanin-containing cells in the SNpc. In AD tissues containing P-tau immunostaining in the SNpc, characteristic spots of ARG signal overlapped clusters of neuromelanin cells and/or neuro fibrillary tangles (NFT). NFTs resulted in a much stronger ARG signal than isolated P-tau neurofilaments. Although there was no difference in average neuromelanin load between AD and NC tissues, the average ARG intensity in AD cases was non-significantly higher than in NCs . This resulted from a large P-tau load in the SNpc of the 2 AD tissues tested. Both [18F]T808 and [18F] MK6240 also showed uptake in SNpc. The intensity of the signal from [18F]AV-1451 and [18F]MK6240 were comparable. [18F]T808 showed lower intensity and minimal block of [18F]AV-1451 in SNpc of NCs. **Conclusion:** This study confirms previous reports showing that [18F]AV-1451 binds to a target in neuromelanin-containing cells in the SNpc. It also shows that in tissues where P-tau is abundant, the resulting ARG signal is likely to be the summation of Off- and On-target binding of the tracer. The binding to SNpc of tau radio ligands [18F]AV-1451 and [18F]MK6240 was clear and comparable in intensity, whereas the off-target binding of [18F] T808 was minimal. 1- Marquie et al., Ann Neurol. 2015 78(5): 787-800. 2- Hansen et al.,Brain 2016 137(7):2039-49.

OP-366

Clinical evaluation of ¹⁸F-PI-2620, a next generation tau PET agent in subjects with Alzheimer's disease, progressive supranuclear palsy, and non-demented controls

Pfeifer[3], A. Muhs[3], L. Dinkelborg[2], G. Tamagnan[1], K. Marek[1]; [1]Molecular Neuroimaging, New Haven, CT, UNITED STATES OF AMERICA, [2]Piramal Imaging, Berlin, GERMANY, [3]AC Immune SA, Lausanne, SWITZERLAND.

Introduction: Intracellular tau deposition is a key pathologic feature of Alzheimer's disease (AD) and other neurodegenerative disorders. Recently, positron emission tomography tau probes have been developed for in vivo detection of brain tau load, although quantification is challenging due to high off tar-

get binding and slow kinetics. Further, different tau radiotracers have different affinities for tau species. ¹⁸F-PI-2620 is a novel tracer with a high affinity for binding to aggregated tau. ¹⁸F-PI-2620 binds specifically to tau deposits in AD brain sections from different Braak stages, Pick's, and progressive supranuclear palsy (PSP) pathologies. This first-in-human study reported here assesses the potential of ¹⁸F-PI-2620 to visualize tau deposition in subjects with AD and PSP, in comparison with non-demented controls. **Subjects & Methods:** In an ongoing clinical imaging study, participants diagnosed with mild Alzheimer's (AD, n=4), non-AD tauopathies (e.g. PSP, n=3), and non-demented controls (NDC, n=3) undergo dynamic PET imaging for over 3 h following 370 MBq bolus injection of ¹⁸F-PI-2620. Venous blood is obtained to characterize the kinetics of parent compound and metabolites. **Results:** Initial imaging data shows robust brain uptake and fast wash-out in non-target regions with peak SUV = 4-4.5. There was no increased uptake seen in choroid plexus, basal ganglia, striatum, amygdala, meninges or other regions noted in first generation tau agents. In AD, focal asymmetric uptake was evident in temporal and parietal lobes, precuneus, and cingulate. SUVr time curves demonstrate a plateau at 90-100 min post injection with resultant SUVrs of 2.5-2.8 in abnormal regions, whilst HV demonstrated shorter time to secular equilibrium (60-70 min) and lower SUVrs (1.0-1.2) in comparable brain regions. Finally, PSP subjects demonstrated focal increased uptake in the globus pallidus (SUVr = 2.0-2.1) and substantia nigra (SUVr = 2.4-2.6). Blood data confirmed fast kinetics with 20% of parent compound present at 60 min and presence of polar metabolites. Comparison of SUVr to non-invasive pharmacokinetic modeling showed a strong correlation and linear relationship with binding potential, BPnd. **Conclusion:** Initial ¹⁸F-PI-2620 PET first-in-human data in AD, PSP and NDC demonstrate excellent brain penetrance, favorable kinetics, and high target specificity with low nonspecific binding and high signal in regions of expected tau pathology.

DLB is a highly heterogeneous disease both in terms of clinical presentation and related pathology. We aimed to investigate metabolic-patterns underlying core and suggestive features of DLB and the relative influence of disease severity. **Methods**: on April 2017 one-hundred and eighteen 18F-FDG PET scans of DLB patients were available on the functional-imaging database of E-DLB. Core symptoms (visual hallucinations, fluctuations, spontaneous Parkinsonism) and a main suggestive feature (REM-sleep-behavior disorder, RBD) information was available in seventy-nine patients (47 males, age:75.7±6.4, MMSE 22.1±5.1). The control group (CTR) was derived with a case-control design matching for age and gender from 156 FDG-PET scans from the Italian Normative-database (AIMN-FDG-PET). SPM8-two-sample t-test was used to compare CTR with the whole DLB group as well as with patients' subgroups according to the presence/absence of disease features. Age, gender and center were used as nuisance. To account for disease severity, analyses were repeated by including MMSE as a further nuisance. P<0.05 family-wise-error-corrected was considered significant. **Results**: Disease features at the time of FDG-PET were as follows: fluctuations (FLUC+) were present in 59%, Visual hallucinations (VH+) in 60%, Parkinsonism (PK+) in 76%, RBD (RBD+) in 39% of the patients. The whole DLB group was characterized by a large hypometabolic pattern involving occipital, posterior parietal, dorsolateral frontal cortex (DLFC), precuneus and caudate nuclei in both hemispheres. Looking at comparisons of single subgroups versus CTR, hypometabolism in bilateral posterior parietal cortex and precuneus was expressed in all clinical subtypes. A more extended occipital hypometabolism was evident in VH+ patients even after correction for MMSE score. DLFC hypometabolism was found in FLUC+ but not in FLUC- subgroup. This finding did not survived after correction for MMSE. The involvement of a larger portion of bilateral ventro-lateral and DLFC cortex was evident in PK+, not in PK- subgroup. RBD+ was the subgroup showing the wider cluster of hypometabolism in bilateral occipital, parietal, DLFC as compared to CTR even after correction for MMSE. **Conclusion**: We demonstrated in the largest available cohort of DLB patients ever studied with FDG-PET

that the hypometabolic pattern involving posterior-parietal cortex and precuneus is common to all DLB clinical subtypes. Occipital hypometabolism is a clinical correlate of VH irrespective of disease severity. The occurrence of RBD seems to reflect of more malignant phenotype in terms of extension of neurodegeneration, regardless of the severity of cognitive impairment. The highlighted patterns can represent the seeds for a functional-metabolic network-analysis in DLB.

OP-368

Diagnosis of Alzheimer's Disease Through Identification of Abnormality Patterns in Molecular Brain Imaging

N. Burgos[1,2], J. Samper-González[1,2], A. Bertrand[1,2,3], M. Habert[4], S. Ourselin[5,6], S. Durrleman[1,2], M. Cardoso[5,6], O. Colliot[1,2,3]; [1]Inria, Aramis project-team, Paris, FRANCE, [2]Sorbonne Universités, UPMC Univ Paris 06, Inserm, CNRS, ICM, Paris, FRANCE, [3]Pitié-Salpêtrière Hospital, Neuroradiology, Paris, FRANCE, [4]Pitié-Salpêtrière Hospital, Nuclear Medicine, Paris, FRANCE, [5]University College London, Translational Imaging Group, London, UNITED KINGDOM, [6]University College London, Dementia Research Centre, London, UNITED KINGDOM.

Background: In machine learning classification methods developed for dementia studies, neuroimaging features, e.g. glucose consumption extracted from PET images, are often used to draw the border that differentiates normality from abnormality. However, these features are affected by the anatomical and metabolic variabilities present in the population, which acts as a confounding factor making the task of finding the frontier between normality and abnormality very challenging. **Methods:** To reduce the confounding impact of these variabilities when trying to distinguish disease versus normal ageing, we developed a method able to extract for each individual the signal characteristic of abnormality from 18F-FDG PET data. Instead of comparing the patient's PET image to a population of healthy controls as usually done, this framework consists of creating a patient-specific model of healthy PET appearance, and comparing the patient's PET image to the model via a Z-score [1]. The resulting voxel-wise Z-score map can be interpreted as an abnormality map, as it statistically evaluates the localised deviation of the patient-specific uptake with respect to the healthy uptake distribution. We applied this method to 298 ADNI2 subjects (103 cognitively normal, 105 late MCI and 90 Alzheimer's disease subjects). The abnormality maps generated with the proposed method were then used as features to feed a classification algorithm based on linear support vector machines. We compared the classification results obtained using the abnormality maps to the classification results obtained using features from the native PET images, and using state-of-the-art Z-maps. **Results:** The balanced accuracy obtained with the proposed method when differentiating CN from late MCI and AD (80.5% and 91.6%, respectively) was found to be higher than the balanced accuracy obtained using PET SUVR values (78.3% and 88.9%) and the state-of-the-art Z-maps (78.7% and 89.6%) as features. The same trend was observed when differentiating amyloid positive from amyloid negative subjects (73.9% vs 71.5% and 71.4%). **Conclusions:** The high

classification accuracy obtained when using the abnormality maps as features demonstrates that the proposed pipeline is able to extract for each individual the signal characteristic of dementia from FDG PET data. Instead of trying to find the frontier between normality and abnormality at the population level, by transporting the problem to the individual level, the proposed method appears to offer a more effective way of differentiating dementia stages. OP-369

Role of 18Fluorine-Fluorodeoxyglucose positron emission tomography/computed tomography in the diagnosis of endocarditis: a bicentre study on 84 patients

P. Ferro[1], D. Albano[2], C. Popescu[3], M. Bertoli[4], I. Cersosimo[5], F. Bertagna[4], R. Sara[3], G. Giubbini[4], C. Rossetti[3]; [1]Università Milano-Bicocca, Ospedale Niguarda Ca' Granda, Milano, ITALY, [2]Università Milano-Bicocca, Spedali Civili, Brescia, ITALY, [3]Ospedale Niguarda Ca' Granda, Milano, ITALY, [4]Spedali Civili, Brescia, ITALY, [5]Demographics Pro, Beijing, CHINA.

Purpose: diagnosis of infective endocarditis (IE) is challenging and involves many different tools. The latest European Society of Cardiology guidelines introduced Nuclear Medicine imaging as a diagnostic test in patients with suspected IE. The aim of this study was to assess the role of 18F-FDG-PET/CT in the diagnosis of IE, considering qualitative and semiquantitative analysis of the images, in both native (NV) and prosthetic (PV) valves. **Methods:** 84 patients (54 male, 30 female, age range 20-94, mean 62) with suspected IE who underwent 18F-FDG-PET/CT between 2010 and 2017 were retrospectively analyzed. Clinical presentation, valve type, C-reactive-protein (CRP) and white blood cells (WBC) levels, blood-cultures, ongoing antibiotic therapy, trans-thoracic (TTE) and trans-oesophageal (TEE) echocardiography results were collected for each patients. 18F-FDG-PET/CT results were correlated with the diagnosis of endocarditis by an expert team after follow up (mean 14 months) or the Duke pathological Criteria when tissue was available. Qualitative and semiquantitative (SUV max, SUV mean, valve-to-myocardium-ratio) analysis were carried out on 18F-FDG-PET/CT images with and without attenuation correction. Statistical analysis was carried out with chi-squared test and logistic regression; p-value of ≤0.05 was considered statistically significant. **Results:** on qualitative analysis 18F-FDG-PET/CT resulted positive in 26,2% (22 patients) and negative in 72,6% (61 patients). In 1 patient the examination was inconclusive. We found a statistically significant correlation between positive 18F-FDG-PET/CT on qualitative analysis and positive blood-culture or fever (even tough fever appears in 50 patients with negative 18F-FDG-PET/CT). 65% of patients with

PV resulted positive, versus 25% with NV. In 20 cases TEE was inconclusive: in 3 cases 18F-FDG-PET/CT resulted positive (true positive), in 17 negative (respectively 15 true negative and 2 false negative). In 4 cases 18F-FDG-PET/CT subverted TEE results according to modified Duke Criteria : 1 patient from rejected to definite IE, 3 from definite to rejected IE (all cases had follow up confirmation). Mean SUVmax, SUVmean, valve-to-myocardium-ratio were higher in prosthetic valve (overall mean respectively 5.94, 4.05, 2.89; PV respectively 6.38, 4.29, 3.04). No statistically significant correlation was found between any parameter of quantitative analysis and CRP/WBC level, ongoing antibiotic therapy or recurrence of endocarditis in the follow up. **Conclusion:** 18F-FDG-PET/CT is useful in the diagnosis of suspected IE, reducing the cases classified as possible by modified Duke Criteria, especially in PV. Qualitative analysis plays a central role in the diagnosis, while further investigation must be done for a better understanding of the role of quantitative analysis.

OP-370

Digestive incidentalomas in FDG-PET/CT images of patients with infectious endocarditis; relationship with the involved microorganisms

J. J. Ardila, A. Rotger, L. Reguera, M. L. Lozano, J. Ardila, J. Orcajo, C. Duran, A. Mari, R. Pascual, J. C. Alonso; Hospital General Universitario Gregorio Marañon, Madrid, SPAIN.

Purpose: To determine the frequency of digestive incidentalomas and its relationship with neoplasias and other colorectal diseases in patients who underwent FDG PET/CT for infectious endocarditis caused by a variety of microorganisms. **Methods:** This is a retrospective study of patients with FDG-PET/CT imaging perfomed under the indication of infectious endocarditis between January 2013 to January 2017 in whom colo-rectal FDG uptake was reported. We describe the nature of the colorectal disease (confirmed with endoscopy/histopathology), the image findings and the microorganism involved. **Results:** 150 endocarditis PET CT reports were revised, obtaining gastro-intestinal findings in 18 patients. Mean age was 75 years, 13 were men and 5 women. The involved microorganisms were: S.bovis (2/18), E.faecalis (5/18), S.viridans (5/18), E.coli (2/18) and others (4/18). In the PET image the uptake was diffuse in 6 of the cases and focal in the 11 remaining. Single foci were found in 9 reports and multiple in 9. Mean SUVmax was 6,2. The morphology of the lesions was: polypoid structures in 7 patients, wall thickening in 6 and uptake without radiological translation in the remaining 5. Histologically, benign lesions were found in 55,6%, premalignant in 27,7% and malignant lesions in 16,7%. Excluding S.bovis, the frequency of onset was 37,5% of premalignant lesions and 12,5% of malignant lesions. **Conclusions:** Although the relationship between S.bovis endocarditis and colorectal lesions is well known, there is also a high prevalence of premalignant pathology and colorectal carcinoma in endocarditis caused by other microorganisms, especially E.faecalis and S.viridans. Its early detection is relevant for therapeutic management and prognosis. The need to perform a PET in this type of patients seems mandatory (prevalence of 12,5%).

OP-371

Role of 18FDG PET/MR in the diagnosis and follow-up of retroperitoneal fibrosis

P. Zucchetta, F. Crimi`, C. Lacognata, R. Marcolongo, D. Cecchin, V. Bodanza, J. Doraku, D. Miotto, F. Bui; University Hospital - Padova, Padova, ITALY.

Retroperitoneal fibrosis (RPF) is an insidious disease. Vague symptoms and lack of specific biochemical markers lead often to delayed diagnosis and difficulties in treatment evaluation. Diagnosis is usually based on CT and/or MRI, but FDG PET has been proven useful particularly in assessing disease activity during treatment. We investigated the role of integrated FDG PET/MR in the diagnosis and management of RPF. We evaluated 38 patients (F 11, M 27, mean age 64 years, min 45, max 84) by integrated ^{18}F-FDG PET/MR (Biograph mMR, Siemens). The scan was repeated during the follow-up in 14 patients (total 52 examinations). Imaging was performed following the EANM guidelines for FDG imaging and included the standard Dixon sequence for attenuation correction, transverse T1-weighted, T2-weighted (HASTE) images and Diffusion Weighted Images (DWI) with calculation of apparent diffusion coefficient (ADC) maps. Images were reviewed for disease activity ad extension. Pathological FDG uptake was scored as 0- absent, 1- present but less than liver uptake, 2- present and greater than liver uptake. Suspected RPF was the clinical indication for 14 scans, the remaining (38) were performed for treatment evaluation. Mean duration of disease was 41 months (min 1 month, max 18 years). Pathological periaortic FDG uptake was detected in 24 scans (7/14 diagnostic scans, 16/38 follow-up scans) and was concordant with MR signs of active inflammation (T2 hyperintensity and diffusion restriction signs on DWI) in 22/24 scans. FDG PET and MRI were both negative in 21 scans. In 9 cases abnormal MR findings did not correspond to hypermetabolic activity.PET/MR findings prompted the start/intensification of pharmacological treatment in 8/14 patients who repeated the scan during the follow-up, leading to a reduction/disappearance of inflammation in the second exam. Basal PET/MR documented a good control of the disease in 6/14 patients, allowing a safe tapering of the treatment. The stability of the situation was confirmed in the follow-up scans, corroborating the predictive value of ^{18}F-FDG PET/MR.[18]F-FDG PET/MR appears a promising opportunity for the diagnosis and follow-up in RPF patients. The combination of metabolic and morpho-functional parameters seems to be particularly effective in evaluating treatment response, allowing a better tailoring of corticosteroid therapy.

OP-372

Comparison of F18 FDG and Ga68 citrate PET/CT in the evaluation of patient with tuberculosis

A. O. Ankrah[1,2], I. O. Lawal[1], T. M. G. Boshomane[1], M. Vorster[1], H. C. Klein[2], A. W. M. J. Glaudemans[2], M. M. Sathekge[1]; [1]University of Pretoria, Pretoria, SOUTH AFRICA, [2]University Medical Center Groningen, Groningen, NETHERLANDS.

PET/CT with F18 FDG is increasingly playing a promising role in the evaluation of patients with tuberculosis. Ga68 citrate PET/CT is a PET tracer that images infection and inflammation and preliminary studies have suggested it may be useful in the evaluation of tuberculosis. The availability of generator produced Ga68 citrate within a department makes it an attractive alternative to F18 FDG. There is currently no literature available comparing the usefulness of these two tracers in the evaluation of tuberculosis. **Aim:** To compare the usefulness of F18 FDG and Ga68 citrate PET/CT in patients with tuberculosis. **Methods:** Patients with confirmed tuberculosis were prospectively included in the study. Patients underwent an F18 FDG PET/CT scan and a Ga68 citrate scan within one week of each other. The PET/CT scans were acquired on a Siemens biograph 40 PET/CT. The patients were scanned after l hour of injection of the tracer and scan were interpreted by 2 nuclear physicians. **Findings:** Twenty-six PET/CT scans were acquired in eleven patients at different stages of tuberculosis therapy. Six (54.5%) of the patients were male and the mean age of patients was 34.4 ± 7.8 years. 83 lesions with tracer uptake by either F18 FDG or Ga68 citrate were identified in the twenty-six PET/CT scans. F18 FDG PET/CT detected eighty-two (98.8%) with Ga68 citrate detecting seventy 84.3% of these lesions. The SUV max was significantly higher for the F18 FDG PET 7.67 $\pm$ 3.54 compared to Ga68 citrate PET which was 3.14 $\pm$ 2.25 ($p < 0.0001$). On visual inspection, the F18 FDG scans yielded much better target to background ratio compared to the Ga68 citrate which was poor in areas with a high background such as around the blood vessel in the mediastinum. One lesion demonstrated tracer uptake on Ga68 citrate with no corresponding uptake on F18 FDG PET/CT suggesting there may be a complimentary role for both F18 FDG and Ga68 citrate in the evaluation of TB. Although not completely assessed in this study, in one patient who had completed therapy neither F18 FDG nor Ga 68 citrate demonstrated tracer uptake suggesting a role for Ga68 PET/CT in monitoring response to therapy. **Conclusion:** F 18 FDG PET/CT is superior to Ga 68 citrate in the evaluation of patients with pulmonary TB. Ga 68 citrate may provide complimentary information to F18 FDG study. Further evaluation of the role of Ga68 citrate in response to therapy is needed.

OP-373

The diagnostic value of ^{18}F-FDG-PET /CT, MRI and ^{18}F-FDG-PET/MRI in suspected vertebral osteomyelitis - a prospective study

l. Kouijzer[1,2], H. Scheper[3], J. de Rooy[1], J. Bloem[3], M. Janssen[1], L. van den Hoven[2], A. Hosman[1], L. Visser[3], W. Oyen[1,4], C. Bleeker-Rovers[1], L. de Geus-Oei[3,2]; [1]Radboudumc, Nijmegen, NETHERLANDS, [2]University of Twente, Enschede, NETHERLANDS, [3]LUMC, Leiden, NETHERLANDS, [4]The Institute of Cancer Research and Royal Marsden NHS Foundation Trust, London, UNITED KINGDOM.

Introduction: The purpose of this study was to compare the diagnostic value of ^{18}F-fluorodeoxyglucose positron emission tomography with combined computed tomography (^{18}F-FDG-

PET/CT), magnetic resonance imaging (MRI), and fused ¹⁸F-FDG-PET/MRI in diagnosing vertebral osteomyelitis. **Subjects and Methods:** From November 2015 until December 2016, 32 patients with suspected vertebral osteomyelitis were prospectively included. All patients underwent both ¹⁸F-FDG-PET/CT and MRI within 48 hours. ¹⁸F-FDG-PET and MRI images were fused by soft ware fusion. All images were independently reevaluated by 2 radiologists and 2 nuclear medicine physicians. **Results:** For ¹⁸F-FDG-PET/CT, sensitivity, specificity, PPV, and NPV in diagnosing vertebral osteomyelitis were 100%, 90.9%, 95.5%, and 100%, respectively. For MRI, sensitivity, specificity, PPV, and NPV were 95.2%, 90.9%, 95.2%, and 90.9%, respectively. For ¹⁸F-FDG-PET/MRI, sensitivity, specificity, PPV, and NPV for diagnosing vertebral osteomyelitis were 100%, 90.9%, 94.4%, and 100%. MRI detected more epidural/spinal abscesses compared to ¹⁸F-FDG-PET/CT. ¹⁸F-FDG-PET/CT is more valuable in detecting metastatic infectious foci. **Conclusion:** ¹⁸F-FDG-PET/CT and MRI are both valuable techniques in diagnosing vertebral osteomyelitis. An important advantage of ¹⁸F-FDG-PET/CT is the early detection of vertebral osteomyelitis and the visualization of metastatic infection, especially in patients with bacteremia. MRI is more sensitive in detection of smaller epidural abscesses. Combined ¹⁸F-FDG-PET/MRI in a 'one-stop-shop' can incorporate these qualities and should therefore become the imaging technique of choice in suspected vertebral osteomyelitis.

OP-374

¹⁸F-FDG PET/CT as a diagnostic tool for infection assessment in post-traumatic non-unions

L. Antunovic, N. Trenti, L. Di Mento, E. Malagoli, G. Cusato, L. Balzarini, A. Kirienko, A. Chiti, M. Berlusconi; *Humanitas Clinical and Research Hospital, Rozzano, ITALY.*

Introduction: Infection is a common complication in trauma patients, especially in cases with open fractures. Sometimes clinical and radiological presentations of the infection result unclear, leading to difficulties in patient management and therapy decisions. We aimed to evaluate the diagnostic performance of ¹⁸F-FDG PET/CT in detecting infection as cause of post-traumatic bone fracture non-union. **Subjects and methods:** We retrospectively reviewed 46 patients (13 females, 33 males, age 52±19), treated in our trauma center, who underwent pre-operative 18F-FDG PET/CT scan for suspected infection in the period between January 2011 and January 2017. Clinical history, diagnostic examinations, laboratory and microbiology results and patient outcome data were collected and analyzed. A visual analysis of PET/CT scans was performed by an experienced nuclear medicine physician. The results of PET/CT were confronted with microbiological examination of the specimens taken intraoperatively. Finally, diagnostic performance of ¹⁸F-FDG PET/CT was determined. **Results:** Twenty-six patients were negative for infection, while twenty patients had positive intraoperative microbiological results. PET was able to detect the infection in 14 cases, while 6 out of 20 infected patients had no significant evidence of disease on PET images and were considered as false negatives. In 6 cases PET

showed false positive results; 20/26 disease-free patients were correctly detected by PET. There was agreement between PET results and final diagnosis in 34 out of 46 cases (74%). Sensitivity, specificity, accuracy, positive predictive value and negative predictive value of ¹⁸F-FDG PET/CT were 70%, 77%, 74%, 70% and 77% respectively. Likelihood ratio for a positive test (LR+) was 3.04. Likelihood ratio for a negative test resulted 0.39. Pre-test probability of disease was 44%; post-test probability of diseas based on LR+ resulted 71%, while post-test probability based on LR- was 24%. **Conclusions:** Our data indicate FDG PET/CT as a valuable diagnostic tool in the evaluation of post-traumatic infection. Larger datasets are needed to further corroborate our preliminary evidence.

OP-375

Relationship between WBC scintigraphy with Tc99m HMPAO-labeled leucocytes and clinical outcome in patients with suspected prosthetic joint infections

T. Pellegrino[1], M. Petretta[2], V. Cantoni[3], V. Piscopo[3], G. De Matteis[3], S. Pellegrino[3], A. Cuocolo[3]; [1]Institute of Biostructure and Bioimaging, National Council of Research, Naples, ITALY, [2]Department of Translational Medical Sciences, University Federico II, Naples, ITALY, [3]Department of Advanced Biomedical Sciences, University Federico II, Naples, ITALY.

Purpose: WBC scintigraphy is considered the gold standard nuclear imaging for diagnosing infections. However, its role in the follow-up has not yet completely elucidated. We assessed the relationship between WBC scintigraphic findings and clinical outcome in patients with suspected hip or knee prosthesis infections. **Materials and Methods:** We studied 106 patients (40 men, age 63±13 years) who underwent WBC scintigraphy with Tc-99m HMPAO-labeled leucocytes for suspected hip or knee prosthesis infections. Whole-body and spot planar images were obtained 4 hours and 24 hours after reinfusion of 555 MBq of Tc-99m HMPAO-WBC. Two nuclear medicine physicians visually reviewed all WBC imaging studies. Scans were classified as "negative for infection" if no uptake was present in both early and late images or when the uptake was the same in both images, or when the uptake decreased over time and "positive for infection" when the uptake showed an increase between early and late images or when the size of the area with enhanced uptake showed an enlargement. In patients with positive result at first WBC scintigraphy, antibiotic therapy was started after imaging and a second study was performed. **Results:** At the time of the first WBC scintigraphy prosthesis infection was suspected based on clinical examination (local or general symptoms) and on blood tests including WBC counts, C-reactive protein and erithrocyte sedimentation rate. These parameters were also considered as criteria to define the outcome of patients. The first WBC scintigraphy was negative in 24 (23%) and positive in 82 (77%) of the patients. Among the 82 patients with a positive first WBC scan, an improvement of clinical symptoms and/or of blood chemistry was present in 13 (56%) of the 23 patients with a negative WBC scan at follow-up. Moreover, 43 (73%) of the 59 patients with a positive WBC scan at follow-up did not show improvement of clinical symptoms and/or of blood

chemistry (chi-square 4.3; p<0.05). Conversely, among the 24 patients with a negative first WBC scan, there were no significant differences between clinical symptoms and/or of blood chemistry and the results of second WBC scan (chi-square 0.17; p= 0.67). **Conclusions:** Our results demonstrate that in patients with suspected prosthesis infections the presence of clinical symptoms and/or of blood chemistry signs is associated with a positive WBC scintigraphy. In addition, this imaging technique seems to be a useful noninvasive tool for the follow-up of patients undergoing antibiotic therapy.

OP-376

Typical uptake distribution patterns that help the diagnosis of polymyalgia rheumatica on FDG-PET/CT

K. Nakatani, S. Yuge, K. Yoshino, T. Koyama; Kurashiki Central Hospital, Kurashiki, JAPAN.

Purpose: Polymyalgia rheumatica (PMR) is a rheumatic disease characterized by widespread aching and stiffness in elderly people. The diagnosis of PMR is often challenging, since the clinical features of PMR and the laboratory findings can also be observed in other various inflammatory conditions. PMR is considered to have specific patterns about the affected sites, and FDG-PET/CT has an advantage for assessing the disease activity of each site. The purpose of this study was to identify the patterns of FDG uptake that contribute to the diagnosis of PMR. **Subjects and Methods:** The study population included were 60 patients (mean age = 72 ± 10, male/female = 20/40) who underwent FDG-PET/CT scans for work-up examination of suspected PMR or some kinds of arthritis, enthesitis, or myopathy between July 2007 and March 2016. Final diagnoses were made by board-certified rheumatologists. The incidence of significant FDG uptake, higher than mediastinal blood pool, of the following sites were compared between PMR patients and the others — wrists, elbows, shoulders, sternoclavicular joints, acromioclavicular joints, spinous processes, ischial tuberosities, and greater trochanters. For the spinous processes, the incidence of Y-shaped uptake along the interspinous bursa was also evaluated. **Results:** 16 of 60 patients (mean age = 75 ± 10, male/female = 1/15) had definitive diagnosis of PMR by the rheumatologists. The incidence of significant FDG uptake in the definitive PMR group versus the incidence in the other group was 6% vs. 23% (p = 0.26) for wrists; 6% vs. 18% (p = 0.42) for elbows; 88% vs. 50% (p = 0.015) for shoulders; 88% vs. 25% (p < 0.01) for sternoclavicular joints; 25% vs. 18% (p = 0.72) for acromioclavicular joints; 81% vs. 52% (p = 0.072) for spinous processes; 69% vs. 27% (p = 0.006) for ischial tuberosities; and 81% vs. 48% (p = 0.037) for greater trochanters. As for the spinous processes, patients with definitive PMR showed significantly higher incidence of Y-shaped uptake than the other patients (38% vs. 9%; p = 0.016). **Conclusion:** FDG uptake distribution patterns and the shape of FDG accumulation can contribute the diagnosis of PMR. Significant FDG uptake at sternoclavicular joints is one of the characteristic findings in patients with PMR as well as the uptake at shoulders, ischial tuberosities, and greater trochanters. Y-shaped spinous process uptake may be one of the specific findings for PMR.

Introduction: The current therapeutic options in medullary thyroid cancer (MTC) patients are very limited. Although many drugs are currently under investigation an efficient treatment regimen for advanced MTC is not available yet. We herein present first promising results of the clinical part of the GRAN-T-MTC project realized under the ERA-NET TRANSCAN. First, we aimed to assess the safety of iv administration of the gastrin analogue CP04 (DOTA-(DGlu)$_6$-Ala-Tyr-Gly-Trp-Met-Asp-Phe-NH$_2$) in an amount suitable for Peptide Receptor Radionuclide Therapy, based on the high cholecystokinin subtype 2 (CCK-2)-receptor expression in MTC. Then, we were interested to acquire first biodistribution and dosimetry data of ¹¹¹In-CP04 in MTC patients, motivated by promising results from the preclinical part of the study [1,2]. **Materials and Methods**: 4 patients (aged: 30 - 59 years) with progressive/metastatic MTC were enrolled, 3 with progressive/metastatic MEN2A-related MTC with positive ¹⁸F-FDG PET-CT/CT/MRI and one (sporadic MTC) with short calcitonin doubling time. Basal calcitonin levels ranged between 279 and 824 pg/ml. During the first clinical phase of the trial each patient received ¹¹¹In-CP04 (200 MBq) using 2 different peptide kits: a) a "diagnostic" kit containing 10 μg CP04 (kit-A) and b) a "therapeutic" kit containing a higher peptide mass of 50 μg (kit-B) [1]. Biodistribution and dosimetry data were acquired based on serial planar and SPECT/CT images. **Results**: No side effects were observed during iv injection of ¹¹¹In-CP04 from either kit. In all patients ¹¹¹In-CP04 uptake was confirmed in MTC lesions. Blood and organ clearance curves for both kits were similar. The blood clearance proceeded with a terminal half-life of 38±16 min for kit-A and 22±15 min for kit-B. The effective dose ED was ED = 0.052±0.018 mSv/MBq for both kits. Kit-B led to the highest organ absorbed doses in bladder, kidneys and colon, for ¹⁷⁷Lu: 0.54±0.06, 0.32±0.13 and 0.28±0.08 Gy/GBq,

respectively. **Conclusions**: Findings from this ongoing, phase I clinical-trial have demonstrated the safety of CP04 iv-injection in both diagnostic and therapeutic kit formulations in MTC patients. Furthermore, ¹¹¹In-CP04 could visualize all active disease sites compared to established modalities. The therapeutic use of ¹⁷⁷Lu labeled CP04 will be most probably safe up to high cumulative activity (50 GBq). **Sources of Support** GRAN-T-MTC, TRANSCAN, JTC 2011: "Validation of biomarkers for personalised cancer medicine" FP7. **References**: 1. OP-387

Lesion dosimetry in metstatic thyroid cancer treated with 131-I: method and preliminary results

E. Richetta, C. Cutaia, M. Pasquino, L. Sacco, A. Codegone, R. Pellerito, M. Stasi; AO Ordine Mauriziano di Torino, Turin, ITALY.

Introduction: A dosimetric approach to metastatic thyroid cancer treated with ¹³¹I should take into account not only the dose to the organ at risk (red marrow) but also to metastasis, often not evaluated because of time consuming and staff involvement. A SPECT-TC dose calculation method is proposed and verified. Dosimetry on a preliminary patients group is performed and the operating protocol standardized. **Subjects & Methods:** SPECT-TC Siemens Intevo was calibrated with a phantom (spheres 11.5,5.6,1.1 ml, cylinder 130 ml) filled with liquid ¹³¹I (13 MBq/ml). Acquisition (64views, 20s/view, circular-orbit, 256x256, Iterative*Flash3D* SC-AC corrected) on successive days allowed partial volume effects, dead-time and detector radius (25÷33cm) corrections in order to calculate activity and dose, whose accuracy was verified. Dosimetry was performed on 9 patients (6M,3F) after the therapeutic administration (for 2 patients in pre-therapy phase 74 MBq as well): 4 SPECT-TC were acquired (4÷6, 24, 48,96÷144 h p.i.). Metastases VOIs delineation with CT-based and threshold method allows dose calculation with MIRD spheres model on 37 lesions (24 bone, 7 lymph node, 6 pulmonary). **Results:** Calibration factors (cylinder:25.4, smallest sphere:1.4 kcts/MBq) confirmed partial volume effects (130ml:100%, 11ml:75%, 5.5ml:58%, 1.1ml:6%) and radius dependence (~10%). Dead-time strongly influences counts in early acquisition (up to 17 %) and it was corrected (fit (r² 0.99) between equipment's dead-time index and true counts). Mean accuracy on activity -15% [-9% ÷ -24%] and dose -13 % [-9 % ÷ -18%] for volumes larger than 2.5 cc (up to 70% for smaller volumes not suitable for dose estimation) validates the dosimetric method, according to literature (MIRD24). Dose to lesions per activity unit varies widely among patients (mean ± 1dev.st 26±38, range 0.1÷189 Gy/GBq) and within the same patient (up to +583 %) also for the same type of metastasis, confirming the need of an individualized dosimetry. Volume segmentation influences the dose: CT-based method is strongly recommended and gives in mean - 4.9 % [+0.3 ÷ -17 %] lower results compared to the isocontour threshold one. In-therapy dose values show high differences (up to -126%) compared to pre-therapy results, whose efficacy must be further investigated with more patients

also in terms of optimal activity to be administered to simulate the treatment. **Conclusions:** Lesion dosimetry of metastatic thyroid cancer treated with radioiodine can be performed accurately with SPECT-TC. The dosimetric approach provides to the physician a fundamental tool to optimize the treatment as required by the national and European laws.

OP-388

Analysis deviation of the absorbed dose of thyroid for Graves' disease with hyperthyroidism treated by iodine-131 with simplified Quimby-Marinelli-Hine formula method

Y. Chen; Quanzhou 1st Hospital, Quanzhou, CHINA.

Purpose: Deviation of the absorbed dose of thyroid (TD) was evaluated in Graves' diseases with hyperthyroidism treated by iodine-131 with the simplified Quimby-Marinelli-Hine formula method (sQMHF). **Subjects & Method:** Continuous 45 Graves' disease with hyperthyroidism (12 male, 33 female, 43.9y±12.9y) were included in this study. Thyroid masses (TM) were measured by ultrasound. Then, the average energy ($\bar{E}$) being deposited in thyroid per decay of iodine-131 was calculated. Radioiodine uptake (*RAIU*) were tested at 2h, 4-6h, 24h, 48-72h, and 96-168h, then $T_{1/2eff}$ and resident time (*RT*) was computed. According to the sQMHF, a prescribed TD set at 75Gy requires 3.7MBq/g of iodine-131 corrected by $RAIU_{24h}$. Then the real TD was computed through Standard Operational Procedures for dosimetry (SOPD) prior to radioiodine therapy of benign thyroid disease that was recommended by European Association of Nuclear Medicine (EANM), and its error was recorded as Res . The data were analyzed by *t*-test. **Results:** The TM was (35.2±22.5) g, while $\bar{E}$ was (2.83±0.05) Gy•g•d^{-1}•MBq^{-1}. The $RAIU_{24h}$, $T_{1/2eff}$ and RT was 0.543±0.132, (3.46±0.90) d, (3.15±1.15) d, respectively. The actual TD was(89.4±9.6)Gy and its Res was 5.1%±2.9%, when the prescribed TD set at 75Gy with sQMHF. They were significant difference (*t*-value 9.84, *P*<0.01) for the sQMHF ignores the absorbed dose deposited in thyroid during the first 24h which is included in the SOPD. The Res of actual TD was significantly less than the difference between actual and prescribed TD (*t*-value -32.4, *P*<0.01). **Conclusion:** When the activity of iodine-131 calculated by the sQMHF, the real TD was significantly larger than prescribed dose. The error of TD could be decreased by computing the activity of iodine-131 with SOPD. Key Words: Radioiodine uptake; effective half-life; residence time; absorbed dose

OP-389

Micro-scale Modeling for the Salivary Gland: Insights into Toxicity from ^{131}I Therapy for Thyroid Cancer

R. F. Hobbs[1], A. McGuffey[1], W. Jentzen[2], D. Plyku[1], A. Bockisch[2], G. Sgouros[1]; [1]Johns Hopkins University, Baltimore, MD, UNITED STATES OF AMERICA, [2]Universitaet Duisburg-Essen, Essen, GERMANY.

Objectives: Salivary gland toxicity is a quality of life concern in radioiodine treatment of thyroid cancer. Clinically observed toxicity is inconsistent with absorbed doses (AD) to the salivary glands calculated by absorbed fraction methods, nor by personalized Monte Carlo-based voxelized 3-dimensional radiobiological dosimetry (3D-RD) calculations, which includes accounting for dose rate effects as well as contribution to AD from outside the salivary glands. Micro-scale anatomical modeling has been proven to reconcile discrepancies between whole organ AD values and clinically or pre-clinically observed toxicities. **Methods**: We apply a micro-scale model to account for localization of radioiodine (or astatine) uptake. Uptake in the salivary glands has been shown to be primarily confined to the epithelial striated ducts which contain sodium iodine symporters. Dimensions of typical striated duct cells were obtained from the literature and S-values for the striated cells for various isotopes of iodine and astatine (^{131}I, ^{124}I, ^{123}I, ^{125}I, ^{211}At) used in clinical or pre-clinical scenarios were calculated using GEANT4 Monte Carlo. Based on the fraction of occupancy of these cells within the salivary glands, a grid of striated cells placed randomly in spheres of increasing size was used to simulate decay of activity in these cells from which ratios of striated duct AD and acinar cell AD to whole organ AD were calculated for these same isotopes. **Results**: S-values for striated duct to striated duct as well as striated duct to acinar cells as a function of distance from the striated duct were calculated, as were S-values for contents (saliva) inside the tube formed by the striated ducts to the same target cells. The grid-based Monte Carlo results showed a ductal cell AD to salivary whole organ AD ratio of 3.5 - 3.3 for ^{131}I and 14.6 for ^{211}At dependent on salivary gland size (5 - 25 ml). Ratios for ^{124}I, ^{123}I, ^{125}I were also calculated and AD distributions (DVHs) of the acinar cells were established for each isotope, normalized to whole organ AD. **Conclusions**: This is a significant step in quantifying the discrepancy between clinically observed toxicity and predicted toxicity based on whole organ AD values. This approach uses micro-scale dosimetry, which has been shown to explain similar discrepancies in different cases, particularly alpha-particle dosimetry. This study shows that while the salivary glands may be considered as parallel organs for external beam radiation, the physiology for iodine uptake means that for radiodine therapy, they have a more complex structure.

OP-390

Dose-response correlation in radioiodine therapy of hyperthyroidism from nodular thyroid disease

M. Pacilio[1], G. Ventroni[2], V. Frantellizzi[3], B. Cassano[4], E. Verdolino[4], T. Montesano[3], G. De Vincentis[3], L. Mango[2]; [1]Department of Medical Physics, Azienda Ospedaliera Universitaria Policlinico Umberto I, Rome, ITALY, [2]Department of Nuclear Medicine, Azienda Ospedaliera San Camillo Forlanini, Rome, ITALY, [3]Department of Radiological, Oncological and Anatomo Pathological Sciences, "Sapienza" University of Rome, Rome, ITALY, [4]Postgraduate School of Medical Physics, "Sapienza" University of Rome, Rome, ITALY.

Introduction: Radioiodine therapy of hyperthyroidism is a well-established modality of treatment, alternative to surgery. The EANM Dosimetry Committee recommends treatment optimization by pretherapeutic dosimetry based on the assess-

ment of the individual ^{131}I kinetics in the target tissue, after the administration of a tracer activity. Despite that, many clinicians still consider patient-specific dosimetry of doubtful value in this context, claiming that empiric methodologies or administration of fixed activities show analogous effectiveness, sparing time-consuming pretherapeutic studies. The aim of this work was to highlight the added value of patient-specific dosimetry in radioiodine therapy of hyperthyroidism from nodular thyroid disease. **Methods:** 374 patients affected by autonomous thyroid nodule and multinodular goitre underwent radioiodine therapy. All treated patients presented hyperthyroidism from blood tests (TSH, and/or FT3, FT4) before the treatment. Post-therapy follow-up lasted for at least 1 year. The healing was defined as absence of hyperthyroidism (as evidenced by blood tests) at 1 year from the therapy, after the first radioiodine treatment. 187 treatments were performed with an empiric methodology, not basing on a pre-treatment dosimetric study. 187 treatments were dosimetry-based, following the EANM Dosimetry Committee recommendations (collecting just three biokinetics points), and these include also 67 treatments based on a biologically effective dose (BED) prescription. In general, the use of the BED was also tested in the result analysis for all dosimetry-based treatments. Statistical analysis was performed by Mann-Withney and Chi-squared test, univariate receiver operating characteristics (ROC) analysis, and interpolation of dose-response data by a logistic model. **Results:** For the 120 treatments based on absorbed dose prescriptions, there were significant dosimetric differences between the unhealed and the healed group (p=0.0067), also when the absorbed dose values were converted in BED (p=0.0049), and the Area-under-curve (AUC) was 0.758 and 0.770, respectively. The absorbed dose/BED-response curves had regular trends with r-value of 0.980 and 0.984, respectively. The healing probability obtained from the BED-based treatments was not statistically different from that of treatments based on absorbed dose prescriptions (p=0.423). Considering the total 187 dosimetry-based treatments, the absorbed dose/BED-response curves confirmed regular trends with r-value of 0.979 and 0.977, respectively. The absorbed dose associated to a healing probability of 50% and 95%, was 42.6 Gy and 242.3 Gy, respectively. The probability of recurrence was 9.6%, exactly half of that associated to the empiric treatment group (19.3%, p=0.0081). **Conclusion:** Patient-specific dosimetry has proven to increase therapeutic effectiveness, reducing the recurrence frequency and the need of repeated treatments.

OP-391

First-in-human administration of the CCK-2 receptor agonist ^{177}Lu-PP-F11N in patients with metastasized medullary thyroid carcinoma - preliminary results of the "Lumed" trial

C. Rottenburger[1], G. Nicolas[1], L. McDougall[1], F. Kaul[1], E. Christ[1], R. Schibli[2], S. Geistlich[2], M. Béhé[2], D. Wild[1]; [1]University of Basel Hospital, Basel, SWITZERLAND, [2]Paul Scherrer Institut, Villigen, SWITZERLAND.

Aim: There is a clinical need to improve imaging and therapy of patients with medullary thyroid cancer (MTC). One possibility is

targeting the cholecystokinine-2 (CCK-2) receptor with radiolabeled gastrin analogues because MTC express CCK-2 receptors at a high incidence and density. Unfortunately, kidney and bone marrow toxicity precluded therapeutic applications of CCK-2 receptor specific compounds until now. The aim of this study is the feasibility testing of targeting CCK-2 receptors with the novel ^{177}Lu labelled gastrin analogue PP-F11N [DOTA-(DGlu)6-Ala-Tyr-Gly-Trp-Nleu-Asp-PheNH2] in six patients with metastasized MTC (ClinicalTrials.gov: NCT02088645). **Materials and Methods:** So far 2/6 patients received two injections of 1 GBq ^{177}Lu-PP-F11N, one injection without and the other one with Physiogel (Gelofusin) infusion for the evaluation of a possible strategy for nephroprotection. Planar scintigraphy and SPECT/CT scans were performed at several time points for up to 72 h post injection in order to calculate tumor- and organ doses using 3D voxel-based dosimetry (STRATOS software). Blood samples were taken for bone marrow dosimetry. ECG, blood count and blood chemistry were measured up to 12 weeks after the second administration of ^{177}Lu-PP-F11N in order to evaluate adverse events. **Results:** Apart from flushing, nausea and vomiting (grade 1 according to CTCAE version 4.0) at the time of injection, there were no adverse reactions observed. In both patients, multiple tumor localizations were visible on planar scintigraphic and SPECT/CT images. The median of the mean radiation dose to evaluated metastases was 9.97 Gy/GBq (range 3.29 - 19.5). The organ with the highest radiation dose was the stomach (median of the mean 2.08 Gy/GBq; range 1.75 - 2.85), followed by the kidneys. Intraindividual kidney radiation doses were lower when Physiogel was co-administered (patient 1: 1.04 versus 1.56; patient 2: 0.72 versus 1.08 Gy/GBq). The highest bone marrow dose was 0.0101 Gy/GBq. These data suggests that the administration of up to 3 cycles of 7.4 GBq ^{177}Lu-PP-F11N might be possible in individual patients before a dose limiting toxicity is reached, resulting in possible cumulative tumor doses of more than 400 Gy. **Conclusion:** The administration of ^{177}Lu-PP-F11N was safe in the first two examined patients without serious adverse reactions. Imaging and dosimetry of MTC metastases indicates tumor doses feasible for radionuclide therapy. Dosimetry studies identified the stomach and kidneys as possible dose limiting organs. However, the co-administration of Physiogel seems to be a suitable strategy for nephroprotection. These promising preliminary results warrants further clinical evaluation of ^{177}Lu-PP-F11N.

OP-392

Red marrow dosimetry in metastatic thyroid cancer treated with 131-I: a simplified method

*E. Richetta, **G. Lo Moro**, C. Cutaia, M. Pasquino, L. Sacco, G. Brusasco, R. Pellerito, M. Stasi; AO Ordine Mauriziano di Torino, Turin, ITALY.*

Introduction: A dosimetric approach to metastatic thyroid cancer treated with 131-I should calculate the dose to red marrow or blood as main organ at risk. In this study a simplified method for calculating dose is proposed. **Subjects & Methods:** According to MIRD formalism, after the 131-I administration, doses to red marrow or blood are obtained from whole body and blood residence times, derived from uptake measurements and blood

samples. Hanscheid (2009) has proposed a simplified method on a 29 patients group: under the assumption that 14 % (dt%) of the whole-body residence time can be attributed to blood, blood residence time (t_{bl}) can be calculate from whole-body time (t_{wb}) as $t_{bl}=t_{wb}\times dt\%/(100\times BLV)$, where BLV is the individual blood volume derived from weight and height. On a group of 82 patients, 102 blood residence times were calculated with standard (stdm) and simplified (sm) method, after the verification of the dt% value, both in-therapy and pre-therapy phase. Doses to red marrow and blood were compared to evaluate the overall agreement. **Results:** Blood residence time percentage (dt%) was in mean 12% (range 7%÷19%). This value was used to calculate the blood residence time for the simplified method. Both in-therapy t_{bl} (h•ml) (sm 6.39E-04 ±1.89E-04 vs stdm 6.18E-04±1.82E-04) and pre-therapy t_{bl} (h•ml) (6.35E-04±2.05E-04 vs stdm 6.15E-04±1.95E-04) were not significant statistical different (p-value > 0.05 t-test paired samples). In-therapy doses (cGy/GBq) to red marrow (sm 7.18±2.01 vs stdm 7.04±1.88) showed a mean percentage difference 2.13% (range -24%÷+34%); the Bland-Altman analysis confirmed the accuracy of the simplified method also compared to the 2 Gy dose limit. Similar results were obtained for blood doses (sm 9.35±2.61 vs stdm 9.12±2.44), with mean percentage difference equal to -1.06% (range -30%÷+41%). No statistical differences were found between in-therapy and pre-therapy doses as well. **Conclusion:** A simplified method to calculate dose to red marrow and and blood in methastatic thyroid patients treated with radioiodine was applied on a larger dataset of patients. Results confirmed the accuracy of the formalism that represents a simplified dosimetric approach, feasible for all institutions, mandatory in high dose treatments and required by national and european laws, to optimize the therapy.

OP-393

Differences in radioiodine biokinetics between papillary thyroid carcinoma low-risk patients treated with 1.11 GBq of ^{131}I-NaI and high-risk patients treated with 3.7 GBq of ^{131}I-NaI

P. Mínguez Gabiña[1], M. Domínguez Ayala[2], A. Expósito Rodríguez[2], J. Genollá Subirats[1], E. Rodeño Ortiz de Zarate[1]; [1]Gurutzeta/Cruces University Hospital, Barakaldo, SPAIN, [2]Basurto University Hospital, Barakaldo, SPAIN.

Purpose/Introduction: Administration of ^{131}I-NaI for postoperative ablation of thyroid remnants for the treatment of differentiated thyroid cancer has been performed since the 1940s. The optimal activity to administer is still a matter for discussion, as some studies have reached different conclusions after administering activities between 1.11 GBq and 3.7 GBq. In this study, we have focused on possible differences in radioiodine biokinetics between patients treated for papillary thyroid carcinoma with 1.11 GBq (low-risk patients — pT1-T2 tumours without lymph node or distant metastases.) and patients treated with 3.7 GBq (high-risk patients — pT3-T4 tumours or metastases). **Subjects & Methods:** 50 patients with papillary thyroid carcinoma were included in the study. Of them, 18 were low-risk patients and

32 were high-risk patients. Prior to radioiodine therapy, all patients underwent total thyroidectomy. Some patients had more than one remnant and in total 81 remnants were included. Low-risk patients were treated with 1.11 GBq of ^{131}I-NaI and high-risk patients with 3.7 GBq. The activity at 2 d and 7 d post-administration taken up by thyroid remnants and the mass of thyroid remnants were determined from SPECT/CT images using thresholding techniques and recovery coefficients. From these parameters, the remnant absorbed dose was calculated integrating the time-activity curve with a rectangular integration until the first time-point and thereafter assuming a monoexponentially decaying activity. The S-value was derived from interpolation of values of unit-density spheres. **Results:** For all results, mean values are given and results of low-risk patients treated with 1.11 GBq appear first. An independent samples *t*-test was performed for the analysed parameters and the *p*-value is shown. Remnant masses were 3.2 g and 3.6 g (*p*=0.43). Remnants activities at 2d post-administration were 5.2 MBq and 6.1 MBq (*p*=0.60). Remnants activities at 7d post-administration were 2.4 MBq and 0.7 MBq (*p*=0.02). Effective half-lives of the radioiodine were 99 h and 48 h (*p*=7.3x10[-9]). Remnants absorbed doses were 38 Gy and 22 Gy (*p*=0.15). **Conclusion:** Remarkable differences were found in the biokinetics of the radioiodine in the thyroid remnants between low-risk (1.11 GBq of ^{131}I-NaI administered) and high-risk patients (3.7 GBq of ^{131}I-NaI administered) treated for papillary thyroid carcinoma. These differences may be due to the differences in the stage of the disease, or to a different response of thyroid remnants to the amount of activity delivered. This situation calls for further investigation in order to give an explanation for our results.

Radiolabelling with carbon-11 of sulfasalazine for PET imaging of cystine transporter X_c^- involved in the radioresistance of glioblastoma

*M. Morloz, M. Ibazizene, C. Perrio, L. Barre, **F. Gourand**; Cyceron, UNICAEN, CEA, CNRS, ISTCT/LDM-TEP group, Caen, FRANCE.*

Introduction: Glioblastomas (GBMs) are aggressive brain tumors resistant to chemotherapy and radiotherapy. Tumor cells survival is related to an increased concentration of the antioxidant glutathione (GSH) which inhibits the action of Reactive Oxygen Species (ROS) produced by radiotherapy.[1] Accumulation of GSH is due to a surexpression of cystine transporter X_c^-, cystine being the precursor of GSH. The anti-inflammatory drug sulfasalazine has been reported to be an inhibitor of the system X_c^- and we sought to label this compound with carbon-11.[2] PET imaging studies using this new tracer could contribute to elucidate the role of system X_c^- in the efficacy of radiotherapies for GBMs patients. **Materials and Methods:** We examined two methods to label sulfasalazine at the

carboxylic acid position. The first strategy was the direct carboxylation with [^{11}C]CO$_2$ of sulfasalazine organomagnesium precursor. The other alternative to synthesize [^{11}C]sulfasalazine was the coupling reaction of [^{11}C]salicylic acid with a diazonium salt in basic aqueous conditions. **Results**: All attempts to obtain [^{11}C]sulfasalazine according to the direct carboxylation strategy failed. To circumvent this approach, the coupling reaction of [^{11}C]salicylic acid with the diazonium salt has been performed in presence of NaOH under different conditions (temperature, time, reagents and precursors concentrations). After optimization, [^{11}C]sulfasalazine has been obtained with a conversion rate of 40% (based on HPLC profiles). **Conclusion:** [^{11}C]Sulfasalazine was successfully obtained by a two-step radiosynthesis from [^{11}C]CO$_2$ including formation of [^{11}C]salicylic acid then coupling with a diazonium salt. Preclinical studies are in progress to better understand the role of system X$_c^-$ in GBMs. 1-Sleire *et al, Oncogene,* 2015, 34, 5951 2-Lewerenz *et al, Antioxid Redox Signal,* 2013, 18, 522

OP-395

A Successive Triple PET Tracer Approach to Characterize ER and HER2 Status In Vivo in a Breast Cancer Mouse Xenograft Model

M. Paquette, S. Beaudoin, S. Phoenix, L. Fafard-Couture, É. E. Turcotte, B. Guérin, R. Lecomte, J. V. Leyton; Université de Sherbrooke, Sherbrooke, QC, CANADA.

Introduction: Estrogen Receptor (ER) and HER2 status are two of the most important prognosis factors in breast cancer, the presence of either strongly dictating the optimal course of therapy to undertake. ER+ diseases are likely to respond well to adjuvant hormone therapies, whereas HER2-overexpressing tumors can be efficiently treated with the anti-HER2 antibody trastuzumab. This study aims at designing a preclinical PET imaging protocol for sequentially monitoring glucose consumption, ER and HER2 within a 7-day schedule using [^{18}F]-FDG, the ER radiotracer 4-fluoro-11β-methoxy-16α-[^{18}F]-fluoroestradiol ([^{18}F]-4FMFES) and the HER2-targeting ^{89}Zr-labeled trastuzumab in succession. **Subjects and Methods**: Both conjugation of *p*-isothiocyanatobenzyl-desferrioxamine (DFO) to trastuzumab and labeling with [^{89}Zr]-oxalate were carried out using known standard procedures. Purification and buffer exchange with PBS of ^{89}Zr-trastuzumab were performed by serial centrifugal filtration. ^{89}Zr-trastuzumab was radiochemically characterized using instant thin layer chromatography eluted with 0.1M DTPA. ^{18}F-4FMFES and ^{18}F-FDG were prepared as previously described. The MCF7 (ER+, HER2-) and JimT1 (ER-, HER2+) human breast cancer cell lines were engrafted subcutaneously on the shoulder of female athymic nude mice. On day 1, PET imaging was performed 45 minutes after injection of 4.5±1.9 MBq [^{18}F]-FDG. On day 2, 2.6±0.3 MBq of [^{18}F]-4FMFES was administered followed by PET imaging 1 h post-injection. The same day, mice were again injected with ~50 µg (3.9±0.4 MBq) ^{89}Zr-trastuzumab. A 20-minute PET acquisition was obtained at 2 and 6 days post-injection, followed by a low-dose CT. A semi-quantitative analysis of the tracer uptake in tumors was carried out to obtain %ID/g data. **Results**: Specific activity for [^{89}Zr]-trastuzumab reached 83 MBq/mg (25.1 TBq/mmol), with radiochemical purity ≥95%. [^{18}F]-FDG uptake averaged 2.5±0.2 %ID/g for MCF7 and 2.1±0.8 %ID/g for JimT1 tumors, respectively. Differential 4FMFES uptake was observed, reaching 2.3±1.2 %ID/g for MCF7 tumors, but only 0.8±0.3 %ID/g for ER- JimT1 tumors. [^{89}Zr]-trastuzumab uptake for the HER2+ JimT1 tumors reached 16.3±2.5 %ID/g and 19.9±3.2 %ID/g at 2 and 6 days post-injection respectively, whereas MCF7 uptake was consistently ~3-fold lower. **Conclusion**: This pilot study showed the feasibility of a triple-tracer preclinical PET imaging protocol of breast cancer within a 1-week schedule. Such a protocol enables whole-body *in vivo* discrimination between tumors having different ER and HER2 expression patterns. It could also predict therapy efficacy and help monitor ER/HER2 status switch longitudinally.

OP-396

In vivo tracking of T cells by [18F]BF4 PET/CT in a mouse model of human breast cancer

E. Kurtys[1], L. Lim[1], F. Man[1], A. Volpe[1], J. Maher[2], G. O. Fruhwirth[1,3]; [1]Department of Imaging Chemistry and Biology, Division of Imaging Sciences and Biomedical Engineering, St. Thomas' Hospital Campus, King's College London, London, UNITED KINGDOM, [2]Division of Cancer Studies, King's College London, SE1 9RT, UK, London, UNITED KINGDOM, [3]Comprehensive Cancer Imaging Centre King's College London & UCL, London, UNITED KINGDOM.

Aim: Genetically modified T cells are emerging as a promising tool for personalised anti-cancer immunotherapy. Big challenges remain for them in solid tumour therapy such as in vivo relocalization reducing on-site efficacy and on-target off-site toxicities against healthy tissues. In vivo imaging of these cellular therapeutics can not only inform their development but also inform individual therapy monitoring/dosing. The goal of the present study was to quantify anti-ErbB family Chimeric Antigen Receptor (CAR) T cells in a mouse model of human breast cancer. These therapeutic cells were rendered traceable in vivo by PET and SPECT imaging via a multi-modal multi-scale reporter gene approach. **Material and Methods:** The human sodium iodide symporter (NIS) was fused to a red fluorescent protein (RFP)[1] and co-expressed in human T-cells with the T1E28z CAR targeting the ErbB receptor family[2]. CAR::NIS-RFP Tcells were lentivirally transduced and selectively expanded via the chimeric IL-4:IL-2/15 cytokine receptor approach[3] CAR::NIS T cells were characterised in vitro for their ability to kill MDA-MB-436 cells as well as their ability to take up the NIS PET tracers [^{18}F] tetrafluoroborate ([^{18}F]BF$_4$) and [^{99m}Tc]pertechnetate (^{99m}TcO$_4^-$). MDA-MB-436 breast tumours were established in female immunodeficient NOD scid gamma (NSG) mice either orthotopically or subcutaneously. CAR::NIS T cells were injected either systemically or intratumorally into establbished tumours and followed by PET/CT imaging up to two weeks post injection. After the last scan mice were sacrificed and tissues were collected for ex-vivo biodistribution by gamm-counting and histology. **Results:** Live CAR::NIS T cells were successfully detected at various concentration levels in naïve as well as tumour-bearing animals by [^{18}F]BF$_4$

PET/CT imaging. Intratumourally administered CAR::NIS T cells could be followed in vivo over a period of 15 days. At this time point significant amounts (>66%) had left the tumour and/or died. Systemically administered (i/v) CAR::NIS T cells could be detected in primary tumours in both models within 24h of administration and were successfully tracked longitudinally at the primary tumours. Importantly, systemic administration resulted also in on-target off-site localization. Ex vivo biodistribution and histology confirmed our in vivo imaging results. **Conclusion:** NIS reporter gene imaging by [18F]BF$_4^-$ -PET is a sensitive tool for monitoring anti-cancer T cell therapy. In vivo imaging allowed quantification of T cells distribution and retention in primary tumours. Imaging informed on T cell tumour presence, which is a prerequisite for any therapeutic effect.1. OP-397

Differentiation of CNS lymphoma and glioblastoma with [18F]fludarabine-PET: comparison with [18F]FDG in human xenograft models

N. Hovhannisyan[1], S. Guillouet[1], M. Dhilly[1], M. Ibazizene[1], F. Fillesoye[1], S. Valable[2], B. Plancoulaine[3], L. Barré[1]; [1]Normandie Univ, UNICAEN, CEA, CNRS, CHU Caen, ISTCT/LDM-TEP group, Caen, FRANCE, [2]Normandie Univ, UNICAEN, CEA, CNRS, CHU Caen, ISTCT/CERVOxy group, Caen, FRANCE, [3]Normandie Univ, UNICAEN, INSERM, ANTICIPE, Caen, FRANCE.

Introduction: [18F]Fludarabine is a PET radiotracer [1], the specificity of which has been studied in several lymphoma models (follicular RL7, DOHH2; MM RPMI8226) and under various conditions such as cancerous tissue following therapy and inflammation [2-4]. The first-in-human study in two types of lymphoid malignancies (DLBCL, CLL) has consolidated the great potential of this innovative tool for lymphoma imaging in oncology [5,6]. The purpose of this study was to investigate whether [18F]fludarabine-PET can help differentiate between central nervous system (CNS) lymphoma and glioblastoma (GBM), considering also multimodal analyses with [18F]FDG, MRI and histology. **Methods:** Nude rats were implanted with human MC116 lymphoma- (n=10) or U87 glioma-cells (n=5). Tumor growth was monitored by MRI (7-Tesla, Bruker), with T2-weighted sequence (RARE) for anatomical features and T1-weighted (EPI) with gadolinium (Gd) enhancement for BBB permeability assessment. For PET investigation (Inveon, Siemens), ~11 MBq [18F]fludarabine or [18F]FDG were injected via tail vein and PET dynamic images were acquired up to 90 min after radiotracer injection. Paired scans of the same rat with the two [18F]-labelled radiotracers were investigated. Initial volumes of interest (tumor and healthy contralateral or cerebellum tissue) were manually delineated on T2w image and set on co-registered PET image (Pmod 3.7) and tumour-to-background ratios (TBR) were calculated to semi-quantitatively assess the tracer accumulation in the tumour. **Results:** In lymphoma model, PET time-activity curves revealed a differential response of [18F]fludarabine between tumoral and healthy tissues with average TBR varying from 2.45 to 3.16 between 5 to 90 min post-injection. In contrast, [18F]FDG demonstrated similar uptake profiles for tumoral and normal regions with TBR varying from 0.84 to 1.06 between these two time points. In GBM model, the average TBRs were from 1.67 to 1.07 for [18F]fludarabine and from 1.08 to 1.65 for [18F]FDG. Therefore, inter-model comparisons showed significantly divergent responses (p<0.001) of [18F]fludarabine between lymphoma and GBM, while [18F]FDG demonstrated considerable overlap (p=0.04) between the groups. Tumour characterisation with histology (based mainly on Hoechst, CD68 and CD79), as well as with MRI were in overall better agreement with [18F]fludarabine-PET than [18F]FDG with regard to tumour selectivity. **Conclusion:** The potential of [18F]fludarabine-PET to distinguish CNS lymphoma from GBM is quite evident and will be further investigated. OP-398

Convenient synthesis and biological evaluation of 18F-labeled MIBG analog with an improved detectability

A. Yamaguchi, H. Hanaoka, T. Higuchi, Y. Tsushima; Gunma University Graduate School of Medicine, Maebashi, JAPAN.

Aim: Radioiodine-labeled MIBG play roles in diagnosis and therapy for the neuroendocrine tumors including neuroblastoma and pheochromocytoma. To improve detectability of [123I]MIBG, efforts have been made for the development of 18F-labeled MIBG derivatives. Although 4-[18F]fluoro-3-iodobenzylguanidine (FIBG) holds a promising basic properties, its tumor imaging capability remains obscure probably because of the complexity in the radiolabeling procedure [1, 2]. In contrast, recent astonishing progress in the late-stage [18F]fluorination enabled production of 18F-labeled compounds which previously believed difficult to develop. Our aim was to establish an improved radiosynthetic method for [18F]FIBG by applying late-stage [18F]fluorination. Its usefulness as a PET imaging agent for the detection of neuroendocrine tumor was also evaluated. **Materials and Methods:** [18F]FIBG was prepared from a (mesityl)(aryl)iodonium salt precursor in the presence of a copper-catalyst, according to the procedure by Sanford and Scott [3] with a brief modification. Biodistribution studies were performed on PC-12 rat pheochromocytoma cell xenograft mice using [18F]FIBG, [125I]FIBG or [125I]MIBG. PET imaging was performed on PC-12 xenograft mice after 1 h injection of [18F]FIBG. **Results:** tetra-*N*-Boc-protected [18F]FIBG was obtained from the iodonium salt precursor in the presence of a copper-catalyst (5 equivalent) with the radiochemical yield of 18.3 ± 8.5 % (decay corrected, n = 9). Subsequent deprotection using 6 N HCl followed by HPLC purification readily produced desired [18F]FIBG. In biodistribution study in PC-12 mice, all MIBG analogs exhibited similar distribution profiles and showed highest uptake in the tumor. The tumor uptake of [18F]FIBG was slightly higher than that of [125I]MIBG though not statistically significant (41.5 ± 14.5 %ID/g and 35.4 ± 13.3 %ID/g,

respectively). In PET imaging in xenograft mice, [18F]FIBG clearly depicted the tumor, even for a small one (4 mm), as early as 1 h after injection with excellent tumor-to-background ratios, as oppose to [123I]MIBG which requires 24 h to produce high-contrast image. **Conclusion:** We successfully produced [18F]FIBG in 2 steps by using late-stage [18F]fluorination. [18F]FIBG accumulated in the tumor as high as [125I]MIBG in the PC-12 xenograft mice. Moreover, in PET imaging, [18F]FIBG clearly depicted the tumor with excellent tumor-to-background ratios. These results indicates [18F]FIBG constitute a promising PET imaging agent for the detection of neuroendocrine tumors. **References:** [1] J. Med. Chem. 1994, 37, 3655-3662 [2] J Nucl Med 1995; 36: 644-650 [3] Org. Lett. 2014; 16: 3224–3227

OP-399

Targeting glucose metabolism and EGFR signaling in oncogene-driven non-small cell lung cancer

V. De Rosa[1], *F. Iommelli*[1], *M. Monti*[2], *C. Terlizzi*[2], *S. Del Vecchio*[2,1]; [1]*Institute of Biostructures and Bioimaging, National Research Council, Naples, ITALY*, [2]*Department of Advanced Biomedical Sciences, University of Naples "Federico II", Naples, ITALY.*

Aim: In a previous study we showed that inhibition of EGFR signaling causes a metabolic switch from aerobic glycolysis to oxidative phosphorylation by reducing hexokinase II (HKII) and phosphorylated form of pyruvate kinase M2 (p-PKM2 Tyr105) and upregulation of mitochondrial complexes (OXPHOS) in NSCLC cells and animal models. Here we tested whether the simultaneous targeting of glucose metabolism and EGFR signaling may enhance tumor response to tyrosine kinases inhibitors (TKIs) in NSCLC. **Materials and Methods:** To this end, resistant H1975 and H1993 NSCLC cells were transfected with 100 nM of scrambled or PKM2, LDH-A and PDK1 targeted siRNAs using Dharmafect reagent and after 24 h they were treated with 1 μM TKIs (WZ4002, PHA-665,752) or vehicle for additional 48 h. Toxicity of combined treatment was tested by MTS assays. Furthermore, we tested the levels of HKII, PKM2, LDH-A, PDH and PDK1 along with the phosphorylation status of PKM2 and PDH in response to treatment with targeted siRNAs, selective TKIs or combination of both agents. In parallel experiments, glucose consumption and ATP production were determined in untreated and TKIs treated cells, in the presence or absence of specific siRNA. **Results:** A reduction of cell viability of both cell lines was observed in response to TKIs and was enhanced by the concomitant silencing of PKM2 or PDK1. Inhibition of EGFR signaling caused downregulation of HKII, p-PKM2, LDH-A and p-PDH. Concomitant suppression of PKM2 or PDK1 expression enhanced the effects of TKIs on downregulation of HKII, p-PKM2, LDH-A and p-PDH. In agreement with these findings, a parallel decrease of glucose consumption and a concomitant increase of intracellular ATP levels were observed in response to TKIs and both were enhanced by the concomitant suppression of PKM2 or PDK1 expression. **Conclusion:** Our findings indicate that selective targeting of glucose metabolism and EGFR signaling enhances TKIs effects on cell viability and reactivation of oxidative phosphorylation.

OP-400

A direct comparison of four different ⁶⁸Ga-labeled RGD peptides for PET/CT imaging of angiogenesis

D. Lobeek[1], *S. Y. A. Terry*[2], *G. M. Franssen*[1], *M. T. Ma*[3], *H. Wester*[4], *C. Decristoforo*[5], *W. J. G. Oyen*[1,6], *O. C. Boerman*[1], *M. Rijpkema*[1]; [1]*Radboud University Medical Center Nijmegen, Nijmegen, NETHERLANDS,* [2]*King's College London, London, UNITED KINGDOM,* [3]*King's College London, London, UNITED KINGDOM,* [4]*Technische Universität München, Garching, GERMANY,* [5]*Medical University Innsbruck, Innsbruck, GERMANY,* [6]*Institute of Cancer Research, Royal Marsden NHS Trust, London, UNITED KINGDOM.*

Objectives: $\alpha_v\beta_3$ integrins play an important role in angiogenesis and cell migration of tumours. They are highly expressed on activated endothelial cells of newly formed blood vessels and absent at almost all normal endothelial tissue. Various multimeric cyclic RGD analogues have been developed for the *in vivo* imaging of $\alpha_v\beta_3$ integrins. Here, we present a direct comparison of the *in vivo* $\alpha_v\beta_3$ integrin targeting characteristics of four commonly used RGD peptides: ⁶⁸Ga-labeled DOTA-E-[c(RGDfK)]$_2$, TRAP-(RGD)$_3$, fusarinine-C-(RGD)$_3$, and THP-(RGD)$_3$. These peptides are tested in two different human xenograft tumour models; with and without $\alpha_v\beta_3$ integrin-expressing tumour cells. **Methods:** Balb/c nude mice were subcutaneously injected with either FaDu ($\alpha_v\beta_3$ integrin negative) or SK-RC-52 ($\alpha_v\beta_3$ integrin positive) tumour cells. The dimeric DOTA-E-[c(RGDfK)]$_2$ peptide, and the trimeric TRAP-(RGD)$_3$, fusarinine-C-(RGD)$_3$, and THP-(RGD)$_3$ peptides were labeled with ⁶⁸Ga and intravenously administered to the mice (0.5 nmol per mouse, 10-15 MBq), followed by *in vivo* imaging using the Inveon microPET/CT and *ex vivo* biodistribution studies at 1 hour post injection. Uptake was expressed as percentage injected dose per gram tissue (%ID/g). For both tumour models, the non-specific uptake of the four tracers was determined by coinjecting an excess unlabeled DOTA-E-[c(RGDfK)]$_2$ (50 nmol) along with the radiolabeled radiotracers. **Results:** All four compounds showed specific tumour uptake in both tumour models. In the SK-RC-52 tumour model mean tumour uptake of ⁶⁸Ga-fusarinine-C-(RGD)$_3$ (12.5±2.5%ID/g) was significantly higher than ⁶⁸Ga-DOTA-E-[c(RGDfK)]$_2$ (5.3±1.9%ID/g, **p**<0.0005), ⁶⁸Ga-TRAP-(RGD)$_3$ (4.4±0.8%ID/g, **p**<0.0005), and ⁶⁸Ga-THP-(RGD)$_3$ (5.3±0.6%ID/g, **p**<0.0005). However, in the FaDu tumour model significantly lower uptake of ⁶⁸Ga-TRAP-(RGD)$_3$ (1.0±0.2%ID/g) compared to ⁶⁸Ga-fusarinine-C-(RGD)$_3$ (1.9±0.3%ID/g, **p**=0.026) and ⁶⁸Ga-THP-(RGD)$_3$ (2.2±0.7%ID/g, **p**=0.002) was found. Thus, different trends in mean tumour uptake were found in the two different tumour models. Different trends were also observed when assessing the tumour-to-blood ratios (TBR): 18.6 ± 6.5, 31.5 ± 15.8, 28.2 ± 11.5, 13.5 ± 1.5, and 5.9 ± 2.6, 5.0 ± 2.5, 3.1 ± 1.2, 6.8 ± 2.8, for ⁶⁸Ga-DOTA-E-[c(RGDfK)]$_2$, ⁶⁸Ga-TRAP-(RGD)$_3$, ⁶⁸Ga-fusarinine-C-(RGD)$_3$, and ⁶⁸Ga-THP-(RGD)$_3$ in the SK-RC-52 and FaDu xenograft tumour model, respectively. Both tumour models showed similar uptake pattern of ⁶⁸Ga-DOTA-E-[c(RGDfK)]$_2$, ⁶⁸Ga-TRAP-(RGD)$_3$, ⁶⁸Ga-fusarinine-C-(RGD)$_3$, and ⁶⁸Ga-THP-(RGD)$_3$ in non-tumour tissue. **Conclusions:** ⁶⁸Ga-labeled DOTA-E-[c(RGDfK)]$_2$,

TRAP-(RGD)$_3$, fusarinine-C-(RGD)$_3$, and THP-(RGD)$_3$ all allowed imaging of α$_v$β$_3$ integrin expression in both the α$_v$β$_3$ integrin negative FaDu and the α$_v$β$_3$ integrin positive SK-RC-52 xenograft models. However, individual differences in the *in vivo* targeting characteristics of multimeric cyclic RGD analogues were observed depending on the outcome measure and the human xenograft model used.

OP-401

Synthesis and biological evaluation of novel five F-18 labelled radioligands for detection of MAO-B activity

S. Nag[1], A. Jackson[2], A. Takano[1], K. Jia[1], R. Arakawa[1], M. Jahan[1], R. Ahmad[2], S. Luthra[2], R. Maior[1], C. Halldin[1]; [1]Karolinska Institutet, Stockholm, SWEDEN, [2]GE Healthcare, London, UNITED KINGDOM.

Objective: Monoamine oxidases (MAO) are important enzymes regulating the levels of monoaminergic neurotransmitters and of bioactive monoamines by catalyzing their deamination. MAO-B inhibitors are widely used in the treatment of e.g. Parkinson's disease (PD). L-deprenyl, a MAO-B inhibitor has been labelled with ^{11}C and used in PET studies to image the distribution of available MAO-B in the human brain. Carbon-11 labelled L-deprenyl is less suitable for its relatively short half life, irreversible binding kinetics and the formation of a radiometabolite methamphetamine that can enter into the brain. In this project our aim was to develop a fast and efficient synthetic method for labeling five reversible MAO-B inhibitors (GEH200439, GEH200448, GEH200449, GEH200431A and GEH200431B) with ^{18}F and their biological evaluation for the detection of MAO-B. **Method:** All five precursors and reference standards were provided by GE Healthcare. Radiolabeling was achieved by classical one-step fluorine-18 nucleophilic substitution reaction. The reaction was carried out in DMSO at 110-145 °C for 10-30 min. The stability was determined using HPLC. All five ^{18}F-labeled compounds were tested in human whole hemisphere autoradiography (ARG) experiments. Four compounds except GEH200448 were examined by PET in rhesus monkeys and radiometabolites were measured in monkey plasma using a gradient HPLC system. In addition to the baseline PET measurements, GEH200439 and GEH200431A were examined after pretreatment with L-deprenyl (1,0 mg/kg) **Results:** All the compounds were successfully radiolabeled. The incorporation yield of the fluorination reactions varied from 10% to 45% depending on the compound. The radiochemical purity was higher than 99% for all four radioligands at the end of synthesis. Specific radioactivity was 76-232 GBq/μmol at the time of administration. Radioligands were found to be stable, with a radiochemical purity of >99% at 2h after formulation in a sterile phosphate buffered solution (pH = 7,4). Although autoradiography on human brain tissue section demonstrated specific binding for GEH200449 to MAO-B, no specific uptake was observed in monkey brain PET. However, for GEH200431A, less favorable ARG result were obtained, but pronounced specific uptake in MAO-B rich regions and blocking effect by L-deprenyl was seen in monkey PET. Radiometabolite studies demonstrated that for all of the four compounds, only polar radiometabolites were formed with 25%-35% unchanged radioligand remaining 90 min post injection. **Conclusion:** Radiolabeling of five new fluorine-18 MAO-B inhibitors was successfully accomplished. Compound GEH200431A binds specifically to MAO-B in vivo monkey brain and is a potential candidate for further investigation.

Standardization of MIBG Heart-to-Mediastinum Ratio Using a Phantom-based Calibration Method

K. Nakajima[1], K. Okuda[2], K. Yokoyama[3], T. Yoneyama[3], S. Tsuji[3], S. Tsuji[3], H. Oda[3], M. Yoshita[4], K. Kubota[3]; [1]Kanazawa University Hospital, Kanazawa, JAPAN, [2]Kanazawa Medical University, Uchinada, JAPAN, [3]Public Central Hospital of Matto Ishikawa, Hakusan, JAPAN, [4]Hokuriku National Hospital, Nanto, JAPAN.

Aim: In 123I-metaiodobenzylguanidine (MIBG) studies, a cross-calibration phantom method has shown to be applicable to any collimator types with Anger camera based on Japanese and European phantom studies. However, whether the approach of the simple conversion coefficient can be applicable to cadmium-zinc-telluride D-SPECT camera has not been examined. The aim of this study was to determine a phantom-based conversion coefficient for D-SPECT and validate the method by comparing heart-to-mediastinum ratios (HMR) by Anger and D-SPECT cameras. **Methods:** Calibration phantom experiments were performed with Anger and D-SPECT cameras using the same phantom validated in Japanese and European multicenter studies. A conversion coefficient to mathematically calculated reference value was determined and used as a basis for conversion among camera systems. A total of 40 patients (80 studies including early and late imaging) with suspected of having chronic heart failure and Lewy-body disease underwent 123I-MIBG studies with Anger camera (low-energy high resolution (LEHR) collimator) and D-SPECT. In Anger camera, anterior image was used while a planogram, which is nearly equivalent to an anterior planar image, was created and used for calculating HMR. The effect of correction of HMRs to both Anger camera with LEHR and medium-energy (ME) collimator conditions was examined. **Results:** Conversion coefficients for Anger camera with LEHR collimator and D-SPECT were 0.55 and 0.63, respectively. The original HMR from the Anger camera and D-SPECT were 1.76 ± 0.42 and 1.86 ± 0.55, respectively (p<0.0001). After D-SPECT HMR was converted to Anger camera conditions, corrected D-SPECT HMR became comparable values to Anger camera condition (1.74 ± 0.47, p = ns). Moreover, when both Anger camera with LEHR collimator and D-SPECT conditions were converted to standardized ME collimator conditions with conversion coefficient of 0.88, the HMRs became comparable (2.21 ± 0.65 vs. 2.20 ± 0.75, p=ns). When patients were classified into two groups with higher and lower HMR (≥ 1.6 and <1.6, respectively), the effect of correction is not significant with low-HMR patients. However, the main effect of correction was evident when HMR is more than >1.6, and was useful for differentiating both groups. **Conclusion:** The conversion coefficient of D-SPECT was determined and could be used to cross-calibrate HMR between two systems. The advantage of using phantom-based correction is possibility to calibrate HMRs between D-SPECT and Anger camera with any collimator types.

OP-408

Inter-study reproducibility of SPECT ^{123}I-mIBG left atrial innervation imaging for the identification of left atrial ganglionated plexi in patients with paroxysmal atrial fibrillation

J. Stirrup[1], U. Voss[2], S. Gregg[2], R. Baavour[3], N. Roth[3], C. Breault[3], S. Ernst[2], S. Underwood[2]; [1]Royal Berkshire NHS Foundation Trust, Reading, UNITED KINGDOM, [2]Royal Brompton and Harefield NHS Foundation Trust, London, UNITED KINGDOM, [3]Spectrum Dynamics Medical Ltd, Caesarea, ISRAEL.

Introduction: Outcomes following pulmonary vein isolation (PVI) in patients with atrial fibrillation (AF) may be improved by concomitant ablation of left atrial (LA) ganglionated plexi (GP). Single-photon emission computed tomography (SPECT) LA innervation imaging, using the noradrenaline analogue ^{123}I-metaiodobenzylguanidine (mIBG), identifies GP locations non-invasively but inter-study reproducibility is not yet known. We undertook serial SPECT ^{123}I-mIBG LA innervation imaging in patients with paroxysmal AF and assessed agreement for discrete ^{123}I-mIBG uptake areas (DUA). **Methods:** 10 patients undergoing PVI for paroxysmal AF underwent sequential LA innervation imaging 4 hours after injection of 370MBq ^{123}I-mIBG using a dedicated solid-state gamma camera. A second scan was acquired immediately after completion of the first acquisition. Where possible, images were reconstructed using ECG and respiratory gating. SPECT tomograms were co-registered with cardiac computed tomograms (CT) acquired clinically for delineation of LA and PV anatomy prior to ablation. DUAs were identified and marked on a standardized 32-segment left atrial segmentation map. Each DUA was assigned a confidence score (1: low; 2: moderate, 3: high) based on discreteness, extent of overlap with non-LA activity (e.g. LV myocardium, lung) and proximity to known GP locations. **Results:** 55 DUAs were identified (median per patient 6 [5.25 - 6]). 15, 17 and 23 DUAs were assigned confidence levels 1, 2 and 3 respectively. Overall, 33/55 (60%) DUAs were identified in the same left atrial segment on both studies. The level of agreement increased with reporter confidence (5/15 (33%), 9/17 (55%) and 19/23 (83%) for levels 1, 2 and 3 respectively). The likelihood of agreement was improved at the highest level of confidence in the 7 studies reconstructed with ECG and respiratory gating (3/11 (27%), 6/11 (55%) and 15/17 (88%) for levels 1, 2 and 3 respectively). **Conclusion:** ^{123}I-mIBG SPECT LA innervation imaging identifies GPs reproducibly and agreement is closely linked to reader confidence. When studies are acquired with ECG and respiratory gating, inter-study agreement exceeds 85% at the highest level of confidence, whilst low-likelihood areas of uptake - non-discrete, overlapping with other non-LA activity and in sites not typical for ganglionated plexi - are much less likely to be reproduced on serial imaging.

OP-409

Evaluation of the effectiveness of radiofrequency ablation of atrial fibrillation: a 123-Iodine-MIBG myocardial scintigraphy study

Y. Saushkina, V. Saushkin, K. Zavadovskiy, I. Kisteneva, I. Kostina, Z. Vesnina, Y. Lishmanov, S. Popov, R. Karpov; Cardiology Research Institute, Tomsk NRMC, Tomsk, RUSSIAN FEDERATION.

Purpose: The aim of the study was to identify scintigraphic predictors of the effectiveness of interventional treatment of atrial fibrillation (AF). **Methods and Materials:** In this study were enrolled 35 patients with essential hypertension (EH) (the duration of EH 5-20 years): 17 patients with persistent AF and 18 patients with long-standing persistent AF. All patients underwent single-photon emission computer tomography (SPECT) with 123I-metaiodbenzilguanidine (123I-MIBG) to evaluate cardiac sympathetic nervous system (SNS) activity before radiofrequency catheter ablation (RFCA). Evaluation

of the effectiveness of RFCA was carried out after 12 months by means of twenty-four hour Holter monitoring. **Results:** Patients of both groups were divided into subgroups depending on the presence of recurrence of arrhythmia in a year after interventional treatment. In the group of patients with persistent AF, the arrhythmia recurrence 12 months after RFCA were detected in 7 people. In the group of patients with long-standing persistent AF, the arrhythmia recurrence 12 months after RFCA were detected in 8 people. By ROC analysis identified the main scintigraphic predictors of the effectiveness of interventional treatment of AF. Were investigated the preoperative scintigraphic characteristics of cardiac sympathetic activity for which subgroups with and without AF recurrence had significant differences. Optimal thresholds for predicting the effectiveness of RFCA in patients with persistent AF was ≥1,7 for delayed heart-to-mediastinum ratios (HMR) (0,991 area under the ROC curve; sensitivity 100%, specificity 71%). Optimal thresholds for predicting the effectiveness of RFCA in patients with long-standing persistent AF were ≥1,69 for early HMR (0,849 area under the ROC curve; sensitivity 100%, specificity 62%); ≥1,66 for delayed HMR (0,938 area under the ROC curve; sensitivity 94%, specificity 23%). **Conclusion:** Thus, cardiac MIBG scintigraphy can be used to predict high risk of recurrence of atrial fibrillation after radiofrequency catheter ablation. The study was supported by a grant from the Russian Science Foundation No 15-15-10016.

OP-410

Value of Gated-perfusion SPECT, synchrony and I123-MIBG scintigraphy in predicting cardiac resynchronization therapy response

A. García-Burillo, P. Hinojosa, S. Aguadé, J. Pérez-Rodón, M. N. Pizzi, G. Cases, M. Andrés, N. Rivas, A. Moya; Hospital General Universitari Vall d'Hebron, Barcelona, SPAIN.

Background: Cardiac resynchronization therapy (CRT) is a well established treatment in patients with heart failure, LVEF≤35% and QRS≥120ms. However, approximately 30-40% of patients do not respond to this therapy. **Objective:** To assess the value of gated myocardial perfusion SPECT (GMPS), phase synchrony and ^{123}I-metaiodobenzyl-guanidine (^{123}I-MIBG) scintigraphy to predict response to CRT. **Methods:** In this prospective observational study, patients with a CRT indication were consecutively included. Prior to implantation, a GMPS and ^{123}I-MIBG scintigraphy were performed the same day, and latest phase mechanical activation site, LV scar percentage and heart-to-mediastinum ratio (HMR) assessed. We attempted lead concordance, defined as LV lead implantation in the area of latest mechanical activation assessed with phase analyses of GMPS, in all patients. CRT response was defined as an increase in LVEF≥5 percentage points or a reduction in LVEDV≥15% at 6 months follow-up. **Results:** Fifty-five patients were consecutively included (69±11 years, 82% male). Mean % of LVEF was 26±6. At 6 months follow-up, 58% of patients responded to CRT and lead concordance was achieved in 69% of patients. Patients that responded to CRT had lower LVEDV and LVESV and higher LVEF that patients who did

not respond (p<0.05). When lead concordance was achieved, 71% of patients responded to CRT, whereas when lead concordance was not achieved, only 29% responded (p=0.007). LV scar percentage was lower in patients that responded to CRT compared to patients that did not respond: 10±10 vs 25±14 (p<0.001). HMR was higher in patients that responded to CRT compared to patients that did not respond: 1.35±0.33 vs 1.26±0.12 (p=0.056). In multivariable analyses, only lead concordance (OR=51.184, 95% CI 3.503-747.990, p=0.004) and lower LV scar percentage (OR=0.880, 95% CI 0.788-0.983, p=0.024) were independent predictors of response to CRT. **Conclusions:** Concordance of LV lead implantation site with area of latest phase mechanical activation, assessed with phase analysis of GMPS can be achieved in nearly 70% of cases and predicts, as well as LV scar, response to CRT.

OP-411

Effect of resyncronization therapy on endothelial dysfunction and functional parameters in patients with chronic heart failure and left bundle branch block

T. Massardo[1], J. Pereira[2], C. G. Sáez[2], I. Aramburu[1], R. Morris[1], S. Brugère[1], A. Pino[1], E. Swett[1], E. Hiplan[1], R. Aguayo[3], R. Aguayo[3], G. Paillahueque[1], L. Alarcón[1], J. Torres[3], J. Spuler[1], R. Fernández[1], E. Sanhueza[1], M. Palominos[2], N. Olivares[2], G. Valenzuela[2], R. Asenjo[1]; [1]Hospital Clínico Universidad de Chile, Santiago, CHILE, [2]Pontificia Universidad Católica de Chile, Santiago, CHILE, [3]Hospital San Juan de Dios, Santiago, CHILE.

Introduction: Chronic heart failure (CHF) is a complex disease associated with systemic inflammation and endothelial dysfunction (ED) and its pathogenesis is not well understood. In the scope of a multicenter IAEA trial, we studied CHF patients submitted to resynchronization therapy (CRT). AIM: to evaluate a possible relationship between ED markers and CRT response, already observed with brachial artery flow-mediated dilation. **Methods:** We included 20 CHF patients with II-IV NYHA class with left bundle branch block (QRS≥120ms) and left ventricular ejection fraction (LVEF) ≤35% studied at baseline and 6 month post-CRT (mean age 64 years, 8 females). All with Minnesota Living with Heart Failure Questionnaire (MLHFQ); 6-min walking test (6-WT), ECHO-2D and rest gated sestamibi SPECT. Synctool® software was employed for mechanical synchronism. We determined ultrasensitive C-reactive protein (us-CRP); N-Terminal brain natriuretic peptide (pro-BNP); circulating endothelial cells number (CEC); soluble vascular cell adhesion molecule (sVCAM); soluble intercellular adhesion molecule (sICAM); interleukin-6 (IL-6); *von Willebrand* Factor (vWF) and RhoA/Rho Kinase (ROCK) pathway activation. Patients were classified as responders or non-responders to CRT, according to our trial criteria. Mean differences and correlations were analyzed. **Results:** At baseline, mean values were: pro-BNP 5290 pg/ml; us-CRP 1,7ug/mL; MLHFQ score 72; 6-WT 391 meters. CEC and vWF were over normal limits. Post-CRT, 50% of patients was responder: 11/20 patients increased at least 1 NYHA class and also ≥10% in their 6-WT; MLHFQ decreased (p<0.0001); LVEF and eccentricity improved (p=0.003 and 0.02,

respectively); end systolic volume and gated mass decreased (p=0.008 and 0.035, respectively); mean phase standard deviation (SD) and bandwidth (BW) did not change. Pro-BNP decreased (p=0.03) and us-CRP tended to decreased (p=ns). Summed rest score increased in non-responders (p=0.008); phase SD and BW were similar as well as eccentricity and gated mass (p=ns). In responders, the number of CEC decreased significantly from 67±37 to 51±17/mL (p=0.020) but still over normal limits (<10/mL) as compared with non-responders (p=ns). Pro-BNP, us-CRP, SVCAM, SICAM, IL-6, vWF and ROCK did not change between groups, however vWF remains increased. There was correlation between pro-BNP with 6-WT changes (r=0.617; p=0.004) and us-CRP with MLHFQ (r=0.617; p=0.004) and vWF(r=0.663; p=0.002). **Conclusion:** In patients with CHF and left bundle branch block there was evidence of marked ED expressed as increased CEC, a sensitive peripheral marker that significantly diminished 6 months post-CRT in responders, persisting in abnormal limits. Other cardiac function and inflammatory parameters correlated but not showed significant differences.

OP-412

MIBG scintigraphy to better identify patients who benefit from AICD in primary prevention

G. Bertuccio, G. Scrima; Ospedale S. Croce - ASLTO5, Moncalieri, ITALY.

Background: 1-2% of the adult population in developed countries has heart failure. In this population, mortality has been significantly reduced by the advent of ICD in primary prevention. About 80% of the ICD recipients will never experience an event requiring the appropriate intervention of the ICD. Currently doesn't exist a reliable screening test to select patients candidate to ICD implant. MIBG scintigraphy, such as in ADMIRE study, demonstrated very high negative predictive value for arrhythmic events in patients with Heart/Mediastinum ratio late > 1,6 and a good positive predictive value in patients with H/M late < 1,6. The aim of this study is to assess if the MIBGs should be useful to identify patients with HF who do not benefit from the ICD implantation for a low risk of arrhythmias and those who could procrastinate implant. **Methods:** This is a prospective study where patients undergoing MIBGs from February 2012 to December 2015. Inclusion criteria where: age ≥ 18 years old, LVEF ≤ 35% with idiopathic or ischemic heart disease, no previous documentation of malignant ventricular arrhythmias. Patients were divided in two groups based on of H/M late < or ≥1.60 on MIBGs. **Primary end-point:** mortality and malignant arrhythmias (MACE) RESULTS: 81 patients enrolled (median age: 69 years); 38 with ischemic and 43 with idiopathic heart disease. At the MIBG scintigraphy, 54 patients presented H/M late < 1.60 and 27 patients with H/M late ≥ 1.60. After a median follow-up of 13,7 (± 9,7) months, the primary end-point occurred in 17 patients out of 81; 16 out of 17 with MACE showed an H/M late <1,6. No arrhythmias occurred in patients with H/M late >1,6. Diabetes was associated with the occurrence of the primary end-point. **Conclusion:** This study shows that MIBGs exam with H/M late ≥ 1.60

is a positive prognostic factor with a very high negative predictive value (100% for arrhythmia and 96,3 for death) and with H/M late < 1.60 is a negative prognostic factor where the presence of diabetes predicts the occurrence of ventricular arrhythmias. In 16 patients with H/M late < 1,6 out of 54, occurred the primary end-point and the presence of diabetes was a predictor of the occurrence of ventricular arrhythmias. It confirms the idea that the deregulation of the autonomic system, as observed in diabetes, is fundamental in the occurrence of arrhythmias.

OP-413

The potential role of myocardial viability assessment using 18F-FDG PET-CT in patients with non-ischemic cardiomyopathy eligible for catheter radiofrequency ablation of ventricular tachycardias: preliminary considerations

S. Capitanio[1], R. Sara[2], C. Popescu[2], G. Colombo[2], S. Pedretti[2], P. Ferro[2], M. Milella[2], C. Rossetti[2]; [1]ASUITS Hospital, Trieste, ITALY, [2]Niguarda Hospital, Milano, ITALY.

Purpose: Catheter radiofrequency ablation (RFA) represents an important therapeutic option in non-ischemic cardiomyopathy (NICM) patients with recurrent episodes of ventricular tachyarrhythmias refractory to anti-arrhythmic drug therapy. This approach is even more relevant in NICM patients with impiantable cardiac device (ICD) and frequent painful discharges. Recently, several mapping systems have been introduced to facilitate RFA procedures. The CARTO electroanatomic mapping system is currently the most commonly used tool and it can provide three-dimensional color-coded maps of impulse propagation within the cardiac chambers. Before RFA procedure, cardiac magnetic resonance imaging (MRI) with delayed enhancement represents the gold standard for the evaluation of anomalous myocardial tissue that may harbor the arrhythmia substrate. However, evaluation of myocardial viability with FDG-PET might play a role in selecting the most appropriate mapping approach in patients with contraindications to MRI (i.e presence of ICD or severe renal dysfunction). The aim of this study was to verify whether myocardial viability assessment with FDG PET-CT might be helpful in guiding RFA. **Methods:** 6 males non-diabetic patients (mean age 61 year) with NICM underwent an FDG PET-CT study at least one day before RFA procedure. In these patients MRI was contraindicated for end-stage kidney disease in one patient and for the presence of ICD in the remaining 3 patients. An oral glucose load protocol was applied at least 30 minutes before tracer injection in order to enhance myocardial glucose uptake and suppress fatty acids utilization. A cardiac PET-CT acquisition (15 minutes) started after about 45 minutes from FDG administration. The results were displayed with QPS software (Cedars-Sinai Medical Center) to estimate global and regional cardiac uptake of FDG through 17 segment polar maps. RFA was guided by the CARTO system mapping and both left ventricular bipolar potentials and unipolar voltage maps were evaluated. **Results:** In these 6 patients we found a closely match between areas with pathological voltages at CARTO mapping and those characterized by a reduction in FDG uptake. In fact, in

these patients the clinical ventricular tachycardia was induced and successfully ablated at the exit site, which was located inside the pathological area identified at CARTO. All the patients had a significant reduction of arrhythmic events up to 8 month of follow-up. **Conclusions:** These preliminary findings suggest a potential role of myocardial viability evaluation by FDG PET-CT in the identification of myocardial substrate of arrhythmia. Therefore, this imaging technique could be helpful in guiding RFA procedure.

In-vivo biokinetics of ^{177}Lu-OPS201 in mice and pigs as a model for predicting human dosimetry

S. Beykan[1], M. Fani[2], G. Nicolas[2], D. Wild[2], R. Bejot[3], J. Kaufmann[3], H. Bouterfa[3], S. Jensen[4], M. Lassmann[1]; [1]Department of Nuclear Medicine, University of Würzburg, Würzburg, GERMANY, [2]Division of Nuclear Medicine, University Hospital of Basel, Basel, SWITZERLAND, [3]Octreopharm Science GmbH, Ipsen Group, Berlin, GERMANY, [4]Department of Chemistry and Biosciences, Aalborg University, Department of Nuclear Medicine, Aalborg University Hospital, Aalborg, DENMARK.

Aim: ^{177}Lu-OPS201 is a high-affinity somatostatin receptor antagonist for Peptide Receptor Radionuclide Therapy in patients with neuroendocrine tumors. Here we report a comparison between the biokinetics in animals and in patients. In addition, five inter-species extrapolation methods were examined to find the optimal method for dosimetry. **Materials and Methods:** Data on biokinetics of ^{177}Lu-OPS201 were obtained in athymic Nude-***Foxn1***^{nu} mice (28F, weight: 26±1g),

Danish-Landrace pigs (3F-1M, weight: 28±2kg), and patients (3F-1M, weight: 61±17kg) with administered activities of 0.19-0.27MBq (mice, 0.017µg of peptide), 97-113MBq (pigs, 9µg of peptide) and 850-1086MBq (patients, 55-106µg of peptide) [1,2]. In pigs and patients, kidney protection was applied. Multiple planar and SPECT/CT scans were performed until 250h (pigs) and 70h (patients) to quantify the uptake in kidneys and liver. Blood samples were taken up to 168h (patients) and 300h (pigs). Mice were euthanized at different time points (up to 168h); the organ-specific activity contents (including blood) were measured. Population-based time-dependent uptake data sets were created for each species and organ/tissue. Bi-exponential fits were applied to compare the biokinetics of kidneys liver, and blood in each species and to analyze the differences. The time-integrated activity coefficients (TIACs) were calculated by integration of the respective data. To determine the optimal extrapolation method, several scaling methods (relative organ/whole-body mass-scaling, time-scaling, combined mass- and time-scaling, allometric scaling) were compared. Blood TIAC values of mice were not included since the data for total blood volume were not available. **Results:** A fast blood clearance of the compound was observed in the first phase (<56h) for each species. In comparison to patients, pigs show higher liver retention. Based on the direct comparison of the TIACs, an underestimation in mice (liver, kidney) and an overestimation in pigs' kidneys compared to the patient data (Kidney-TIAC: Mice=1.4h, Pigs=7.7h, Patients=5.8h, Liver-TIAC: Mice=0.7h, Pigs=4.1h, Patients=5.3h) were observed. Most similar TIACs were obtained by applying time-scaling (mice) and combined scaling (pigs) methods (Kidney-TIAC: Mice=3.9h, Pigs=4.8h, Patients=5.8h, Liver-TIAC: Mice=0.9h, Pigs=4.7h, Patients=5.3h). Other methods showed higher deviations. **Conclusion:** If the organ mass ratios between the species are high, the combined mass- and time-scaling method is optimal to minimize the interspecies differences. The analysis of the fit functions and the TIACs show that, in our study, pigs better mimic human biokinetics than mice for blood and the organs considered. **References:** [1] Beykan et al, EJNMMI Research 2016, [2] Wild et al, JNM 2014

OP-428

A comparison of 2D and 3D kidney absorbed dose measures in patients receiving Lutate therapy

K. Willowson[1], H. Ru[1], A. Singh[2], P. Jackson[3], E. Eslick[2], D. Bailey[2]; [1]University of Sydney, Sydney, AUSTRALIA, [2]Department of Nuclear Medicine, Royal North Shore Hospital, Sydney, AUSTRALIA, [3]Peter MacCallum Cancer Centre, Melbourne, AUSTRALIA.

Aim: Kidneys are considered the organ-at-risk (OAR) for ^{177}Lu-DOTATATE (Lutate) treatment. Proposed OAR dose thresholds have been imported from radiotherapy, which may not be suitable for Lutate treatment given differences in radiation type, dose rate, and heterogeneity of dose distribution. Whilst the majority of literature estimating Lutate kidney dose is based on 2D planar imaging, more accurate quantitative 3D imaging is now becoming available. The aim of this study

was to compare kidney absorbed dose measures made from 2D and 3D imaging in patients receiving Lutate therapy, for the purpose of deriving accurate estimates of kidney dose to guide treatment. **Materials and Methods:** Patients underwent whole body planar imaging and kidney SPECT/CT at 0.5, 4, 24, and 96-120 hours after ~8 GBq Lutate injection. Transmission based attenuation correction was applied to planar data before conversion to units of absolute activity via two methods, using either a calibration standard or pre-voiding image counts. Regions-of-interest were used to generate time activity curves (TACs) and kidney doses were estimated in OLINDA. Quantitative SPECT (qSPECT) data were generated using CT-derived scatter, attenuation, and dead-time corrections and calibrated with a detector sensitivity factor. Volumes-of-interest were defined on the co-registered CT and TACs and dose estimates generated in OLINDA, both with and without correction for patient specific kidney volumes. 3D dose maps were also derived through dose kernel convolution (DKC) and CT-derived VOIs used to estimate kidney dose, which was treated as the gold standard. **Results:** 50 series were analysed. The average kidney absorbed dose was 2.6 ± 1.1 Gy/cycle (0.34 ± 0.14 mGy/MBq), based on the DKC method. 2D dose estimates were higher than DKC estimates by, on average, a factor of 2.3. There was no significant difference in 2D dose estimates made by the use of a calibration standard vs normalisation of counts to injected activity. Doses calculated using qSPECT and OLINDA were higher than DKC estimates by, on average, a factor of 1.3. The average difference between 3D dose estimates made with OLINDA using model kidney volumes vs patient specific kidney volumes was 3% (max 43%). **Conclusion:** Centres using 2D planar estimates for Lutate kidney absorbed dose can expect to overestimate the true exposure and should be cautious if limiting treatment cycles based on such measures and the current OAR thresholds. 3D estimates are likely to be more accurate in guiding further Lutate cycles and understanding true kidney dose-toxicity profiles for radionuclide therapy.

OP-429

Patient-specific pharmacokinetics and dosimetry over multiple therapy cycles during ^{177}Lu-based radionuclide therapy: a study for ^{177}Lu-DOTATATE and ^{177}Lu-PSMA

A. Gosewisch, L. Ermoschkin, H. Ilhan, A. Todica, L. Vomacka, P. Bartenstein, G. Böning; University Hospital Munich, Munich, GERMANY.

Aim: Both, ^{177}Lu-DOTATATE and ^{177}Lu-PSMA, evolved as promising therapy options in case of metastasized cancer disease. The aim of this work was to study ^{177}Lu-DOTATATE and ^{177}Lu-PSMA with regard to the patient-specific pharmacokinetics over multiple therapy cycles and to derive appropriate image-based dosimetry schemes. **Methods:** The kidney and tumour pharmacokinetics of 12 patients (6: 3.7-6GBq ^{177}Lu-PSMA-DKFZ-617, 6: 7.4GBq [[177]Lu-][DOTA[0]][Tyr[3]]Octreotate) was studied over the initial two therapy cycles via quantitative SPECT acquired 24, 48 and 72h p.i. (+CT). For each patient and cycle, both kidneys and three tumours were delineated and a corresponding S-value

dosimetry including a mono-exponential fit of the three data points was performed. Furthermore, for the dosimetry of the second cycle, we compared the doses derived from a modified imaging protocol, which combines a single SPECT either 24, 48 or 72h p.i. with the effective half-life of the first cycle. **Results:** For ^{177}Lu-DOTATATE the kidney mean (+/-SD) doses were 0.84+/-0.33Gy/GBq and 0.80+/-0.35Gy/GBq for cycle one and two. The dose increased in 25% of the kidneys due to an increased half-life, uptake or both. The tumour doses decreased from 4.92+/-4.01Gy/GBq to 3.91+/-1.94 Gy/GBq due to a reduction of the absorbed doses in 44% of the tumours, which is linked to a decrease in the effective half-life, uptake or both in 38% of the cases and partially due to an increase in the delineated tumour volume in 62% of the cases (40%-isocontour). For ^{177}Lu-PSMA the mean kidney doses were 0.58+/-0.23Gy/GBq and 0.61+/-0.21Gy/GBq for cycle one and two, with an increase of the dose for 50% of the kidneys mainly due to an increased uptake at 24h. The mean tumour dose decreased from 4.97+/-5.13Gy/GBq to 1.82+/-1.30Gy/GBq with a dose reduction in 83% of the tumours, mostly due to a decreased effective half-life partially accompanied by a decreased uptake. Although, a pronounced change of the effective half-lives is possible (^{177}Lu-DOTATATE: kidneys: 22+/-11%, tumours: 42+/-41%; ^{177}Lu-PSMA: kidneys: 14+/-13%, tumours: 29+/-23%), a dosimetry during the second cycle based on a single SPECT 72h p.i. reproduced all doses on average within 10%. **Conclusion:** Summarized, for both ^{177}Lu-DOTATATE and ^{177}Lu-PSMA , the first cycle constitutes the more importent contribution to the tumour dose and to the kidney dose for more than half of the cases. Using a reduced dosimetry scheme for the second cycle based on a single image acquisition 72h p.i. is thus feasible for both therapies.

OP-430

The effect of the total tumour volume on the kidneys, salivary glands and tumour BEDs for ^{177}Lu-labelled PSMA ligands

N. J. Begum[1], *A. Thieme*[2], *J. Allmann*[2], *M. Eiber*[2], *A. J. Beer*[3], *G. Glatting*[1], *P. Kletting*[1]; [1]*Medical Radiation Physics, Department of Nuclear Medicine, Ulm University, Ulm, GERMANY,* [2]*Department of Nuclear Medicine, Klinikum Rechts der Isar der Technischen Universität München, Munich, GERMANY,* [3]*Department of Nuclear Medicine, Ulm University, Ulm, GERMANY.*

Purpose: To investigate the effect of the total tumour volume on the tumour, kidneys and salivary glands biologically effective dose (BED) for prostate specific membrane antigen (PSMA) labelled with ^{177}Lu using a physiologically-based pharmacokinetic (PBPK) model. **Materials and Methods:** Eight patients with metastasized prostate cancer were included in this simulation study. An average activity of (7.2±0.3) GBq and ^{177}Lu-labeled PSMA-specific peptides of (87.7±4.1) nmol were administered. The individual parameters of the PBPK model were obtained from fits to measured biokinetic data. The biokinetics of every patient were simulated for total tumour volumes of 0.1, 0.3, 1, 3, and 10 l. Based on these simulations, the BED values were obtained

for two tumour lesions, the remaining tumour, the kidneys and the salivary glands. Furthermore, the therapeutic indices of tumours to organs at risk were calculated for every simulated total tumour volume. **Results:** The average BED values of these eight patients were (23 ± 13)Gy, (5.7 ± 2.2)Gy$_{2.5}$ and (13.9 ± 5.2) Gy$_{7.5}$ for lesions, kidneys and salivary glands, respectively. The simulated BEDs of the tumour lesions strongly depend on the total tumour volume, i.e. (28 ± 17)Gy, (26 ± 15)Gy, (22 ± 11)Gy, (15.3 ± 7.1)Gy and (7.6 ± 3.4)Gy for total tumour volumes of 0.1, 0.3, 1, 3, and 10 l, respectively. A similar dependence on tumour volume is obtained for the kidneys and salivary glands, i.e. (7.1 ± 3.2)Gy, (6.7 ± 2.9)Gy, (5.6 ± 2.1)Gy, (4.0 ± 1.2)Gy, (2.2 ± 0.7) Gy and (17.0 ± 7.3)Gy, (16.1 ± 6.6)Gy, (13.8 ± 4.9)Gy, (10.1 ± 3.2)Gy, (5.5 ± 2.1)Gy, respectively. The therapeutic indices have broad distributions for lesions to kidneys (median 3.9, range 0.2-9.5) and for lesions to salivary glands (median 1.6, range 0.1-6.3). The same applies for the relative change of the therapeutic index with increasing (simulated) tumour volumes: the mean change is 0 %, but in individual patients it could decrease or increase by up to 20 %, demonstrating the importance of the actual tumour volume for optimizing the treatment planning for an individual patient. **Conclusion:** The tumour and organ at risk BEDs are strongly affected by the total tumour volume for patients with advanced prostate carcinoma. The simulation study shows that patients with high tumour burden would benefit from higher prescribed activities as the BEDs to the critical organs and tumours are considerably lower compared to patients with lower total tumour volume. Therefore, an accurate method to identify the total tumour volume needs to be developed to be able to determine the optimal amount of peptide and activity for each patient.

OP-431

Concurrent use of ^{90}Y, ^{177}Lu and [225]Ac-labelled PSMA-binding radiopharmaceuticals can lead to improved treatment efficacy

A. M. Denis-Bacelar, A. J. Fenwick, K. M. Ferreira, J. L. Wevrett, A. P. Robinson; National Physical Laboratory, Teddington, UNITED KINGDOM.

Aim: Radiolabeled PSMA-based radiopharmaceuticals such as ^{90}Y-PSMA-J591, ^{177}Lu-PSMA-617 and [225]Ac-PSMA-617 have been shown effective for the treatment of metastatic prostate cancer. However, the different physical characteristics of the radionuclides are likely to have a significant impact upon the success of systemic treatments of microscopic metastases. The relationship between the tumour control probability (TCP) and tumour size was studied for different activity concentrations and combinations of ^{90}Y, ^{177}Lu and [225]Ac. **Materials and Methods:** Metastatic lesions were modelled as spheres with radii ranging from 100 μm to 2 cm. The radionuclides were assumed to be uniformly distributed through the volume. The EGSnrc general purpose Monte Carlo code was used to calculate the energy deposited by the beta emitters ^{90}Y and ^{177}Lu using the decay data from the RADTABS software. An equilibrium dose constant of 14.3 Gy·g/MBq/h and a relative biological effec-

tiveness (RBE) factor of 5 were used for the alpha emitter ^{225}Ac. Absorbed doses were calculated for a range of specific cumulated activities (MBq·h/g) and cocktail proportions of the three radionuclides. The TCP was calculated using the liner quadratic model and radiobiological parameters characteristic of prostate cancer cells: clonogenic cell density of 3.10^6 cm^{-3}, α/β of 3.1 Gy, α of 0.15 Gy^{-1} and repair constant μ of 0.46 h^{-1}. **Results:** Optimal tumour control for ^{90}Y, ^{177}Lu and ^{225}Ac as non-concurrent treatments was achieved for tumour radii larger than 0.1 cm, between 0.06 and 0.1 cm, and smaller than 0.07 cm, respectively. A TCP>0.95 was obtained for tumour sizes between 100 μm and 2 cm for a specific cumulated activity of 300 MBq·h/g and a 1:39 ratio of ^{225}Ac:^{90}Y. A higher specific cumulated activity of 1200 MBq·h/g and a 1:9 ratio of ^{177}Lu:^{90}Y was required to obtain a TCP of 0.75-0.95 for radii below 0.05 cm and a TCP >0.95 for larger tumours. **Conclusion:** The combination of ^{225}Ac and ^{90}Y resulted in improved curability of microscopic and macroscopic metastases as compared to ^{177}Lu and ^{90}Y. The concurrent use of cocktails of radiopharmaceuticals can lead to improved treatment efficacy for patients with metastatic prostate cancer. Future work will include non-uniform uptake distributions to study the effect of in-homogeneities and the effect of combining radiopharmaceuticals with different targeting mechanisms.

OP-432

Assessing the impact of registration methods on absorbed dose calculation in Peptide Receptor Radionuclide Therapy

S. Berenato¹, E. Grassi², F. Fioroni², D. Finocchiaro²,³, M. Iori², E. Spezi¹; ¹*School of Engineering, Cardiff University, Cardiff, UNITED KINGDOM,* ²*Arcispedale Santa Maria Nuova - IRCCS, Reggio Emilia, ITALY,* ³*Department of Physics, University of Bologna, Bologna, ITALY.*

Introduction: Peptide Receptor Radionuclide Therapy (PRRT) is currently the most effective therapy for the treatment of patients with Neuro-Endocrine Tumours. To determine the cumulated activity in volumes of interest (VOIs), serial measurements of the radiopharmaceutical activity should be performed through the analysis of multiple quantitative functional imaging. Sequential tomographic scans should be co-registered so that an accurate patient specific 3D dosimetry can be carried out. The rigid alignment between scans assumes that organs are only subjects to roto-translational movements and are unable to account for the complex internal organs motion present in the abdominal region. To accurately estimate the dose delivered to the VOIs, deformable image registration (DIR) is needed. This study focusses on developing an optimised workflow for the use of DIR algorithms in the context of a clinical trial in PRRT. **Materials and Methods:** Twenty patients treated with PRRT were imaged five times, post-injection of therapeutic administration of ^{177}Lu-labeled peptides with a SPECT/CT scanner. Sequential quantitative functional scans were registered to the reference scan and used to calculate patient specific 3D dose map using the Raydose Monte Carlo code[1]. We systematically

evaluated the impact of two different workflows involving a DIR algorithm. In the activity registration workflow (ARW), the activity maps were registered to the same reference scan before the total dose was calculated. In the dose registration workflow (DRW), the activity scans were used to calculate intermediate dose maps that were subsequently accumulated to obtain the total dose map using the deformation maps generated for the ARW. The accuracy of the DIRs was quantified using the Dice Similarity Coefficients (DSC) calculated for VOIs manually drawn on all scans. **Results:** DSC analysis confirmed excellent quality of the DIR maps, with DSC values > 0.7 in all cases. In 91% of patients, mean dose to organs at risk (OARs) calculated with DRW was higher than that calculated with ARW. The use of effective decay constants reduced this discrepancy in 16% of the cases. For lesion dosimetry, no correlation was found between total dose and registration algorithms, with percentage differences in the range [-44%, 50%]. **Conclusions:** Dose registration overestimates the absorbed dose to OARs compared to activity deformation and results in a more time-consuming workflow. The accuracy of lesions dosimetry is hampered by internal organ motion and remains a challenge that could be addressed by developing dedicated DIR strategies. **References:** [1] Marcatili Phys Med Biol. 2013 Vol 58 p 2491

OP-433

Evaluation of the Correlations Between the Absorbed Bone Marrow Dose and Bone Marrow Response During the First Cycle of 177Lu-DOTATATE Treatment

L. Hagmarker¹, J. Svensson², T. Rydén¹, B. Wängberg³, A. Sundlöv⁴, K. Sjögreen Gleisner⁵, P. Bernhardt¹; ¹*institution of clinical sciences, Göteborg, SWEDEN,* ²*Department of Oncology, Göteborg, SWEDEN,* ³*Department of Surgery, Göteborg, SWEDEN,* ⁴*Department of Oncology, Skåne University Hospital, Lund, SWEDEN,* ⁵*Department of Radiation Physics, University of Lund, Lund, SWEDEN.*

Treatment with ^{177}Lu-DOTATATE has become an established treatment option with minor side effects for patients with advanced neuroendocrine tumours. The bone marrow is one of the organs at risk and blood samples are drawn to monitor the bone marrow function during treatment. The aim of this project is to investigate if a correlation between the absorbed bone marrow dose and the bone marrow response in terms of decreased levels of haemoglobin, white blood cells and platelet counts can be established from the first treatment cycle. **Materials and Methods:** 35 patients with advanced neuroendocrine tumours treated with ^{177}Lu-DOTATATE at Sahlgrenska University Hospital between 2011 and 2016 (ILUMINET-study, EUDRACT nr 2011-etc) was included in this study. Blood samples were drawn once a week and absorbed doses to the bone marrow were calculated after the first treatment cycle. The absorbed bone marrow dose was estimated using planar gamma camera images collected at 2, 24, 48 and 168 hours post injection and a two-compartment method in the image platform PhONSAi, developed in-house. Correlations are investigated between the absorbed bone marrow doses and the nadir values and the response rates of haemoglobin, white blood cells and throm-

bocytes. The response rate is the linear slope calculated using blood values normalized to the baseline values. **Results:** The mean absorbed bone marrow in the first treatment cycle was estimated to 0.19 Gy (0.12-0.32 Gy). Already after the first treatment cycle significant correlations were found between the absorbed bone marrow dose and the decrease in platelet counts (p=0.02) and between the absorbed bone marrow dose and the response rate of platelet counts (p=0.01) and white blood cells (p=0.01). **Conclusion:** Significant correlations were found after the first treatment cycle between the absorbed bone marrow dose and the response of platelet counts and white blood cells. As a consequence of the slow response of haemoglobin, no correlations to the absorbed bone marrow dose could be found this early after treatment.

OP-434

Prospective Dosimetry and Optimization of RPT-XRT Combination Therapies

R. F. Hobbs, A. Josefsson, E. C. Frey, S. A. Terezakis, C. Meyer, D. M. Loeb, G. Sgouros; *Johns Hopkins University, Baltimore, MD, UNITED STATES OF AMERICA.*

Objectives: Metastatic osteosarcoma is a cancer of adolescents and young adults which has a very low survival rate. In general, disseminated disease requires systemic treatment, while for the localized macroscopic disease external beam radiation therapy (XRT) is a viable treatment option. At the same time, XRT is limited by adjacent normal organ toxicity, while radiopharmaceutical therapy (RPT) often has a high signal to background ratio locally. Moreover the two modalities are radiation-based, meaning that they can be combined rationally and treatment planning can be optimized based on the combined absorbed dose (AD) to the dose limiting organ(s). For metastatic osteosarcoma ^{153}Sm-EDTMP, an FDA approved bone seeking calcium mimetic, was combined with XRT for safe and effective therapy. **Methods**: Five patients have been treated thus far under this protocol. The patients underwent stem cell harvesting, then received a 37 MBq/kg pre-therapeutic dose of ^{153}Sm-EDTMP and were imaged at 4, 24 and 48 h p.i. The in-house RPT treatment planning system, 3D-RD, was used to optimized the combined plan of administered activity and XRT treatment plan by entering the RPT AD-map converted to 2-Gy equivalent AD (EQD2) into the XRT treatment planning system (Pinnacle). One week after the pre-dose, the therapeutic dose was administered, and the patients imaged at 4, 24 and 48 h p.i. AD-maps and DVHs were again generated using 3D-RD for the RPT portion of the treatment. A revised combined RPT/XRT treatment plan that incorporated the therapeutic Sm-153 dose deposition was created. **Results**: The plans gave therapeutic doses to target tumors. As an example for a pelvic tumor, the EQD2 delivered to the tumor by RPT was 19.9 Gy using an injected activity of 370 MBq/kg determined by the treatment plan as well as an XRT plan that delivered another 50.9 Gy to the tumor, resulting in a total tumor AD of 70.8 Gy. The AD to adjacent spinal cord from the combined treatments was 30.9 Gy, lower than the maximum tolerable AD of 52 Gy. the tumoricidal threshold dose of 70 Gy

would not have been possible with XRT alone. **Conclusions**: The treatment planning protocol combining RPT and XRT for metastatic osteosarcoma in pediatric patients has shown potential to treat a highly aggressive disease, while limiting the AD to normal organs to below potentially toxic thresholds. Based on the methodological success of this case other RPT-XRT combination therapies have been developed.

M2M: Automation & Production

OP-435

A 3D-Printed Automated Dual Reactor Synthesizer for Challenging Multi-Step ^{18}F-Fluorinations: Testing and Validation

A. Amor-Coarasa, J. M. Kelly, D. Kim, W. Qu, P. Kothari, J. W. Babich; *Weill Cornell Medical College, New York City, NY, UNITED STATES OF AMERICA.*

Aim: Robust, automated ^{18}F-fluorinations are vital for PET radiopharmacy production. Most automated synthesis units (ASU) are optimized for routine production of ^{18}F-FDG, the main PET tracer in clinical use. Despite the wide variety of ^{18}F imaging agents developed, production at radiopharmacies almost invariably requires adapting the new synthesis to an existing ASU. Versatile, customizable options for challenging multi-step syntheses such as the TRASIS ALLINONE™ are available, but at a very high cost. Hence, we sought to design and build a reliable, lower cost, fit-for-purpose, 3D-printed ASU capable of preparing ^{18}F imaging agents using multistep syntheses incorporating two reactors. **Methods:** All designs were drawn using Autodesk® AutoCAD® 2013 or newer. The housing was printed in poly(acrylonitrile butadiene styrene) (ABS). Moving parts were printed in nylon and heaters were printed in porcelain. High torque motors and linear actuators were used for valve turning and syringe loading/dispensing. A 24 channel USB servo controller was used for sequenced automation. The synthesis sequence was designed and uploaded onto the ASU via USB. Synthesis of the tracers consisted of (1) ^{18}F capture, elution and azeotropic drying; (2) synthesis of 2-^{18}F-fluoroethylazide at 80°C; (3) distillation of the synthon at 130°C and its trapping in a second reactor cooled to 5°C; and (4) a click reaction at 100°C following addition of Cu$^+$ and the alkyne precursor. **Results:** The total cost of design and assembly of the ^{18}F ASU was less than 5000 USD, a substantial improvement over the 100,000-200,000 USD that these units normally cost. Critical synthetic steps are controlled by a simple external push button, with several, sequential safety checkpoints. The synthesizer was validated for the synthesis of ^{18}F-RPS-040, a PSMA-targeting radiotracer. Decay-corrected radiochemical yield at the end-of-synthesis was 15.3±1.0% (n=3). There was no mechanical failure during any of the pre-testing sequences or validation runs (n>10). Synthesis time was 58 minutes after receiving ^{18}F from the cyclotron.

Conclusions: A 3D-printed, two reactor ASU was designed, manufactured and tested for a specific, multistep radiosynthesis that includes a distillation. The ASU is robust and reliable for routine clinical use, as neither leakage of liquids nor loss of radioactivity was observed even with high starting activities. Not only is the 3D-printed ASU a practical, lower-cost alternative to commercially available units, but it also represents a change of paradigm: *Do not adapt your synthesis to an existing ASU, but rather build a new ASU to accommodate your synthesis.*

OP-436

Optimization of a Novel Automated Loop Method for Production and Development of Analytical Methods for ^{11}C-Nicotine Injectable

K. Kumar, A. Ghosh, K. Woolum, M. V. Knopp; The Ohio State University, Columbus, OH, UNITED STATES OF AMERICA.

Objectives: The objective of the present study was to develop and optimize a novel automated loop method for production of ^{11}C-Nicotine Injectable and to develop analytical test methods (Identification, pH, Radionuclidic Purity, Radiochemical Purity (RCP), Chemical Purity, Specific Activity, Bacterial Endotoxin, and Sterility) and specifications for its quality control. **Methods:** In the automated production process, the ^{11}CO$_2$ was trapped at -180ºC, converted into ^{11}C-Methane and then ^{11}C-Methyl Iodide, followed by the reaction of ($\pm$) Nornicotine in the loop. The reaction mixture was purified using a semi-preparative Reversed-Phase (RP) HPLC method to remove unreacted ^{11}CH$_3$I and ($\pm$) Nornicotine. The final product was tested for the identification, RCP, chemical purity, and specific activity of ^{11}C-Nicotine by using an analytical HPLC method. The analytical HPLC method involved a Waters XTerra C$_{18}$ column (150x4.6 mm, 5 µm) at 40ºC with an isocratic mobile phase containing 80:20 mixture of 6.5 mM ammonium acetate pH 10 and acetonitrile at a flow rate of 1.0 mL/min. General methods (USP <71> and USP <85>) were used for Sterility and Bacterial Endotoxin tests, respectively. **Results:** A gas-phase produced ^{11}CH$_3$I precursor was used instead of ^{11}C-Formaldehyde or ^{11}CH$_3$I produced by the Lithium Aluminum/HI method. The reaction conditions were optimized by varying the amounts of precursor, loop temperature, and reaction times. These experiments suggested that the reaction of 2 mg precursor with ^{11}CH$_3$I for 5 minutes at 75^0, 100º, and/or 125ºC loop temperature gave ~20% (corrected) yield of the final product. An analytical HPLC method (with a 10 minutes run time) was developed with an excellent separation (retention times in min in the parenthesis) between ^{11}CH$_3$I (2.4), ($\pm$) Nornicotine (3.1), and ^{11}C-Nicotinine (5.5). Typically, ^{11}C-Nicotine (3.7mCi/mL) was produced with >99.9% RCP, no ^{11}CH$_3$I, no ($\pm$) Nornicotine, 9.8 ng/mL of Nicotine resulting 60.3Ci/µmole specific activity, 7.0 - 7.2 pH, and 20% ethanol. The product was also passed the Identification, Radionuclidic Purity, Sterility, and Bacterial Endotoxin tests. **Conclusions:** A robust and efficient process for production of high purity (>99.9%) ^{11}C-Nicotine with ~20% (corrected) yield was developed. Several analytical test methods and specifications for the quality control of ^{11}C-Nicotine were developed successfully.

OP-437

Synthesis Of 64Cu Radiopharmaceuticals For Cell Radiolabelling Using Anion Exchange Column And Labelling Of WBCs

A. Socan[1], P. Kolenc Peitl[1], M. Kroselj[1], M. Petrik[2], C. Decristoforo[3]; [1]Nuclear Medicine Department, University Medical Centre, Ljubljana, SLOVENIA, [2]Institute of Molecular and Translational Medicine, Olomouc, CZECH REPUBLIC, [3]University Clinic for Nuclear Medicine, University for Medicine, Innsbruck, AUSTRIA.

Introduction: ^{111}In labelled radiopharmaceuticals are extensively used for cell radiolabelling in routine clinical practice. Due to its half life (12.7 h) and positron emission ^{64}Cu labelled cells could possibly enable PET "in vivo" cell tracking with several attractive clinical applications (imaging of infection and inflammation, stem cell therapy). The aim of this study was to prepare (using an approach of synthesis and concentration on an anion exchange column) ^{64}Cu tracers (oxine, tropolone) and label WBCs. **Materials and Methods:** Small volumes (1-2 mL) of ^{64}Cu tracers (oxine, tropolone) in PBS of suitable radiochemical purity (n-octanol extraction) and activity (up to 102 MBq) were prepared on the anion exchange column (SepPAK QME) using a previously described method used for ^{68}Ga and ^{89}Zr labelling. WBCs were radiolabelled using modified (incubation time 20 min) EANM recommended ^{111}In-oxine WBCs labelling method. Labelling efficiency, cell viability, assessed by Trypan Blue exclusion assay and labelling stability (efflux of radioactivity) was determined at different time points after ^{64}Cu tracer radiolabelling. **Results:** Using an anion exchange column, synthesis and concentration method yield of ^{64}Cu-tropolone solution was above 92.5% with pH between 6.9-7.4 and extraction into octanol above 89.1%. Yield of ^{64}Cu-oxine solution was between 55-91.1% with pH between 6.9-7.5 and extraction into octanol above 90.6%. Labelling efficiency of WBCs s with ^{64}Cu-tropolone was above 81.1% and not dependent on the amount of cells available for radiolabelling. Labelling efficiency of WBCs s with ^{64}Cu-oxine was up to 68% and dependent on the amount of cells available. Viability of ^{64}Cu-tropolone radiolabelled WBCs before and immediately after the labelling was 92% and 85%, respectively; viability 240 min after labelling was 88 and 81%. Labelling stability of WBCs 240 min after cell radiolabelling was above 68% and remained constant up to 48h after labelling. Viability of ^{64}Cu-oxine radiolabelled WBCs immediately after the labelling was 71% (90% unlabelled WBCs) and 70% 240 min after labelling (85% unlabelled WBCs). Labelling stability of WBCs 240 min after cell labelling was above 91% but decreased to 78.1% 48h after labelling. **Conclusions:** The applied on-column synthesis and concentration method enables formation of ^{64}Cu tracers (oxine, tropolone) with good yields, quality and in small volumes suitable for cell radiolabelling. ^{64}Cu tracers radiolabel WBCs with sufficient stability and viability, this way making this approach highly promising for routine clinical use. Proof of concept in animal infection models is ongoing.

OP-438

Production and Purification of 99mTc Pertechnetate from 100Mo Targets Irradiated in a Nirta Solid Target Station on an IBA Cyclone® 18 Cyclotron

K. Buckley[1], P. Martini[2,1], M. Dodd[1], S. McDiarmid[1], V. Hanemaayer[1], B. Hook[1], J. Kumlin[1], S. Zeisler[1], P. Schaffer[1], C. Marshall[3], A. Dabkowski[3], M. Talboys[3], S. Wiltshire[3], F. Devillet[4], D. Blampain[4], B. Nactergal[4]; [1]TRIUMF, Vancouver, BC, CANADA, [2]University of Ferrara, Ferrara, ITALY, [3]Wales Research and Diagnostic PET Imaging Centre, Cardiff, UNITED KINGDOM, [4]IBA RadioPharma Solutions, Louvain-la-Neuve, BELGIUM.

Direct production of the highly utilized radioisotope 99mTc is a practical approach to self-sufficiency of supply. A TRIUMF-led consortium developed 100Mo coating technology to manufacture high current targets (Schaffer et al., J Nucl Med 2015; 56 Supp. 3: 164) and demonstrated the routine production and purification of 99mTc. The aim of this work is to implement these processes on an IBA Nirta target station and Synthera® Extension automated synthesis units. The project was implemented as discrete activities due to the geographical spread of the participants. At TRIUMF 100Mo pellets of 0.9 grams and 12.4 mm diameter were pressed and sintered. Using the method described in Zeisler et al. (http://www.qucosa.de/recherche/frontdoor/?tx_slubopus-4frontend[id]=16606) these pellets were bonded to copper alloy backings sized to fit the Nirta target station. At the Cardiff IBA Cyclone® 18 facility three targets were irradiated at 50 µA and 18 MeV for one hour and three for six hours. Target yields were estimated by measuring the whole target plate in a dose calibrator to obtain a decay curve from which the 99mTc component was extracted. At TRIUMF, separation and purification of 99mTc from 100Mo was carried out using two IBA Synthera® Extension modules. Each unit provides one syringe pump and ten pinch valves. The separation and purification scheme follows that published by Bénard et al (J Nucl Med 2014; 55:1910-1914). Initial testing used a mock solution of a dissolved target with no radioactivity. Parameters were adjusted to minimize the molybdenum content in the final product as measured by colorimetric test strips (LaMotte). When process parameters were optimized the mock dissolved target solution was spiked with 99mTc obtained from a generator. The target appearance was unaffected by irradiation. The decay curve analysis showed 13.5 ± 1.4 GBq of 99mTc for the one hour irradiation and 63 ± 6 GBq for the six hour irradiation, both corrected to EOB. These values are lower than the predicted values of 19 and 87 GBq, respectively, as they do not take into account geometric and self-shielding factors. In the purification tests, molybdenum content of the purified mock target solution was < 0.5 ppm while the mock solution spiked with 99mTc gave a purification efficiency of 98 %. In conclusion, an IBA Cyclone® 18 equipped with a Nirta solid target station and two Synthera® Extension automated synthesis units can produce and purify up to 60 GBq of 99mTc pertechnetate in a single 6 hour irradiation.

OP-439

Cyclotron production and automated new 2-column processing of [68Ga]GaCl3

M. Nair[1], S. Happel[2], T. Eriksson[1], M. K. Pandey[3], T. R. DeGrado[3], K. Gagnon[1]; [1]General Electric, Uppsala, SWEDEN, [2]Triskem, Bruz, FRANCE, [3]Mayo Clinic, Rochester, MN, UNITED STATES OF AMERICA.

Purpose/Introduction: Challenges with existing chemistry for separating 68Ga from bulk 68Zn include, high HCl concentration/volume and/or use of organic solvents/HBr, a further increase in HCl concentration if using a second column for 68Ga concentration, base-mediated pH adjustment, the use of non-commercial resins, etc.[1,2,3] With ongoing efforts towards cyclotron-based 68Ga separation and labelling using a FASTlab synthesis unit, this work describes a new two-column scheme to Ga/Zn separation that avoids many of the above noted challenges. **Methods:** Cyclotron-based 68Ga is produced by irradiating a solution of enriched (98.33%) 68Zn(NO3)2 in ~0.2 N HNO3.[1] The irradiated 2mL target volume is transferred ~50 meters to a receiving vessel and diluted to 5mL with water. The 68Ga is trapped on hydroxamate resin[2] (2mL [~700mg] ZR resin), washed with 14mL 0.1 N HNO3 and eluted as [68Ga]GaCl3 in 5mL 1.4 N HCl. The eluate is then efficiently trapped on TK200 resin (2mL [~700mg]) without the need for first increasing the HCl concentration. Finally, after purging with nitrogen, the trapped [68Ga]GaCl3 is eluted in 3mL water. **Results:** To highlight the current status, we report on three consecutive 68Ga runs performed on a PETtrace cyclotron with 1 M 68Zn-zinc nitrate at 14.0 MeV/60 min/26 µA optical post-grid irradiation current. After target transfer and automated separation chemistry, we obtained 68 ± 4 mCi (24 ± 2 mCi/mL) [68Ga]GaCl3 in "hand" at 30 minutes post-EOB and report a 77 ± 2% decay corrected separation efficiency. Select QC measurements include half-life (67.6 ± 0.2 min), pH (0.5), iron/zinc (<10 µg/GBq), RCP (99 ± 1%), and RNP @ EOB (99.8821 ± 0.0004%). **Discussion/Conclusion:** We have developed a new 2-column approach to isolate cyclotron-based [68Ga]GaCl3 on a FASTlab platform with recovered 68Ga radioactivity on par with current 68Ge/68Ga generators. The noted scheme eliminates base-mediated pH adjustment, it uses water to elute the final [68Ga]GaCl3, it uses only commercially available hydroxamate and TK200 resins, and it houses all reagent vials within a standard FASTlab cassette manifold (including those needed for column conditioning) while leaving adequate space for subsequent labelling on the same cassette. Optimization is underway to increase the separation efficiency and further reduce processing time prior to on-cassette labelling. While the efforts presented are on a liquid 68Zn target, it is anticipated that this process can be readily adapted to a solid target system. **References:** 1. Am J Nucl Med Mol Imaging 2014;4:303 2. WTTC 2016 Proceedings (http://wttc.triumf.ca):10 3. Nucl Med Biol 2015;42:842

OP-440

Fully automated GMP-compliant single-step synthesis of 18F-PSMA-1007 using SPE-cartridge purification

O. C. Neels[1], R. Martin[2], J. Cardinale[1], R. Smits[2], M. Schäfer[1], A. Hoepping[2], M. Müller[2], K. Kopka[1]; [1]German Cancer Research Center, Heidelberg, GERMANY, [2]ABX advanced biochemical compounds, Radeberg, GERMANY.

Aim: In recent years several radiofluorinated ligands targeting the prostate-specific membrane antigen (PSMA) have been reported [1,2]. Our aim was to optimize the two-step synthesis procedure of 18F-PSMA-1007 [3] towards a simplified and automated single-step synthesis, thereby fulfilling GMP compliance. **Materials and Methods:** A labelling precursor for direct nucleophilic substitution using trimethylammonium as leaving group has been developed. After azeotropic drying of [18F]fluoride using tetrabutylammonium hydrogen carbonate solution as base, the fully automated radiosynthesis of 18F-PSMA-1007 has been conducted on several commercially available automated radiosynthesizers (GE TRACERlab FX FN, MX and FASTLab, ORA Neptis Plug and RS, IBA Synthera) using 1.5 to 3.0 mg of precursor in DMSO for 10 minutes at 85 °C. The crude reaction mixture was taken up in water containing sodium ascorbate and trapped on pre-conditioned sequenced SPE cartridges (Chromafix PS-H+ and Chromafix C18ec, Macherey-Nagel). After rinsing with 5% EtOH solution, the purified product was eluted from the cartridges with 30% EtOH solution and diluted with 0.9% NaCl solution containing sodium ascorbate. After sterile filtration, quality control for 18F-PSMA-1007 was performed according to specifications set in compliance with current pharmacopoeias. **Results:** 18F-PSMA-1007 could be obtained in radiochemical yields ranging from 30-50% and radiochemical purities > 90 % in a total synthesis time of < 60 min in dependence of the type of radiosynthesizer (GE TRACERlab FX FN, MX and FASTLab, ORA Neptis Plug and RS, IBA Synthera) synthesis module used. No radiolysis of the product has been observed up to 8 hours after final batch formulation (40 GBq in 20 mL saline solution). **Conclusion:** A GMP-compliant radiosynthesis and quality control of 18F-PSMA-1007 using direct radiofluorination including a simplified purification procedure have been established on a wide range of commercially available radiosynthesizers (GE TRACERlab FX FN, MX and FASTLab, ORA Neptis Plug and RS, IBA Synthera). The product is obtained in good radiochemical yields with satisfying batch productions covering the daily clinical demand in a university hospital. Radiopharmaceutical quality will allow the initiation of prospective clinical trials. **References:** [1] Rowe SP *et al.*. Prostate Cancer Prostatic Dis. 2016 19(3):223-30. [2] Giesel FL *et al.*. OP-441

Automated Synthesis of Pt-195m Cisplatin for GMP Production

K. Codee-van der Schilden[1], O. Zwaagstra[1], D. van der Born[2]; [1]NRG, Petten, NETHERLANDS, [2]FutureChemistry Holding BV, Nijmegen, NETHERLANDS.

Purpose/Introduction: Imaging of the *in vivo* biodistribution of Platinum-based Cisplatin may allow to predict treatment outcome of chemo(radio)therapy in a personalized approach. We have shown the feasibility of Pt-195m SPECT imaging in mice[1], and we have adopted a known procedure[2] for the manual synthesis of Pt-195m Cisplatin for its preclinical use. To reduce synthesis time and to simplify the multistep process of the

making of Pt-195m Cisplatin, we have now developed a fully automated synthesis module, ready for GMP production. **Subjects & Methods:** First, chemical resistance of materials to *aqua regia* and concentrated hydrochloric acid was tested in a proof of concept study, and a method for the automated separation of precipitates from solution using filters was developed. Subsequently, different reaction vials, reagent vials, valves, tubing and filters were tested, and methods for dispensing, evaporation of solvents, and transfer of solutions using nitrogen gas flow were developed. A semi-automated prototype was built and tested for its performance of radioactive syntheses of Cisplatin, after which the fully automated module was designed and built. **Results:** Tests to synthesize Pt-195m Cisplatin were successfully performed with the semi-automated prototype, showing a reduction in synthesis time from 2 days to 1 day. Pt-195m Cisplatin was obtained in an overall yield of 48 %, and in high radionuclide and radiochemical purity. The automated module contains a distinguished pharmaceutical part, including a sterile section to produce sterile Pt-195m Cisplatin. All parts in contact with solvents, reagents, and the radioactive reaction mixture or the product, are fully disposable. **Discussion/Conclusion:** A fully automated synthesis module for the GMP production of Pt-195m Cisplatin has been developed. A human pilot study is under preparation. The module will also be used for the development of other Platinum-195m compounds. Since Platinum-195m is a very strong Auger electron emitter, we are currently pursuing development of Pt195m with high specific activity for therapeutic applications as well. 1: Aalbersberg, E.A., de Wit-van der Veen, B.J., Zwaagstra, O., Codée-van der Schilden, K., Vegt, E., Vogel, W.V. OP-442

Automatic synthesis of a PSMA ligand with Al18F

J. Giglio, M. Zeni, E. Savio, H. Engler; CUDIM, Montevideo, URUGUAY.

Introduction: PSMA-targeting positron emission tomography (PET) probes have become available for prostate cancer imaging. The 68Ga-labeled PSMA ligands have been extensively studied. However, 68Ga labeled compounds are produced with generators providing limited activity per synthesis. In contrast, 18F-labelled tracers allow higher doses increasing the number of examined patients. In addition, late images can be acquired in the case of uptake in lymph nodes, to discard inflammation. It is important to transfer the manual synthesis to an automatic module, producing a batch of the radiopharmaceutical with high activity in a safe and effective way. The aim of this work was to optimize the labeling of Al18F-[GLU-UREA-LYS(AHX)-HBED-CC] in a Tracerlab-FXFN (GE) platform. **Materials and Methods:** All reagents were of analytical grade. PSMA was purchased from ABX (PSMA-11). The 18F was produced in a PET-Trace cyclotron

(16,4 MeV) and transferred directly to the Tracerlab-FX$_{FN}$ (GE). The ^{18}F was purified with a QMA cartridge (Waters) and then eluted with 500 µL acetate buffer pH=4.5 (0.5M) from vial 1 to reactor. The first step in the synthesis was the formation of the Al^{18}F. For this purpose, the reactor contained 4,5µL of 0.01M AlCl$_3$ in acetate buffer pH=4.0 (5 min at 25℃). A solution containing 60 µg of PSMA-11, 500 µL of EtOH and 700 µL of 0.5M sodium acetate was then added from vial 4. The reaction took place during 10 minutes at 50℃. The product was purified by HPLC using a C$_{18}$ column (250/10 M&N) with two mobile phases (8mL/min): buffer phosphate 10 mM, pH=6.8: EtOH [A: (98:2) for 15 min. and change to B:(92:8)]. The collected peak was transferred by sterilizing filtration to the final vial. Quality control was performed via radio HPLC and GC. **Results:** The labeling up to the reactor corroborates the formation of the complex Al^{18}F-PSMA. After purification by HPLC, the radiopharmaceutical was achieved with a radiochemical purity higher than 90%. The quality control of the final product fulfilled all the requirements in agreement with USP, such as radiochemical purity (greater than 90%) and residual solvents. Al^{18}F-PSMA was obtained with a yield of 15±2 % (n=3), not decay corrected (NCD) starting off from 500 to 1500 mCi the ^{18}F and with a radiochemical purity of 95 ± 3 %. **Conclusion:** The proposed method allowed the production of Al^{18}F-PSMA with suitable radiochemical purity in a commercial platform. High activities were achieved, with a simple and robust methodology appropriate for clinical purposes.

Accuracy of F-18-FDG-PET/CT in monitoring tumour response after neoadjuvant chemoradiotherapy (nCRT) in patients with locoregional oesophageal cancer

M. J. Valkema[1], B. J. Noordman[1], B. P. L. Wijnhoven[1], V. M. C. W. Spaander[1], J. P. Ruurda[2], G. A. P. Nieuwenhuijzen[3], M. I. Van Berge Henegouwen[4], M. N. Sosef[5], J. J. B. Van Lanschot[1], R. Valkema[1]; [1]Erasmus MC University Medical Centre, Rotterdam, NETHERLANDS, [2]University Medical Centre, Utrecht, NETHERLANDS, [3]Catharina Hospital, Eindhoven, NETHERLANDS, [4]Academic Medical Centre, Amsterdam, NETHERLANDS, [5]Atrium Medical Centre, Heerlen, NETHERLANDS.

Introduction: Neoadjuvant chemoradiotherapy (nCRT) with "CROSS" (NEJM 2012) is effective for downstaging oesophageal tumours. To safely postpone surgery, reliable clinical response evaluations (CREs) should be used to rule out residual locoregional disease without distant metastases. A multicentre feasibility study is underway (preSANO trial, NL41732.078.13) including endoscopy, (deep) biopsies, ultrasound and FDG-PET/CT with planned surgery 12 weeks after nCRT. This preliminary analysis focuses on FDG-PET/CT to predict residual tumour (substantial: >10%=TRG3-4 vs minimal: ≤10% vital cells=TRG1-2,) or metastases after nCRT. **Subjects & Methods:** FDG-PET/CT at baseline and CRE was performed according to EANM guidelines 1.0 (2.3MBq/kg F-18-FDG; scanning 60±5min.). Visual: presence of residual tumour and/or metastases; SUV and SUV/lean body mass (SUL); compared with pathology (resection specimen: golden standard). **Results:** 78 of 205 patients did not proceed to FDG-PET/CT follow-up at 12 weeks after nCRT (CRE2), including 4 with FDG-negative baseline scans and 4 with FDG-positive metastases at 6 weeks (CRE1). In 127 patients at CRE2, FDG-PET/CT was positive in 87. In 5/87, data on histology were still incomplete. 25/87 had no resection (7 postponed, 14 metastases on FDG-PET/CT, 1 died, 3 metastases peroperatively). 33/87 patients had TRG3-4 tumour; SUL-max 4.27±1.63 and SUL-max-ratio tumour/oesophagus (SULR) 2.09±0.77. 12/87 patients had (TRG2) tumour; SUL-max 3.48±0.79 and SULR 1.66±0.33. Of all 27 patients with TRG1, FDG-PET/CT was false positive in 12/27 (44%); SUL-max 3.67±1.14, SULR 1.83±0.57. In all 80 patients with TRG2-3-4-metastases, FDG-PET/CT was true positive in 66/80 (83%). In 40/127 patients at CRE2, FDG-PET/CT was negative. In 7/40 surgery was postponed. 25/40 patients had TRG1-2 tumour; SUL-max 2.28±0.65, SULR 1.22±0.21. Of all 41 patients with TRG3-4, 8/41 were missed on FDG-PET/CT (20% false negative); SUL-max 2.18±0.26, SULR 1.38±0.13. However, in 5/8 surgery was >4weeks after PET/CT. Still, in 7/8 patients radical resection was achieved. Of all patients with postponed surgery, 12 had ≥1 additional FDG-PET/CT during follow-up (25-49.7 weeks). In 6/12, FDG-signal remained low or decreased (ΔSUL-max -0.34±0.48); 6/12 had increased FDG-signal (ΔSUL-max 0.98±0.47). 4/12 had surgery; 3/4 had increased FDG-signal and TRG3-4 tumour at surgery; 1/4 patients had decreased FDG-signal and no tumour (TRG1). All four patients had radical resections. **Conclusion:** These preliminary results indicate that FDG-PET/CT is valuable in follow-up after nCRT. Positive FDG-PET/CT after nCRT predicts residual tumour in 83% of patients. However, visual and quantitative FDG-PET/CT alone is not sufficiently accurate. Therefore, final results of FDG-PET/CT combined with endoscopic ultrasound and (deep) biopsy results should be awaited.

OP-447

^{18}F-FDG-PET/CT For Evaluating Bevacizumab-Based Chemotherapy Combined With Regional Deep Capacitive Hyperthermia In Metastatic Cancer Patients

C. Ferrari[1], G. Ranieri[2], A. Niccoli Asabella[1], A. Di Palo[1], I. Marech[3], M. Porcelli[3], M. Fanelli[1], G. Rubini[1], C. Gadaleta[3]; [1]Nuclear Medicine Unit, AOU Policlinic of Bari, University of Bari, bari, ITALY, [2]Interventional Radiology Unit with Integrated section of Medicaln Oncology, National Cancer Research Centre IRCCS "Giovanni Paolo II", bari, ITALY, [3]Interventional Radiology Unit with Integrated Section of Medical Oncology, National Cancer Research Centre, IRCCS "Giovanni Paolo II", bari, ITALY.

Aim: The new treatment approach based on angiogenesis inhibitors is becoming an attractive target in cancer therapy. Bevacizumab has been investigated in combination with a range of chemotherapeutic agents, but potential synergic anti-angiogenic effects of hyperthermia, based on its ability to induce vasodilatation, improve oxygenation and then reduce hypoxic-inducible factor molecule, are never tested to date in literature. The aim of our study was to analyze the efficacy of bevacizumab-based chemotherapy associated to local deep capacitive hyperthermia (HYP) of patients affected by metastatic colorectal, ovarian and breast cancer, by using ^{18}F-FDG-PET/CT in addition to multidetector Computed Tomography (MDCT). **Methods:** a total of 23 patients with metastatic colorectal (n=16), ovarian (n=5) and breast (n=2) cancer were included in our pilot study. In addition to the standard bevacizumab-based chemotherapy regimen, all patients were treated with HYP. Treatment response assessment was performed by MDCT, taken as reference, and ^{18}F-FDG-PET/CT, at 80 days (timepoint-1) and at 160 days (timepoint-2) after therapy. Chi-squared linear test evaluated if a linear association between response groups (R/NR) and number of previous treatment (none,1,2,3), number of chemotherapy cycles (<6,6,12,>12), number of HYP sessions (<12,12,24,>24), lines of chemotherapy (I,II,III), existed. Survival curves were estimated by the Kaplan-Meier method, with differences assessed by the log-rank test. Significant difference was defined as p<0.05. **Results:** Response to therapy observed at timepoint-1 was: PR in 7/21 (33.3%) patients, SD in 11/21 (52.4%) and PD in 3/21 (14.3%), with a Disease Response Rate (DRR= CR+PR+SD) of 85.7% Eighteen/21 (85.7%) patients completed the clinical-instrumental evaluation at timepont-2: CR was achieved in 6/18 (33.3%) patients, PR in 2/18 (11.1%), SD in 5/18 (27.8%) and PD in 5/18 (27.8%), with a DRR of 72.2%. HYP was well tolerated without additional adverse effects on chemotherapy-related toxicity. A significant linear association between R/NR and lines of chemotherapy (p=0.036), number of chemotherapy cycles (p=0.015), number of HYP sessions (p<0.001), was found. Median OS was 497 days (CI: 414-580±42.3) while median TTP was 339 days (CI: 229-449±56). Both OS and TTP resulted to be influenced by number of chemotherapy cycles (p<0.001) and HYP sessions performed (p<0.001). **Conclusions:** Our pilot study suggests that the combined treatment of bevacizumab-based chemotherapy with HYP has a favorable tumor response, is feasible and well tolerated and can offer a promising option for metastatic cancer patients. Moreover, ^{18}F-FDG-PET/CT confirmed to be a useful and reliable method in evaluating and monitoring the synergic anti-angiogenetic effect of these innovative therapies.

OP-448

SUVmax from 18F-FDG PET/CT may outperform volumetric biomarkers in assessment of primary tumor response to neoadjuvant chemoradiotherapy in patients with esophageal cancer

E. R. Hassan[1], Y. G. Abdelhafez[1], M. A. Abougabal[2], C. Yeh[3], Y. Chao[4], C. Tseng[5], Y. Chang[6]; [1]South Egypt Cancer Institute, Assiut University, Assiut, EGYPT, [2]Faculty of Medicine, Cairo University, Cairo, EGYPT, [3]Chang Gung Memorial Hospital, College of Medicine, Chang Gung University, Department of Pathology, Taoyuan, TAIWAN, [4]Chang Gung Memorial Hospital, College of Medicine, Chang Gung University, Division of Thoracic Surgery, Taoyuan, TAIWAN, [5]Chang Gung Memorial Hospital, College of Medicine, Chang Gung University, Department of Radiation Oncology, Taoyuan, TAIWAN, [6]Chang Gung Memorial Hospital, College of Medicine, Chang Gung University, Chang Gung Memorial Hospital, Nuclear Medicine Department, Taoyuan, TAIWAN.

Aim: To correlate semi-quantitative measure(s) from 18F-FDG PET/CT with the pathologic tumor regression grading (TRG) in patients with locally-advanced esophageal cancer treated with neoadjuvant chemoradiotherapy (NACR) followed by surgery. **Materials & Methods:** A total of 64 patients with T3 or T4 esophageal cancer, candidates for receiving NACR prior to definitive surgical resection, underwent two 18F FDG PET/CT studies: a baseline study performed on average 31 (± 32) days prior to starting treatment; and a post-NACR study performed on average 36 (± 16) days after ending their neoadjuvant therapy. Semi-quantitative parameters measured on the primary tumor site were: SUVmax, SUVpeak, metabolic tumor volume at a threshold of 40% of the maximum pixel (MTV), mean SUV at threshold the same threshold (SUVmean) and total lesion glycolysis (TLG). Post-NACR parameters and percentage change from baseline were compared against TRG. TRG was measured on a 5-point score: 1 = no residual cancer cells, 2 = rare cancer cells, 3 = fibrosis outgrowing cancer cells, 4 = cancer cells outgrowing fibrosis and 5 = absence of regressive changes. **Results:** Area under the curve (AUC) of post-NACR SUVmax, SUVpeak, SUVmean, MTV & TLG were: 81% (95% Confidence Interval [CI]: 69-90%), 79% (67-88%), 81% (69-90%), 68% (55-79%), 71% (59-82%); respectively. AUC for post-NACR SUVmax was higher than that of MTV (Difference in AUC 12.5% & P = 0.04) and TLG (Difference in AUC 10% & P = 0.05). AUC of the percentage change from baseline study for the same parameters were: 74% (62-84%), 67% (54%-78%), 69% (57-80%), 68% (56-79%) & 69% (56-80%); respectively. AUC for the percentage change in SUVmax was higher than SUVpeak (Difference in AUC 8% & P = 0.01). Regression analysis adjusted for age, clinical T & N status identified post-NACR SUVmax as independent predictor of TRG (P < 0.0001, OR = 1.7, [95%CI: 1.3-2.3]). The best predictive cut-

off point of post-NACR SUVmax for identifying residual cancer cells was 3.9; it showed high sensitivity (93%; CI: 77-99%) albeit with low specificity was noticed (54%, CI: 37-71%). **Conclusion:** Among semi-quantitative parameters, SUVmax measured on post-NACR 18F-FDG PET/CT study may represent a better biomarker, compared to volumetric indices, in identifying residual cancer cells in patients with locally advanced esophageal carcinoma treated with neoadjuvant chemoradiation prior to surgery.

OP-449

18F-FDG PET-CT versus MRI-based External Beam Radiotherapy Volumes in Inoperable Uterine Cervical Cancer

J. A. Adam[1], H. Arkies[2], K. Hinnen[1], L. Stalpers[1], J. H. van Waesberghe[3], J. Stoker[1], B. L. F. van Eck-Smit[1]; [1]Academic Medical Center Amsterdam, Amsterdam, NETHERLANDS, [2]Isala Hospital, Zwolle, NETHERLANDS, [3]VU University Medical Center Amsterdam, Amsterdam, NETHERLANDS.

Aim: To assess the impact of 18F-FDG PET/CT (PET/CT) versus MRI on determining the external beam radiotherapy volumes in women with inoperable cervical cancer. **Materials and methods:** To determine treatment volumes for curative chemoradiation, 94 consecutive women with inoperable uterine cervical cancer (FIGO IB-IVA) had an investigation under anaesthesia (IUA), MRI and PET/CT. External beam radiotherapy (EBRT) of the pelvis is extended to para-aortal if suspicious nodes are at common iliac level or higher, and a boost is administered to suspicious nodes. Two radiation oncologists independently reassessed the RT treatment volumes for randomly presented 94 case-descriptions plus MRI-report (blinded to PET/CT), and (in random order) the 94 cases plus PET/CT-reports (blinded to MRI). The elective and boost volumes were registered by region: EBRT pelvis only or with para-aortal extension and an additional boost to suspicious nodes in 8 node regions (para-aortal, common iliac L/R, pelvic vessels L/R, inguinal L/R, presacral). Differences between the MRI or PET/CT-based EBRT volumes and additional boosts were compared by the McNemar test. The number of patients who received EBRT or boost based on the combination of MRI and PET/CT versus MRI alone were compared to assess clinical impact. **Results:** EBRT: Significantly more patients would receive para-aortic extension of the elective EBRT volume based on PET/CT compared to MRI (p = 0.003). Combining PET/CT and MRI, 26/94 patients would receive para-aortic extension of the elective EBRT volume compared to 9/94 based on MRI, leading to a changed EBRT treatment plan in 18% of patients. Boost: In all lymph node regions except right inguinal, more patients would receive additional boost based on PET/CT compared to MRI, which was significant in the para-aortal and both common iliac lymph node regions. Based on a combination of PET/CT and MRI, a change in management of suspicious lymphnodes requiring a boost was seen in 10-15% of the patients, except for inguinal (0-1%) and presacral (5%) regions. **Conclusion**: The elective EBRT treatment plan needs to be changed (i.e. extended) in 18% of patients for EBRT, and regional boost plans need to be changed in up to 15% patients when PET/CT is added to the MRI-based treatment plan. Including suspicious nodes on PET-CT in the treatment plan could result in less ex-field recurrences due to additional para-aortal EBRT and better regional node control due to additional boost to more regions, at a possible cost of more radiation toxicity.

OP-450

Low tracer availability of 68Ga-DOTATOC and 68Ga-DOTATATE in blood for patients with high SSTR density leads to non-linear correlation between SUV and K_i

E. Ilan[1,2], A. Sundin[1,3], I. Velikyan[1,3], M. Sandström[1,2], M. Lubberink[1,2]; [1]Department of Surgical Sience, Uppsala University, SWEDEN, [2]Medical Physics, Uppsala University Hospital, SWEDEN, [3]Medical Imaging Centre, Uppsala University Hospital, SWEDEN.

Introduction 68Ga-DOTATOC and 68Ga-DOTATATE are radiolabelled somatostatin analogues used for diagnosis of somatostatin receptor (SSTR)-expressing neuroendocrine tumours. In addition, their use in treatment follow-up has been proposed. However, it has been shown previously that for these tracers there exists no linear correlation with the net influx rate K_i, assumed to reflect SSTR density. This means that SUV probably does not reflect SSTR density, especially for high K_i values. The plateau in SUV for higher K_i values could be due to low availability of 68Ga-DOTATOC/68Ga-DOTATATE in the blood because of large amounts of SSTR in these patients, and hence tumor-to-blood ratio may be a better alternative than SUV. The aim of this study was to evaluate the correlation between tumor-to-blood ratio (TBR) and K_i. **Materials and methods** Ten patients with metastatic neuroendocrine tumors underwent a 45-min dynamic scan immediately after injection followed by a whole-body (WB) PET/CT scan at 1 h post injection of 68Ga-DOTATOC and 68Ga-DOTATATE on consecutive days. 50% isocontour VOIs were drawn over tumours in the whole body scan and in the last frame of the dynamic scan and transferred to all other frames, resulting in tumour time-activity curves. Net influx rate K_i was determined by nonlinear regression of an irreversible two-tissue compartment model using a descending aorta input curve. Amounts of tracer in blood was determined by drawing 70% isocontour VOIs in the descending aorta. The relation between TBR and K_i was evaluated using linear regression and compared to the relation between K_i and SUV. **Results** A linear relationship between TBR and K_i was found, with a Pearson correlation coefficient (R^2) of 0.98 and 0.99 for 68Ga-DOTATOC and 68Ga-DOTATATE respectively. For patients with high SSTR density, corresponding to high K_i values, blood radioactivity concentrations at 1 h p.i. were significantly lower ($p<0.05$) than for patients with low SSTR density both for 68Ga-DOTATOC and 68Ga-DOTATATE. **Conclusion** A linear relation with high correlation was found between TBR and Ki both for 68Ga-DOTATOC and 68Ga DOTATATE. It is likely that the non-linear relation between SUV and K_i is due to low availability of tracer in blood in patients with high SSTR density. TBR reflects SSTR density more than SUV, and is as such the preferred measure for semi-quantitative assessment of 68Ga-DOTATOC and 68Ga DOTATATE uptake.

OP-451

Evaluation of Surgically Excised Non-functioning Pancreatic Endocrine Tumors Followed Radiopeptide Treatment; To Optimize PRRT, Aiming to a Longer Term Survival

G. S. Limouris[1], G. Fragulidis[2], M. Paphiti[1], D. Voros[2], V. R. McCready[3]; [1]Medical Faculty, National and Kapodistrian University of Athens, Athens, GREECE, [2]II Surgical Dept of 'Aretaieion' Hospital, Medical Faculty, National and Kapodistrian University of Athens, Athens, GREECE, [3]Institute Cancer Research, Sutton Surrey & Royal Sussex County Hospital, Brighton, UNITED KINGDOM.

Introduction: We first report on adjuvant peptide receptor radionuclide therapy (PRRT) in 18 non-functional pancreatic neuroendocrine tumours (NF-PNETs) followed surgical lesion excision as an adopted technique in our Institution, aiming to optimize PRRT for a longer term survival. **Subjects and Methods:** Eighteen NF-PNETs received adjuvant PRRT i.a., after transhepatic infusions; 6 of them received ^{111}In-Octreotide, in a dosage of 4.0 -7.0 GBq, (12 cycles with treatment intervals of 5-8 weeks) and 12 n.c.a. ^{177}Lu-DOTATATE in a dosage of 7.4 GBq (6 cycles with treatment intervals also of 5-8 weeks), following their surgical excision as first-line treatment. Twelve patients underwent pancreato-duodenectomy and 6 distal pancreatectomy and splenectomy. Intraoperative Liver Ultrasonography was performed to enhance missed lesion detection. Liver metastases were present in 7 patients[3 bilobar, 4 unilobar]. The latter underwent hemihepatectomy or segmentectomy; in bilobar patients, concomitant major hepatectomy was planned and were subjected to pre-operative evaluation of the future liver remnant by Indocyanine Green clearance test. Prophylactic cholo-- cystectomy was planned to obviate adverse events due to the use of somatostatin analogues. Response assessment was classified according to RECIST criteria. Absorbed doses delivered to metastases, kidneys and red marrow were calculated according to OLINDA 1.0 program. CT/MRI were performed before and after the end of treatment and monthly US images for follow up. **Results:** In all 18 cases immediately resulted in a significant down slowing of the tumour aggressiveness clinically and biochemically confirmed, accelerating the therapeutic efficacy, prolonging the survival rate assessed by Kaplan-Mayer curves (50,4 mo for surgically excised pts versus 33 mo in non surgically treated pts) . **Conclusion:** In pts with metastatic liver-lesions, scheduled for surgical exeresis complementary, adjuvant radiopeptide therapy slows down the tumour aggressiveness, accelerates the therapeutic efficacy and improves the patients RECIST score assessment in favour to the partial remission scoring. The drawback of the concept is that surgical lesion debulking lurks the danger of tumour dissemination. The latter drives us to the skepsis that P R R T should precede the scheduled surgical excision by a therapeutic scheme of 2-3 cycles of n.c.a. Lu-177 DOTATATE for tumour ablation.

OP-452

^{177}Lu-PSMA Therapy Response Prediction in Metastatic Prostate Cancer Patients by Textural Heterogeneity Parameters in Baseline ^{68}Ga-PSMA PET Scans

Z. Khurshid[1], H. Ahmadzadehfar[1], F. C. Gaertner[1], L. Papp[2], N. Zsóter[3], H. Strunk[1], M. Essler[1], R. A. Bundschuh[1]; [1]Universitätsklinikum Bonn, Bonn, GERMANY, [2]Universitätsklinikum Wien, Wien, AUSTRIA, [3]Mediso Medical Imaging Systems, Budapest, HUNGARY.

Introduction: Radioactive labled PSMA analogs are of increasing importance for diagnosis and therapy of prostate cancer. In the era of personalized therapy emphasis is being placed on earlier response prediction and risk stratification of patients before the start of therapy. Analysis of textural heterogeneity parameters has been associated with determination of innately aggressive and therapy resistant cell lines thus emphasizing their importance in therapy planning. The objective of the current study was to assess the predictive ability of tumor textural heterogeneity parameters from baseline ^{68}Ga-PSMA PET prior to ^{177}Lu-PSMA therapy. **Materials and Methods:** Retrospective analysis of 70 patients with metastatic prostate cancer was performed. All patients were planned to undergo ^{177}Lu-PSMA therapy and underwent a pre-therapy ^{68}Ga-PSMA PET/CT scan. Interview Fusion (MEDISO Medical Imaging) was used for entire analysis of the PET/CT data. 3D volumes (VOIs) of 3 lesions each in bones and lymph nodes were manually delineated in static PET images (also in prostate and liver when applicable). Five PET based textural heterogeneity parameters (COV, entropy, homogeneity, contrast, size variation) were determined. Results obtained were then compared with clinical parameters including pre and post therapy PSA, alkaline phosphate, bone specific alkaline phosphate levels and ECOG criteria. Spearman correlation was used to determine statistical dependence among variables. ROC analysis was performed to estimate the optimal cutoff value and AUC. **Results:** Entropy showed a negative correlation (r_s = -0.327, p = 0.006, AUC = 0.695) and homogeneity showed a positive correlation (r_s = 0.315, p = 0.008, AUC = 0.683) with change in pre and post therapy PSA levels. Other parameters did not show statistically significant correlations. **Conclusions:** Our study showed a potential for response prediction of ^{177}Lu-PSMA therapy through one baseline ^{68}Ga-PSMA scan only. It also suggested that the more heterogeneous the tumor was in PSMA expression the more responsive it was to PSMA therapy, thus contributing efficiently towards treatment planning and improvement in overall diagnostic accuracy. This can also help in risk stratification and advanced strategy making for personalized therapy. However prospective studies need to be performed in the future to evaluate the clinical benefit.

OP-453

Dose Escalation Experience with 177Lu-PSMA-617

H. Rathke[1], F. L. Giesel[1], P. Flechsig[1], K. Kopka[2], W. Mier[1], M. Hohenfellner[3], U. Haberkorn[4], C. Kratochwil[1]; [1]University Hospital Heidelberg, Heidelberg, GERMANY, [2]Division of Radiopharmaceutical Chemistry, , German Cancer Research Center (dkfz), Heidelberg, GERMANY, [3]University Hospital Heidelberg, Department of Urology, Heidelberg, GERMANY, [4]University Hospital Heidelberg; Clinical Cooperation Unit Nuclear Medicine, German Cancer Research Center (dkfz), Heidelberg, GERMANY.

Introduction: Current treatment protocols for ^{177}Lu-PSMA-617 therapies were cautiously derived from dosimetry data, but their practical appropriateness have not yet been proven clinically. We retrospectively report our clinical observations using four different treatment activities. **Methods:** Forty patients with advanced prostate cancer and positive uptake in PSMA-imaging were treated in fractions of 4 GBq / 80 nmol, 6 GBq / 120 nmol, 7.4 GBq / 150 nmol or 9.3 GBq / 150 nmol ^{177}Lu-activity / precursor-amount (n=10, respectively) every 2 months. Blood cell count was checked every 2 weeks, PSA-response every 4 weeks; other effects were assessed per anamnesis. **Results:** PSA response presented no correlation to treatment activity. However, 2/10, 5/10, 5/10 and 8/10 patients with doses of 4, 6, 7.4 and 9.3 GBq completed all 3 cycles indicating a positive dose-response-relationship. Hematological toxicity was also irrespective of treatment activity as one grade-3 thrombocytopenia was observed in the 4 GBq and one grade-3 leukopenia in the 7.4 GBq-group, both patients had diffuse red-marrow infiltration and chemotherapeutical pretreatment. In the 9.3 GBq-group only one patient had grade-4 thrombocytopenia but in contrast to the other groups the mean platelet count for all patients chronically decreased over time. **Conclusions:** If patients with diffuse red marrow infiltration and extensive chemotherapeutical pretreatments are excluded, treatment activities up to three injections of 9.3 GBq ^{177}Lu-PSMA-617 every two months are well tolerable. We recommend no further dose escalation as the MTD seems to be reached.

Do.MoRe: Clinical Dosimetry for 90Y Radioembolization

OP-454

The impact of the hemoglobin level in liver radioembolization is confirmed by TOF-PET/CT based dose-response in hepatocellular carcinoma

M. Hesse, P. D'Abadie, S. Walrand, F. Jamar, R. Lhommel; Cliniques Universitaires Saint-Luc, Brussels, BELGIUM.

Background: Radionuclide therapy rarely takes into account anemia, but, as shown recently, the hemoglobin (Hb) level impacts the dose-response of non-primary hepatic metastases. Patients with hepatocellular carcinoma (HCC) treated by ^{90}Y radioembolization were retrospectively analyzed for a similar impact of the Hb level on the tumor response with respect to the mean dose (D) and to the equivalent uniform dose (EUD). **Methods:** Absorbed doses of 9 liver tumors sites in six patients post ^{90}Y radioembolization were computed by a 3D convolution of the TOF-PET based ^{90}Y distribution with a dose deposition kernel. D and EUD were evaluated from the tumors dose volume histograms and further linearly corrected for the Hb level measured on the day of the radioembolization procedure. Tumor responses at 2 and 4 months post-therapy were assessed from follow-up acetate or FDG TOF-PET scans. **Results**: Correcting for the Hb level significantly improves the linear correlation

of the dose-response both using D and EUD. The value of the parameter k modeling the Hb level impact was found in good agreement with the one previously obtained for 18 non-primary hepatic metastases sites. Furthermore a good linear correlation was also found when analyzing the dose response of the HCC tumors and of the non-primary hepatic metastases together. **Conclusions:** This study confirms a significant impact of the Hb level on the HCC tumor response similarly to the one previously observed for non-primary hepatic metastases. From our results the dose-response of HCC tumors appears similar to the one of non-primary hepatic metastases. This supports the study of methods for correcting tumor hypoxia and the introduction of liver radioembolization earlier in the treatment course, preferably before the induction of anemia by the chemotherapies or by the disease itself.

OP-455

Effect of differences in CT- and SPECT-based tumor delineation on tumor dose and dose response following 90Y Selective Internal Radiation Therapy (SIRT)

*A. Balagopal, A. Mahvash, **S. C. Kappadath**; UT MD Anderson Cancer Center, Houston, TX, UNITED STATES OF AMERICA.*

Purpose: There is no general consensus on methodology for tumor contouring for 90Y-SIRT dosimetry. The objective of this study is to investigate the effect of differences between CT- and SPECT-based tumor delineation on estimation of tumor dose and dose-response relationship. **Materials and Methods:** Quantitative 90Y-SPECT/CT for 34 HCC patients that underwent 90Y-SIRT were analyzed. 53 tumors (D>2.5cm) were segmented by an interventional radiologist on CT of SPECT/CT that was registered to the contrast-enhanced diagnostic CT or MRI of the liver. CT tumor contours were expanded (CT+5mm) and contracted (CT-5mm) by 5 mm (SPECT voxel) on all sides to represent inter-observer contouring. 4 SPECT based segmentations were performed: variable SPECT threshold to match the CT tumor volume (SPECTvol); fixed 20% and 30% SPECT threshold (SPECT20% and SPECT30%); variable SPECT threshold to match the CT contour while excluding necrotic core (SPECTnecro). 3D voxel dose maps were generated (Monte Carlo DOSXYZnrc/EGSnrc), and the mean dose was extracted for all tumor definitions. Dice Similarity Coefficient (DSC, to estimate the spatial overlap) and correlation analysis were performed between different contouring methods and the original CT (CToriginal) contours. Logistic regression was used to estimate the mean absorbed dose for 50% probability of EASL response (D50p). The Positive Predictive Values (PPV) and Negative Predictive Values (NPV) were also computed. **Results:** Absorbed doses for all tumor contour definitions were strongly correlated (r>0.94; p<0.001) with those from CToriginal. Relative to CToriginal contours, average errors observed on mean tumor doses were ±14% for CT±5mm, and 6.5%, -4.8%, 6.1%, and 4% for SPECTvol, SPECT20%, SPECT30%, and SPECTnecro contours. The median DSC value was highest for SPECTnecro (=79%) and lowest for SPECT20% (=52%) contours. D50p for CToriginal contours was 91Gy that changed to 86Gy and 115Gy for CT+5mm and CT-5mm, and to 107.3Gy, 94.8Gy,

104.5Gy, and 95.76Gy for SPECTvol, SPECT20%, SPECT30%, and SPECTnecro contours. Change in D50p relative to CToriginal was <10% only for CT+5mm, SPECT20%, and SPECTnecro contours. D50p as threshold dose provided PPV=68%, NPV=64% for CToriginal, that changed to PPV=70%, NPV=57% for SPECT20%; and PPV=61%, NPV=55% for SPECTnecro. **Conclusion:** The inter-observer variability in CT-based tumor contours translated to errors of ~15% in estimates of mean tumor dose and D50p. Although average errors in mean tumor dose and D50p with SPECT-based contours were <20%, their spatial coherence was poor. In addition, there were substantial differences in PPV and NPV for SPECT-based contours with highest values realized for CToriginal contours.

OP-456

Absorbed dose correlates with metabolic response to radioembolization of liver metastases with resin 90Y-microspheres

M. Cremonesi, M. E. Ferrari, F. Botta, F. Guerriero, C. Garibaldi, C. De Cicco, M. Colandrea, C. M. Grana, G. Varano, G. Bonomo, D. Paolo, F. Orsi, R. Orecchia; Istituto Europeo di Oncologia, Milano, ITALY.

Aim: The aim of the present study was to investigate possible correlation between absorbed dose and tumour response by means of a Tumour Control Probability (TCP) in liver metastases treated with radioembolization (RE) with resin 90Y-microspheres. To assess tumour response, the analysis of parameters from FDG-PET/CT has been preferred to RECIST criteria based on CT, as often, metabolic response has been proven to anticipate morphologic response. **Methods**: Patients with chemo-refractory liver metastases from solid tumours scheduled to receive RE underwent FDG-PET/CT scan before and 6 weeks after RE. 99mTc-MAA (75-111 MBq) were injected two weeks before RE to simulate treatment and perform previsional dosimetry based on SPECT fused to contrast CT. Response assessment was performed according to PERCIST criteria. The variations (%) of PET parameters versus basal examination were evaluated to establish Complete Response (CR), Partial Response (PR), Stable Disease (SD), and Progressive Disease (PD). **Results**: 22 patients and 29 lesions were suitable for analysis. Patients had hepatic lesions from colon-rectal (11), breast (7), ovary (1), endometrial (1), parotid (1) cancer, cholangiocarcinoma (1). All patients received a single treatment of RE, with a median activity of 1.7 GBq (range 0.6-2.9) of 90Y-microspheres. Median (range) tumour absorbed doses was 100 (30-443) Gy; average dose (standard deviation) was: 129 (100). Metabolic response rate of lesions as assessed with PERCIST was: CR=31%; PR=28%; SD=24%; PD=17%. Two different TCP curves were obtained by probit regression when considering: i) PR or CR as endpoint1; ii) CR only as endpoint2 (p<0.01 in both cases). For tumour doses > 170 Gy, only CR were observed. TCP of 20%, 50%, 75%, and 90% were obtained at: i) 51, 80, 104, and 125 Gy; ii) 81, 121, 153, and 183 Gy, respectively. **Conclusion**: Despite the variety of primary tumours, the relatively low cohort of patients, and the implicit uncertainty of the previsional dosimetry with 99mTc-MAA, our preliminary data provided evidence of correlation between response based on PET/CT parameters and absorbed dose. These encouraging results need to be confirmed with more ample dataset and possibly differentiation depending on tumour type. Other PET/CT parameters for response such as the metabolic tumour volume, and tumour lesion glycolisis are being considered for comparison with PERCIST and possible improved correlations.

OP-457

Is there any relationship between ^{90}Y-PET absorbed doses and damage to the target non tumoral liver (TNTL) after SIRT?

L. Sancho Rodriguez[1], M. Rodríguez.Fraile[1], J. Bilbao[1], M. Iñarrairaegui[1], C. Beorlegui Arteta[2], A. Benito[1], V. Moran[1], J. Martí-Climent[1], E. Guillen[1], B. Sangro[1]; [1]Clínica Universidad de Navarra, Pamplona, SPAIN, [2]Universidad de Navarra, Pamplona, SPAIN.

Aim: To identify whether a relationship exists between ^{90}Y-PET absorbed doses and damage to the TNTL after SIRT. **Material and Methods:** Retrospective analysis of patients with primary and secondary liver tumors submitted to SIRT with ^{90}Y-resin microsphere between 2012 and 2015. All patients received right lobar treatment, had pre-treatment and follow-up (8-10 weeks after SIRT) cross-sectional imaging (CT/MRI) and laboratory determinations. MIM processing software (Sureplan, MIM Software Inc, Cleveland, OH) was used for image processing and dosimetry calculation. Firstly, the volumes of interest were drawn using contrast-enhanced CT/MR to aid in anatomical delineation. Contours were automatically transferred using rigid registration and manual adjustment to fused ^{90}Y-PET/CT images. Afterwards, 3D voxel dosimetry was performed by means of the local deposition method. Absorbed dose parameters studied (D_{mean}, D_{20}, D_{50}, D_{70} y D_{90}) were obtained from the TNTL dose-volume histograms (DVHs). Finally, volumes of interest were drawn using contrast-enhanced CT/MR follow-up images to measure TNTL volume changes after SIRT. Spearman's P was performed to determine the correlation between TNTL absorbed doses and changes in TNTL volumes. Regression model was used to determine which ^{90}Y-PET absorbed dose predicts better the volume change. Changes in the TNTL volumes and laboratory determinations between baseline and 8-10 weeks post-treatment were studied using Wilcoxon test. **Results:** Fourteen patients were evaluated. The majority of them had hepatocellular carcinoma (78.6%) and suffered from cirrhosis (71.4%). The median predicted absorbed dose to the TNTL for ^{90}Y-PET was 23.3 Gy. A weak association was observed between ^{90}Y PET absorbed doses and volume changes, except for D_{20}, which is the absorbed dose that best correlates with TNTL atrophy (P=0.546, moderate association, p < 0.05). D_{90} is the next best (R=0.513, moderate association, p > 0.05). If atrophy is attempted to be predicted from ^{90}Y-PET absorbed doses, a positive relation is observed in all cases with weak determination coefficients, except for the scatter-plots between D_{20} and atrophy and for that between D_{90} and atrophy. The presence of cirrhosis does not modify the effect of the absorbed dose on atrophy. Analytical data do not significantly change between baseline data and 8-10 weeks after SIRT. **Conclusion:** The higher the absorbed dose to the TNTL,

the greater the atrophy produced. D_{20} is the parameter that best correlates with the atrophy produced in the TNTL although it has not been possible to predict the degree of atrophy from ^{90}Y-PET absorbed doses.

OP-458

Evaluation of 99TcMAA SPECT and 90Y PET similarity metrics on clinical cases with reference values from multiple realizations of phantom scans

J. Mikell, B. Majdalany, R. Srinivasa, K. Younge, Y. Dewaraja; University of Michigan Hospital and Health Systems, Ann Arbor, MI, UNITED STATES OF AMERICA.

Introduction: To implement treatment planning based on 3D dosimetry from 99TcMAA SPECT scans, it is necessary to establish that the SPECT spatial distribution is predictive of the 90Y distribution. The purpose of this work is to use clinical scanning protocols with phantom data to report baseline similarity metrics that quantify agreement between 99TcMAA SPECT and 90Y PET, and then evaluate patient scans relative to phantom metrics. **Methods:** A liver phantom with multiple lesions was filled with 99Tc and scanned five consecutive times with SPECT/CT; the procedure was repeated for 90Y PET/CT with identical uptake ratios. To account for differences in spatial resolution, Gaussian blurring was applied to PET. Rigid registration between the MAA-CT and PET-CT was performed to transform and resample the SPECT to the PET. To account for misregistration, up to +/- 3 voxel shifts were applied. 99TcMAA SPECT and Y90 PET images for radioembolization patients (n=17) were processed in an analogous manner. For both phantom and patient data, voxel-level Pearson's correlation coefficient (r) and mean squared difference (MSD) between images normalized to the maximum were evaluated. Multiple instances of metrics were generated for different blurring and registration perturbations. Additionally, threshold contours from 5 to 50% of the maximum were generated on SPECT and PET for a segmentation based similarity metric (dice). **Results:** For the 5 phantom scans, r (MSD) ranged from 0.94-0.95 (7.3e-5,9.2e-5) without misregistration and blurring. Blurring marginally improved r and worsened MSD, and misregistration widened the range to 0.69-0.95 (7.2e-05, 2.6e-04). Phantom dice values for all thresholds were > 0.7. For patients, with blurring and registration perturbations, the average r (MSD) was 0.59 +/- 0.19 (7.8e-4 +/- 8.8e-4) and ranged from 0.16 to 0.94 (3.6e-5 to 3.5e-3). Taking the maximum r from all registrations for each patient showed 2, 8, 9, and 11/17 patients had r > 0.8, 0.7, 0.6, and 0.5 respectively. The average dice was 0.64 +/- 0.22 for the 5% thresholds ranging from 0.18 to 0.89, while the 50% threshold average dice was 0.16 +/- 0.19 ranging from 0 to 0.56. Angiography-defined catheter positioning differences between the two procedures correlated (0.63) with MSD, but not with r. **Conclusion:** We quantified the contribution of imaging related effects (resolution, misregistration and noise) when evaluating similarity metrics between 99TcMAA-SPECT and Y90 PET images. In some patients similarity metrics were not in the range predicted from the phantom study due to additional clinical variability not modeled.

OP-459

Retrospective Dosimetry for Hepatocellular Carcinoma Radioembolization with Yttrium-90 Resin Microspheres Planned using Body Surface Area Method

M. Kafrouni[1,2], M. Fourcade[1], S. Vauclin[2], A. Ilonca[1], D. Mariano-Goulart[1]; [1]Montpellier University Hospital - Department of Nuclear Medicine, Montpellier, FRANCE, [2]Dosisoft SA, Cachan, FRANCE.

Aim: The body surface area (BSA) method has been the reference activity planning method in radioembolization for yttrium-90 (^{90}Y) resin microspheres for the last years. Today, interest is growing for personalized dosimetry with advanced tools similar to the ones used in external beam radiation therapy. This study aims to retrospectively analyze tumor dosimetry for hepatocellular carcinoma (HCC) patients treated with an activity of ^{90}Y-resin microspheres planned by the BSA method. **Materials and Methods:** Thirty-eight HCC patients (representing 44 different treatments) treated by radioembolization with ^{90}Y-resin microspheres (SIR-Spheres®, SIRTeX, North Sydney, Australia) were included in this study. Injected activity was planned using the BSA method. Personalized dosimetry was retrospectively performed using a dedicated software (PLANET® Dose, DOSIsoft, Cachan, France). Dose was computed using a convolution method based on voxel-S factors. This was done for both predictive and *in vivo* dosimetry respectively based on ^{99}Tc^m-MAA-SPECT and ^{90}Y-microspheres-PET images. 3D dose distribution was analyzed to the tumor delineated on the injected CT/MR beforehand. Objective response (OR) (either complete or partial response) was assessed three and six months after treatment using RECIST, mRECIST and EASL criteria. **Results:** Administered activities calculated using the BSA method ranged from 0.29 to 2.59 GBq with a median of 1.17 GBq (for target volumes from 12 to 1787 cm^3). The mean (±SD) and median predicted doses to the tumor over the 44 treatments were 70 Gy (± 47) and 55 Gy respectively. The mean (±SD) and median absorbed doses to the tumor evaluated on ^{90}Y-PET images were 63 Gy (± 41) and 54 Gy respectively. This retrospective evaluation shows a large variability of dose values and they are in most cases lower than the recommended 120 Gy threshold for treatment efficacy. This might be explained by the fact that the BSA method is not based on functional imaging which takes into account tumor uptake. Response rates were lower than 25% for any criteria used. The receiver-operating characteristic analysis was conducted in each case. Compared to the literature, the first results indicate low dose threshold values with a low significance due to the limited number of patients included and in particular of OR. **Conclusion:** These results highlight that 3D personalized dosimetry could provide more controlled and reproducible dose planning compared to the BSA approach. Dose-volume histogram analysis is ongoing and is expected to provide more robust indices to characterize the predictive value of dose distribution heterogeneity within the tumor volume.

OP-460

Assessment of dose-response correlation of selective internal radiation therapy (SIRT) for liver metastases from colorectal cancer (mCRC)

H. Levillain[1], G. Marin[1], T. Guiot[1], Z. Wimana[1], M. Vouche[2], P. Delatte[2], E. Woff[1], A. Hendlisz[3], B. Vanderlinden[1], P. Flamen[1]; [1]Nuclear Medicine Department, Jules Bordet Institute, Université Libre de Bruxelles (ULB), Brussels, BELGIUM, [2]Radiology Department, Jules Bordet Institute, Université Libre de Bruxelles (ULB), Brussels, BELGIUM, [3]Digestive Oncology Department, Jules Bordet Institute, Université Libre de Bruxelles (ULB), Brussels, BELGIUM.

Introduction: SIRT is an established and effective treatment modality for mCRC. Post-SIRT ^{90}Y-microspheres-PET/CT (^{90}Y-MS-PET/CT) enables the measurement for a patient-specific treatment dosimetry. Were this dosimetry correlated to treatment outcome, it could be a valuable tool for early treatment adaptation in case of under treatment of the lesions. This study aims at defining the dose-response correlation of SIRT for mCRC patients. **Materials and Methods:** This retrospective study was based on 17 mCRC patients treated with SIRT, who underwent pre/post-SIRT-FDG-PET/CT and post-SIRT ^{90}Y-MS-PET/CT. FDG-PET/CT image quality was assessed using predefined criteria and ^{90}Y-MS-PET/CT images were acquired and reconstructed according to the Quantitative Uptake Evaluation in SIR-spheres Therapy (QUEST) recommendations (Willowson et al., 2015). ^{90}Y-MS injected activity was computed using partition model based on ^{99m}Tc-macro-aggregates-albumin-SPECT/CT. Response assessment was performed on pre/post-SIRT-FDG-PET/CT images for lesions with a diameter >2 cm (AWserver 3.2 software, GE-Healthcare®). Lesions were delineated using a threshold corresponding to twice the normal liver mean SUV at baseline measured in a 3 cm diameter sphere. The lesion-based metabolic response was assessed by Total Lesion Glycolysis (TLG) decrease computed with SUV normalized to lean body mass. Lesions delineated on the FDG-PET/CT were projected on the anatomically registered ^{90}Y-MS-PET/CT. Voxel-based 3D dosimetry was performed on the ^{90}Y-MS-PET/CT and lesions' mean absorbed dose (D_{mean}) was measured (Planet Onco 3.0, Dosisoft®). Median[1st Quartile; 3rd Quartile] were computed for both TLG-decrease and D_{mean}. The correlation coefficient R^2 between D_{mean} and TLG-decrease was calculated using an EC50 dose-response model (GraphPad 7.01, Prism®). Finally, TLG-decrease was dichotomized into responders (≥50%) and non-responders (<50%) (Flamen et al., 2008). The D_{mean} (mean±SD) was computed for each category and a paired t-test was performed. **Results:** This study included 47 evaluable mCRC lesions. The median D_{mean} was 57[39; 82] Gy. For the TLG-decrease, the median was 97[32; 100]%. The correlation coefficient between TLG-change and D_{mean} was R^2=0.86. The D_{mean} for responders (N=32) and non-responders (N=15) was 82±46 and 36±16 Gy respectively (P<0.001). **Conclusion:** To our knowledge, this is the first study to demonstrate a correlation between the lesions' metabolic response and mean absorbed dose based on ^{90}Y-MS-PET/CT for mCRC patients treated with SIRT. This high correlation, obtained with a clinically applicable method, enables a rapid and precise prediction of the SIRT efficacy, allowing early treatment adaptation in case of under treatment of the lesions.

OP-461

On the origin of spurious extrahepatic activities observed in ^{90}Y nonTOF-PET imaging post radioembolization

S. Walrand, M. Hesse, F. Jamar, R. Lhommel; Université Catholique de Louvain, Brussels, BELGIUM.

Aim: Unlike TOF-PET, nonTOF-PET often shows spurious extra-hepatic activity in post liver ^{90}Y radioembolization imaging. We recently discovered using MC simulations how two physical effects largely unknown by the medical physicist community produce this discrepancy between nonTOF and TOF PET imaging. We think valuable for the nuclear physicians to be aware of the mechanism of these spurious extrahepatic activities generation. **Methods**: Acquisition of a ^{32}P vial was performed on a GSO PET system. This is the ideal setup to study the impact of bremsstrahlung x rays on the true coincidence rate regarding that no positron emission and no crystal radioactivity are present. Monte Carlo simulation of the acquisition was performed using Gate-Geant4. Additionally, an acquisition of a ^{111}In source was acquired on the GSO PET in order to assess its energy resolution. **Results:** Long exponentially decreasing tail in the system energy resolution was observed in the ^{111}In acquisition. This results from the poor scintillation light collection when using pixelized crystal as a consequence of the numerous photons reflections between the photoelectric location and the photo-detector. In line with recent studies (Strydhorst et al. Med Phys 2016) no explanation of the discrepancy was found using the standard Gate-Geant4 simulation tool. However, implementation in Geant4 of the internal bremsstrahlung (IB) and of the exponential tail succeeded in explaining the discrepancy between nonTOF and TOF PET imaging. IB emission during beta decay results from the beta particle interaction with the decayed nucleus. For most beta emitters, including ^{90}Y and ^{32}P, above 500 keV IB largely supersedes the external bremsstrahlung of the beta particle in water (Cengiz & Almaz, Rad Phys Chem 2004). **Conclusion:** A fraction of the high energy x rays, mainly produced by the IB, are backscattered when hitting a crystal pixel via the Compton effect and reach an opposite crystal pixel with an energy around 200 keV. Due to the long energy resolution tail, a fraction of these backscattered x rays are detected as true coincidences together with the energy deposited in the first crystal pixel hit. These faked true coincidences generate spurious extrahepatic activity in the reconstructed image. As these detections in two opposite crystal pixels are separated by a time delay being the TOF for the backscattered x ray to cross the whole field of view, they are automatically located outside the useful field of view, and thus outside the patient, by TOF based reconstruction algorithms.

Feasibility of an Iodine-123 FP-CIT striatal quantitative measurement method with a partial volume effect correction

T. Kanenawa[1], S. Ota[1], A. Takaki[2], S. Ito[3]; [1]Graduate School of Health Sciences, Kumamoto University, Kumamoto, JAPAN, [2]Teikyo University, Omuta, JAPAN, [3]Facuty of Life Sciences, Kumamoto University, Kumamoto, JAPAN.

Purpose: Iodine-123 FP-CIT has been used to evaluate the distribution density of dopamine transporters in Lewy body disease (LBD), including Parkinson's disease and dementia with Lewy bodies. A new ^{123}I-FP-CIT striatal quantification method with a partial volume effect (PVE) correction was experimentally demonstrated by using a phantom study. The specific binding ratio of this method (new-SBR) has was obtained by calculating activities (MBq/ml) of both striatal and non-specific region with PVE and scatter corrections on the single photon emission tomography (SPECT) images. This method overcame the weakness in which the SBR depends on the system performance. However, the feasibility of this method in clinical studies has not been clarified. The purpose of this study was to confirm the feasibility of use of the new striatal quantification method. **Materials and Methods**: After fusion of SPECT/CT and MR images, the left- and right-side regions of interest of striatal and non-specific regions were obtained by tracing the striatal outline of the MR images. The activities of the striatal and non-specific regions were calculated by multiplying each SPECT count by the two different count-activity conversion coefficients and PVE correction factors. The PVE correction factors were experimentally determined by a striatal phantom filled with I-123 solution. Our study included 22 patients with clinically suspected LBD who had undergone ^{123}I-FP-CIT SPECT for 3 h after the tracer injection. The diagnosis was LBD in 10 patients and non-LBD in 12 patients. The new-SBR based on the activity of ^{123}I-FP-CIT SPECT was calculated, and correlation with the clinical features was analyzed. **Results**: The new-SBR values of the LBD (1.23-5.36, mean 2.12) were significantly lower than those of the non-LBD (2.78-6.88, mean 3.92, p < 0.01). The conventional SBR values of the LBD (1.28-4.45, mean 1.64) were lower than those of the non-LBD (1.53-4.13, mean 2.77, p < 0.2). The area under the curve (AUC) of the new-SBR by the receiver operating characteristic analysis was 0.821, and the AUC of the conventional SBR was 0.688. The AUC of the new-SBR was 15% higher than that of the conventional SBR. **Conclusion**: The LBD and non-LBD can be clearly distinguished by using the new SBR method with the PVE correction. This finding indicates the possibility of clinical routine study.

OP-472

Image classification of synaptic dopamine transporters ^{123}I-Ioflupane by machine learning techniques

J. Camacho-Cañamón[1], M. Guiote Moreno[2], A. Santos Bueno[2], E. Rodríguez Cáceres[2], E. Carmona Asenjo[2], J. Vallejo Casas[2], P. A.

Gutiérrez[1], C. Hervás-Martínez[1]; [1]University of Córdoba, CORDOBA, SPAIN, [2]H.U. Reina Sofia. UGC Medicina Nuclear Cordoba, CORDOBA, SPAIN.

Purpose : Apply machine learning techniques to classify functional brain imaging used in the differential diagnosis of movement disorders. **Material and methods:** In this study, SPECT images obtained after iv administration of 5 mCi of ^{123}I-ioflupane in 75 patients were analysed, in order to detect alterations in the distribution of activity (presynaptic dopamine transporter). The definitive diagnosis identified 51 % of patients with Parkinson's disease (PD) patterns, while the remaining 49 % corresponded to non-ill patients. Images were preprocessed using the PE-TRA software to orient and perform spatial normalisation, and a three-dimensional 79x95x69 matrix (i.e. 517,845 voxels) was obtained for each patient. In order to classify these images, a regularised logistic regression model using all voxels as input data was trained. The regularisation parameter was adjusted by an error estimator based on cross-validation. The model was evaluated by measuring the area under the ROC curve from a 5-fold experimental design. **Results:** The number of voxels was reduced to 259 by selecting the 0.05 % of coefficients of the logistic regression model with the highest absolute value. With these 259 voxels, the model obtained an AUC of 0.9905 with a sensitivity of 94.44 % and a false positive rate of 5.26 %. The characteristics chosen by the model were consistent with those used by skilled diagnosticians (caudate and putamen areas). However, the model highlighted other voxels outside these regions that were relevant for the task of diagnosis. **Conclusions:** The use of machine learning techniques has proved to be plausible for classification SPECT imaging of patients with PD, obtaining results similar to those of medical experts. The model obtained has shown areas of interest to the diagnostic study of PD beyond the caudate and putamen.

OP-473

Optimization Of Acquisition Time For18F-FLUTEMETAMOL PET/CT In Patients With Early-Onset Dementia

M. Isolani, A. Pieri, G. Serreli, C. Ghetti, M. Scarlattei, C. Lazzara, L. Ruffini; Azienda Ospedaliera- Universitaria Ospedale Maggiori di Parma, Parma, ITALY.

Background: Accumulation of β-amyloid in the brain plays a role in the degeneration of neurons in Alzheimer's disease and it's one of several patological characteristics implicated in Alzheimer's disease development. ^{18}F-Flutemetamol PET/CT is a diagnostic tool used to assess β-amyloid neuritic plaque density in patients with early-onset dementia, including Alzheimer's disease and other causes of cognitive decline. Patients must stay perfectly still the entire scan time and it's especially challenging to patients with dementia. Aim of the present study was to investigate the effect of decreasing acquisition time in order to improve patient compliance on ^{18}F-Flutemetamol accuracy. **Methods:** This pilot study included 10 patients evaluated for cognitive disorders. All patients were submitted to PET/CT scan (DiscoveryIQ GE Healthcare©) 90 minutes after intravenous injection of 185 MBq ^{18}F-Flutemetamol.

DiscoveryIQ PET/CT is a whole-body hybrid system operating in 3D detection mode and it provides up to 22cps/kBq. PET and CT data were co-registrated. PET acquisition was performed in LIST MODE for 20 minutes and PET images were reconstructed at different time intervals (20 minutes and 10 minutes) by VUE point and Q.Clear technologies (GE Healthcare©). Subsequently, data were processed by CortexID Suite software (GE Healthcare©). This software analyses radiotracer uptake in different brain's areas. Automated Z-scores were generated from CortexID and compared with a database of normal subjects. Z-score results of standard images and half- processed images (10 minutes) were compared by Pair T-Test (corrected by Bonferroni adjustment). **Results:** Z-score values did not show any statistically significant difference between standard images (20 minutes) and processed half-time images (10 minutes) for the evaluation of β-amyloid plaque density (P=0.01). These results mean that Z-score values were the same in brain maps at 10 and 20 minutes. **Conclusion:** The findings of this study showed that 10 minutes ^{18}F-Flutemetamol PET/CT acquisition provides accurate information regarding radiotracer uptake. Z-score values generated from CortexID Suite software suggested that acquisition time can be reduced from 20 to 10 minutes without a loss of clinical information. Reduction of acquisition time was possible using a PET/CT scan with a high sensivity detector. Using decreased time acquisition improves patients' comfort and reduces motion artifacts as well. **Keywords:** ^{18}F-Flutemetamol PET/CT ; β-amyloid plaque, processed images, acquisition time, patient comfort.

OP-474

Clinical, long term efficacy of PRRT in NEN patients with advanced, nonresectable, progressive hindgut and cancer of unknown primary (CUP)

A. D. Kolasinska-Cwikla[1], A. Lewczuk[2], L. Bodei[3], M. Kidd[4], J. R. Buscombe[5], I. M. Modlin[6], **J. B. Ćwikła**[7]*; [1]MSC Memorial Cancer Centre and Institute Maria Sklodowska-Curie, Warszawa, POLAND, [2]Medical University of Gdansk,, Gdansk, POLAND, [3]Memorial Sloan Kettering Cancer Center, New York, NY, UNITED STATES OF AMERICA, [4]Wren Laboratories, Branford, CT, UNITED STATES OF AMERICA, [5]Addenbrooke's Hospital, Cambridge, UNITED KINGDOM, [6]Yale, New Haven, CT, UNITED STATES OF AMERICA, [7]Faculty of Medical Sciences, University of Warmia and Mazury, Olsztyn, POLAND.*

Purpose: To evaluate the clinical long term effectiveness of Peptide Receptor Radionuclide Therapy - PRRT (^{90}Y or [177]Lu [DOTA0, D-Phe1, Tyr3]-octreotate), based on overall survival (OS) and progression free survival (PFS), in patients with extensive, progressive, non-resectable neuroendocrine neoplasm (NEN) hindgut or CUP (cancer of unknown primary) origin. **Materials and Methods:** Overall 22 patients with histologically proven hindgut (n=8) and CUP (n=14) NEN, were treated with PRRT (^{177}Lu-PRRT n=8; ^{90}Y-PRRT n=14). Clinical responses were assessed 6 weeks after completing therapy and then after at the 3-month intervals. The clinical efficacy was determine evaluating performance status (PS) of patients (ECOG/Karnofsky score), reduction of clinical symptoms of hormonal hyperproduction in case of secretor tumours also level of CgA. Any adverse events

(AEs) determine using CTC-NCI-AEs v. 4.01). The median OS and PFS were assessed using Kaplan Meier methods. Radiological response was classified according to RECIST 1.0.**Results**: Median OS for all subjects was 42,5 months (CI 28.7-52.5); PFS 18 months (CI 14.2-26.8). There was no significant difference in median OS between hindgut and CUP OS 48.5 (CI 25.2-71.5) vs. 28.5 (20.9-51.4) months, (P>0.05 Cox-Mantel test), but the trend favored those with hindgut NEN. Similarly, no significant difference in median PFS was noted between these groups (22.0 vs. 17.0 months). There was no difference in OS between female vs. male patients 46.0 (CI 23.8-62.0) vs. 30.0 (20.5-56.4) months and PFS 22.0 (CI 12.4 27.1) vs. 17.0 (9.6 32.9) months (P>0.05). Also, there was no significant difference in OS and PFS between those patients who were treated ^{177}Lu vs. [90]Y PRRT 45.0 vs. 28.5 months (OS), and 20.0 vs. 15.5 months (PFS), which could be related to the small number of patients in both groups [177]Lu (n=8) and [90]Y (n=14). Previous therapy with SST analogues vs. no analogues did not influence OS (42.5 vs 37 months) and PFS (17.0 vs 20.0 months). There was however a significant change in clinical stage as PS (ECOG/Karnofsky) before and 6 weeks after PRRT in all subjects.**Conclusions**: PRRT is equally effective in terms of OS and PFS in subjects with advanced non-resectable, progressive NEN, either hindgut or CUP. A more pronounced clinical effect with improved OS and PFS is seen more frequently in patients with hindgut NEN treated ^{177}Lu DOTATATE over CUP and/or [90]Y.

OP-475

A review of thyroid blockade strategies used in paediatric I[123] MIBG scintigraphy, and an evaluation of their relative effectiveness

B. Thurlow[1], T. Melhuish[2], P. Leanne[1], E. Morris[1], S. Johns[2], M. Guy[2], S. King[3], L. Biassoni[1]; [1]Great Ormond Street Hospital for Children NHS Foundation Trust, London, UNITED KINGDOM, [2]University Hospitals Southampton NHS Foundation Trust, Southampton, UNITED KINGDOM, [3]University of the West of England, Bristol, UNITED KINGDOM.

Aim: A dual centre study, to determine which medication and dosage frequency provides optimal thyroidal protection in paediatric I-123 metaiodobenzylguanidine (mIBG) scans. Purpose of the study was: 1. To compare the protective effect of potassium perchlorate versus potassium iodate; 2. To evaluate the protective effect of a single dose of potassium iodate administered 30 minutes prior to I-123-mIBG injection compared to administrations over 48 hours and over 72 hours. **Method:s** A total of 212 patients underwent I-123-mIBG scintigraphy during a 6 year period. This cohort was retrospectively categorised into two groups. In group 1, 50 patients received potassium perchlorate (KClO4) and 50 patients received potassium iodate (KIO3) according to the EANM and SPC guidelines. In group 2, 162 patients received differing dosages and frequency of potassium iodate; • Sub-group-(A) 49 patients received a single stat loading dose of KIO3 30 minutes prior to I-123-mIBG injection; • Sub-group-(B) 61 patients received a loading dose of KIO3 1 hour prior to I-123-mIBG injection with 2 further maintenance doses over 48 hours; • Sub-group-(C) 52 patients received KIO3

24 hours prior to I-123-mIBG injection, with a 2 further maintenance doses within 72 hours. Thyroid uptake was scored visually using a Likert scale (1-5) by a nuclear medicine physician blinded to the interventions received. Quantitative analysis of thyroid uptake was performed using ROIs drawn around the thyroid and a background area to calculate the counts-per-pixel and thyroid-to-background ratio. **Results:** The Mann-Whitney-U test found a statistically significant difference in the Likert responses for KClO4 and KIO3 (U=806, Z=-3.518, p=0.002). No statistical difference was noted when comparing KIO3 given over 48 and 72 hours (U=1120, p=0.455, Z=-0.748). The quantitative data indicated that 72% of patients fell within the normal distribution for thyroid activity when using KClO4 prior to I-123-mIBG injection compared to 97% when using KIO3. In subgroup-(A) Likert grading yielded 40 patients with no uptake, 7 patients with minimal and 2 patients with visible uptake. The average thyroid ROI to background ROI mean counts ratio was 1.042±0.095, showing comparable blockade effectiveness for single dose KIO3. **Discussion:** The results indicate that potassium iodate provides a greater level of protection from unbound radioiodine compared to potassium perchlorate. Furthermore, the visual and quantitative data indicate that potassium iodate given 30 minutes prior to I-123-mIBG injection provides comparable blockade effectiveness to the lengthier administrations, meaning a single stat dose is both safe and practical.

OP-476

Evaluation of the influence of adipose tissue in attenuation and scattering correction in Myocardial Perfusion SPECT/CT

B. Guerreiro[1], S. Valente[2,1], P. Pereira[1], R. Rosa[1], L. Vieira[3,4], E. Sousa[3], F. Branco[2,1], T. Freixo[2], P. Almeida[4,2], F. D. Jonge[2], T. C. Ferreira[2]; [1]Escola Superior de Tecnologia da Saúde de Lisboa, Instituto Politécnico de Lisboa, Lisboa, PORTUGAL, [2]Hospital dos Lusíadas, Departamento de Medicina Nuclear, Lisboa, PORTUGAL, [3]GIReS-Escola Superior de Tecnologia da Saúde de Lisboa, Instituto Politécnico de Lisboa, Lisboa, PORTUGAL, [4]Instituto de Biofísica e Engenharia Biomédica, Faculdade de Ciências, Universidade de Lisboa, Lisboa, PORTUGAL.

Aim: To evaluate the influence of thoracic Adipose Tissue (AT) on myocardial counts in cardiac SPECT/CT, after Attenuation Correction (AC) and Compton Scatter Correction (SC). **Materials and Methods:** We have used a tissue-equivalent anthropomorphic thorax phantom (RSD, Alderson Phantom) and a GE gamma-camera Infinia Hawkeye 4 equipped with 4 slice helical CT. Three different parts of the heart phantom, located on its superior (41.7 mL), medial (13.5 mL) and inferior (8.9 mL) regions were filled with ^{99m}Tc concentrations of approximately 0.03 MBq/mL, 0.10 MBq/mL, and, 0.16 MBq/mL, respectively. The phantom was filled with distilled water excepting for lungs and liver. The phantom was imaged and AT was simulated acquiring the phantom with different thicknesses of soft tissue (35 mm) and fat (10 mm and 30 mm). SPECT was acquired using a step and shot acquisition mode over 180º and 30 projections (64x64 pixels, zoom=1.33) for each one of the two detectors. The time from each projection varied from 25 to 44 seconds,

to correct for ^{99m}Tc decay. CT was acquired in axial mode with a slice thickness of 5 mm and 256x256 pixel matrix. The data were reconstructed using FBP, OSEM Resolution Recovery (RR), OSEM RR AC and OSEM RR AC SC methods. Semi-Quantitative analysis was made using FBP as standard. **Results:** The results show that when compared to FBP, OSEM RR, OSEM RR AC and OSEM RR AC SC a significantly higher number of counts is recovered, which is expectable. Increasing the amounts of adipose tissue leads to an increased amount of counts in all regions studied, suggesting that CT based AC may be biased. This effect is particularly visible for thicker fat layers. When the SC is added the percentage of counts are slightly decreased compared to OSEM RR AC. **Conclusion:** Quantitative data obtained for cardiac SPECT/CT using AC based CT may be biased when imaging obese patients and people using these methods should test them at their own departments before applying them to patients.

OP-477

Planar versus SPECT Acquisition in Pulmonary Embolism: comparison of some European Practices

T. C. S. Melo[1], D. Vieira[1], A. Nunes[2], C. Sibley-Allen[2], D. Dasgupta[2], H. Ahmed[2], S. M. Piekut[3], S. Mirzaei[3], C. Sonneck-Koenne[3], W. Zehetner[3], J. A. Silva[4], M. Oliveira[4], J. Nery[4], R. Castro[4], L. F. Metello[1,5]; [1]ESS-IPP, ATC & Curso Med. Nuclear, Porto, PORTUGAL, [2]Department of Nuclear Medicine Guy's and St.Thomas Hospital, London, UNITED KINGDOM, [3]Wilhelminenspital, Department of Nuclear Medicine and PET center, Vienna, AUSTRIA, [4]CHP-Hosp. Sto.António EPE, Dept. de Med.Nuclear, Porto, PORTUGAL, [5]IsoPor-Azores,Dept. de Med. Nuclear e Imagiologia Molecular, Angra do Heroismo, I.Terceira-Azores, PORTUGAL.

In recent years, the role of V/Q scintigraphy in the diagnosis of Pulmonary Embolism (PE) has diminished. Although the introduction of V/Q SPECT brought improvements in the diagnostic accuracy. The purpose of this study is to understand if SPECT brings any added value to the diagnosis of PE. In order to observe the differences between some departments in Europe, this study includes cases from 3 different Nuclear Medicine department in Europe. **Material and Methods:** 35 patients (F=18; M= 17; 60±15 years old) with clinical suspicion of PE were included in this study. All patients performed both planar and SPECT images, either for ventilation and perfusion phases. Data was acquired in three distinct European Nuclear Medicine Departments: Portugal (n=10), Austria (n=13) and the United Kingdom (n=12), using three different gamma cameras. In two of the NM Departments, ^{99m}Tc-Technegas was used for the ventilation phase, performed before the perfusion study. In the other site, [81m]Kr was used for the ventilation phase. ^{99m}Tc-MAA was used in all the patients in the perfusion phase. SPECT images were processed through Hybrid Recon-Lung v1.1.2 option in Hermes workstations using OSEM (2 iterations and 8 subsets), Butterworth 3D filter, 0.5 cycles/cm cut-off frequency and power 8.All patient data were anonymized and analyzed by seven experienced NM physicians, who were not aware about data origin or imaging protocols. Data analysis consisted in the evaluation of matched/mismatched defects in V/Q scans and if these data

was consistent between planar and SPECT acquisitions. SPSS v24.0 was used for statistical analysis and a Cohen's K test was performed to evaluate the agreement between planar and SPECT data and between physicians. Paired Wilcoxon signed-rank tests were used to compare the number of matched and mismatched defects between both techniques. **Results:** Considering 245 diagnostics (35 patients x 7 physicians, based on planar images, 29 cases (12%) were reported as positive for PE, 209 negative (85%) and 7 as indeterminate (3%). Based on SPECT, 42 cases (17%) were reported as positive for PE, 199 negative (81%) and 4 as indeterminate (2%). Considering physicians individually, 6 of them changed the report from negative to positive for PE at least in one case, but this number varied from 1 to 5. **Conclusions:** Our results suggest that SPECT, given the improved spatial resolution and thus the ability to detect smaller lesions, increases the number of cases reported as positive for PE, while slightly reducing the number of indeterminate cases.

OP-478

Preliminary results for: Optimised diagnostics of lung embolus with ventilation/perfusion SPECT/CT with use of CPAP prior to lung scintigraphy

J. P. Paludan, S. R. Andresen, J. Abrahamsen, M. S. Jensen, C. Høyer; Region Hospital Viborg, Viborg, DENMARK.

Background: When a patient is undergoing a lung scintigraphy in order to verify the presence of pulmonary embolism, the patient inhale a radioactive tracer (aerosol). If the patient suffers from chronic obstructive pulmonary disease (COPD), the gas tends to accumulate in radioactive hot spots in areas with mucus accumulations, along with reduced dispersion of the tracer in distal airways. The result is reduced quality of the scintigraphic image, and thus likely reduced diagnostic accuracy of the method. The aim of the project is to establish if it is possible to gain a higher diagnostic accuracy if Continuous Positive Airway Pressure (C-PAP) treatment is administered before inhalation of the radioactive tracer. **Method and Materials:** All patients with tracer hotspots in their initial ventilation/perfusion scintigraphy and which are deemed suitable will be invited to participate in the study. After inclusion, all patients will be randomized between an intervention group and a control group. Both groups will be asked to return between 1 and 3 days after their first ventilation/perfusion scintigraphy. The intervention group will have CPAP treatment just prior to the ventilation/perfusion scintigraphy. The control group will only have a ventilation/perfusion scintigraphy performed. After completion of both studies, all ventilation images will be evaluated. Both an objective and subjective evaluation will be performed. Objective evaluation: Regions of interest will be drawn around all tracer hotspots and also around the entire lung. A hotspot to total lung counts index will then be calculated and compared. Subjective evaluation: An experienced physician will determined which ventilation image had more tracer hotspot in comparison with the other and report the number of hotspots. **Results:** Our preliminary trial has showed a decrease in both the hotspot to total count ratio (0.20 to 0.06) and number of hotspots (5 to 3). Both results could indicate better distribution of the tracer, lead-

ing to a greater degree of certainty in the physicians report. But more trials are necessary in order to eliminate day to day variations in the ventilation image. **Conclusion:** Post CPAP treatment imaging, have shown that patients with tracer accumulation have fewer accumulation of tracer hotspots after CPAP treatment and a better hotspot to total count ratio.

OP-479

Designing a PET uptake room: ALARA does not like all concrete walls

M. Hesse, S. Walrand, F. Jamar; Cliniques Universitaires Saint-Luc, Brussels, BELGIUM.

Introduction: Today radioprotection actors demand tremendous efforts from nuclear medicine facilities to achieve always smaller absorbed dose reduction. In spite of the increasing complexity in achieving such absorbed dose reduction, basic and approximate tools based on build up factors and tabulated occupancy factors are still commonly used by radioprotection actors in most countries. These tools often overestimate the shielding requirement in PET facilities. This study reports an actual case where Monte Carlo (MC) simulations showed that an additional concrete wall, demanded by the radioprotection actors, increases the global absorbed dose to the medical staff in PET routine. **Material and Methods:** The new PET facility uptake room was intended to welcome up to 2 patients in bed. Obeying to the radioprotection actor's demand, the room was split into 2 boxes by a solid concrete wall. Absorbed dose rate to the medical staff was evaluated by MC simulations using actual occupancy factors in 4 setups: one or two patients in the room with or without the additional wall. Patients and nurse were modelled with anthropomorphic phantoms, and realistic ^{18}FDG biodistribution extracted from ICRP report 106 were used in the MC simulations. **Results:** The simulated patient self-absorbed dose was in good agreement with the OLINDA/EXM value. Averaged with the actual occupancy factors, the presence of the additional wall increases the dose rate to the nurse. Indeed in the most frequent case of only one patient in bed (80% of the time), the reduction of the working space, induced by the additional wall, decreases the distance between the nurse and the walls. As a consequence the nurse is more exposed to the gamma rays backscattered by the concrete walls. **Conclusions:** This realistic MC modeling of a real case supports that state of the art tools such as MC should be mandatory in uptake room designs. Originally developed to estimate the shielding in between the worker and the source, build-up factor based tools are not appropriate to design a shielding that surrounds the worker and the patient together. Live adaptation of the shielding to the number of patients using mobile panels might be preferable to concrete walls in PET facilities from an ALARA point of view.

OP-480

Comparison of the methods for eye lens dose measurement by a Monte Carlo method

M. Fulop[1], J. Hudzietzová[2], P. Ragan[1], J. Sabol[3], D. Solivajs[4], P. Vlk[5]; [1]Slovak Medical University, Bratislava, SLOVAKIA, [2]Faculty of Biomedical Engineering, CTU Prague, Kladno, CZECH REPUBLIC, [3]Faculty of Safety Management of PACR, Prague, CZECH REPUBLIC, [4]Slovak Legal Metrology, NGO, Bratislava, SLOVAKIA, [5]BIONT Inc., Bratislava, SLOVAKIA.

Introduction: Three systems for monitoring of eye lens exposures (SMELEs) of staff handled radiopharmaceuticals were evaluated. **Material and Methods:** The SMELEs are based on TL detectors MCP-7 and/or MCP-Ns with 3 mm built-up plate that are located in five positions on a head. The first system (SMELE-1) uses the TLD located at base of the nose root. The SMELE-2 uses two TLDs in positions above the eyebrow. The SMELE-3 is the system EYE-DTM developed in framework of ORAMED project for intervention radiology. The Monte Carlo code MCNPX and Zubal voxel head phantom with the SMELEs pinned on protective eyewear were used for calculation of angle dependence of the SMELEs responses and exposures of eye lenses irradiated by ^{137}Cs, ^{131}I, ^{99m}Tc, ^{90}Y, ^{18}F and ^{11}C point sources from angles 0°, 45°, 90° and 180° at distance of 50cm. The comparisons of the SMELEs responses and the values of eye lens exposures were performed in the same amount of averaged absorbed dose ($D_{average}$). The use of voxel head phantom allows to simulate details of the human head form face and internal structure of its tissues and cavities. The human eyes created by means of mathematical formulas contains simple constructed lenses and they were inserted into the Zubal voxel phantom to achieve a higher accuracy in the determination of the $D_{average}$ in the eye lenses. **Results:** MCNPX simulations were verified for the MCP-7 located on the polyethylene calibration cylinder phantom of diameter 20cm irradiated by ^{137}Cs source from distance of 90cm. All three SMELEs have been calibrated by the cylindrical water phantom (recommended by ORAMED project) point source ^{137}Cs at distance of 100cm in front and side of irradiation geometries. The value $D_{average}$ measured by the systems for monitoring radiation exposure of lenses were in all considered irradiation geometries higher than $D_{average}$ monitored by dosimeters located on the chest. According to results of the simulations of angle dependence of the SMELEs responses, better agreements of the $D_{average}$ values of eye lenses exposures were with the responses of SMELE-1 and SMELE-2. **Conclusions:** Monitoring of $D_{average}$ on the chest is not sufficient for the assessment of the exposure of the eye lens in the departments of nuclear medicine. SMELE-2 is recommended as a monitor of eye lens irradiation because this system is able to distinguish which eye received higher dose. Gratitude: This post arose for the project/SGS17/OHK4/1T/17.

OP-481

The Influence of Age and Gender on Bone Marrow Fat-Fraction

M. Salas-Ramirez[1], J. Tran-Gia[1], A. M. Weng[2], H. Köstler[2], M. Lassmann[1]; [1]Department of Nuclear Medicine, University of

Würzburg, Würzburg, GERMANY, [2]Department of Diagnostic and Interventional Radiology, University of Würzburg, Würzburg, GERMANY.

Aim: In adults, the active marrow is located mainly in the axial skeleton, and the active bone marrow is continuously converted into inactive bone marrow. A recently introduced magnetic resonance imaging (MRI) sequence CAIPIRINHA DIXON - Volume interpolated breathhold examination (CD-VIBE) enables a voxel-wise quantification of the fat-water fraction. The aim of this study was to investigate the effect of age and gender in the marrow conversion based on this MR technique to test if the values proposed by ICRP for a reference man are valid assumption for absorbed dose calculations in molecular radiotherapies. **Materials and Methods:** In a retrospective study, fat-water data acquired with the CD-VIBE sequence in a consecutive series of patients referred to MRI for various medical reasons were analyzed. Prior to the study, the accuracy of this technique for fat-water separation was verified in a phantom study by comparison with the MR spectroscopy (gold standard for MR-based fat-water imaging). All patients were scanned in a clinical 3T scanner (MAGNETOM Prisma, Siemens Healthcare). Only images that involved all lumbar vertebrae were included. Average values of fat-fraction were obtained by drawing VOIs in all lumbar vertebrae (L1-L5). Additionally, the fat-fraction in the os coxae and the proximal femur (head and neck) were evaluated in 11 patients. **Results:** A total of 44 patients were included in the study (21 females between 19-87 years, 23 males between 23-85 years). A linear regression analysis of the lumbar vertebrae data showed a slightly higher slope for females (0.005±0.001 fat-fraction/year) than for males (0.003±0.001 fat-fraction/year), indicating that the marrow conversion is slower in males than in females. While the absolute fat-fraction value is higher in males than in females in the life span between 20-40 years, this tendency is inverted in the interval between 40-50 years. The median/maximum/minimum fat-fraction values were 40%/70%/12% (lumbar vertebrae), 86%/92%/62% (proximal femur), and 52%/78%/40% (os coxae). In contrast, ICRP Publication 70/89 proposes 30% for lumbar vertebra, 75% for proximal femur, and 52% for os coxea in the reference man, which disagrees with our patient collective. **Conclusion:** This study demonstrates an age- and gender-dependency of marrow conversion in a collective of 44 patients. These results suggest that the constant fat-fraction values as published by the ICRP for radiation protection purposes should be replaced by a patient-specific approach to optimize the assessment of absorbed dose to the bone marrow in molecular radiotherapies.

OP-482

Doses in female carer due to a paediatric nuclear medicine patient using ICRP biokinetic data and Monte Carlo simulations

V. de Sousa[1], G. Cardoso[1], A. I. Santos[1,2]; [1]Serviço de Medicina Nuclear – Hospital Garcia de Orta, Almada, PORTUGAL, [2]Nova Medical School – Universidade Nova de Lisboa, Lisboa, PORTUGAL.

Purpose/Introduction: Nuclear medicine (NM), using low-dose radiation procedures, is increasingly contributing for the diagnostic and treatment of paediatric patients. One of the characteristics of NM is that the patients become radioactive, which results in a certain exposure to people around them. In the case of paediatric patients, they are usually accompanied by their mother, who frequently carries the children next to the chest, increasing the proximity with radiosensible organs. This scenario is of particular concern if the mother is pregnant. Dose assessment in these cases is important to ensure that it is kept acceptably low. **Subject & Methods:** Monte Carlo simulations were performed using MCNPX 2.7.0 computer program developed by the Los Alamos National Laboratory, a paediatric voxel phantom (Baby), an adult female voxel phantom (Irene) and a 24 weeks' pregnant voxel phantom (Katja). These phantoms were developed at the Helmholtz Zentrum München - German Research Center for Environmental Health. A Tc-99m source was simulated separately in the kidneys, bladder contents and total body of Baby phantom. Tally F6 (deposited energy per mass in a cell per emitted particle) was used to obtain the absorbed dose in the breast and thyroid of Irene and in Katja foetus. It was assumed that Baby started at the most extreme point in the y-axis of the female phantoms setup. Multiplying these values by the cumulated activity, the absorbed doses were estimated. The cumulated activity in the kidneys and other organs of interest, $Ã_S$, were calculated using the available ^{99m}Tc-MAG3 biokinetic data from ICRP 80. **Results:** The estimated absorbed dose in Irene's breast and thyroid was 5.49x10^{-9} and 2.20x10^{-9} mGy, respectively, and the absorbed dose in Katja foetus was 2.79x10^{-8} mGy. Using the tissue weighting factors from ICRP 103 the effective dose was also estimated as being 6.59x10^{-10} mSv for breast, 8.79x10^{-11} mSv for thyroid and 2.79x10^{-8} mSv for the foetus (since w_R=1 and $w_{totalbody}$=1). **Discussion/Conclusion:** The annual average effective dose from natural background radiation is approximately 2.4 mSv worldwide. Thus, it can be observed that the results of effective dose for breast and thyroid due to the exposure of a paediatric nuclear medicine patient are very low. When comparing these values with the results of dose in foetus, it is noticed that the effective dose is higher, although still very small, suggesting that there is no need for concern.

OP-483

Comparison between fetal dose estimates for [^{18}F]FDG PET imaging in pregnant patient using static and dynamic bladder voiding models

*C. M. Dartora[1], N. G. Cavedini[1], **A. M. Marques da Silva**[1,2]; [1]PUCRS, Porto Alegre, BRAZIL, [2]Brain Institute, Porto Alegre, BRAZIL.*

Aim: The aim of this study was to assess the effect of bladder voiding model in the pregnant patient on fetal radiation dose estimates for [^{18}F]FDG PET imaging, using Monte Carlo simulation with GATE (Geant4 Application for Tomography Emission). **Materials and Methods:** GATE version 7.1 was used to simulate a [^{18}F]FDG uptake in a 24 weeks pregnant woman voxelized phantom , named Katja [1], an altered version of the ICRP adult female reference model. All organ masses but adipose tissue,

skin, urinary bladder and uterus remained the ICRP reference masses. Two bladder emptying models were used: a dynamic model with bladder voiding after 1 hour (19.6% A_0), 2 hours (4.15% A_0) and 4 hours (0.33% A_0); and a static full bladder or no voiding model. The distribution of [^{18}F]FDG for the woman was based on Mejia et al. (1991) [2]. The uptake of fetus and placenta was 0.22% and 0.81% of the total activity distributed in the woman, respectively. The ^{18}F modeling considered both particles (positrons) and back-to-back gamma emissions. The physical processes library used in the GATE simulation was Standard and Penelope for Rayleigh scattering. Fetal absorbed doses for both bladder-emptying models were calculated and compared. **Results:** The contribution of the dynamic bladder and static bladder to the total fetal dose was 14% and 17%, respectively. The relative difference of fetal doses considering different bladder voiding models was 32% (1.56 10^{-3} mGy/MBq for dynamic voiding, and 2.06 10^{-3} mGy/MBq for no voiding). **Conclusion:** A comparison was performed between the fetal dose produced by a [^{18}F]FDG distribution in a pregnant woman voxelized phantom with two bladder emptying models using Monte Carlo GATE. The contribution of more than 10% to the total fetal dose due to maternal bladder content shows the importance of pregnant woman voiding in [^{18}F]FDG PET imaging. Bladder models for pregnant woman in literature are diverse and usually not based on real data from pregnant women. PET imaging of pregnant woman recommendations indicate the use of oral and venous hydration, diuretic drugs and bladder catheters to reduce fetus exposition. The considerable difference between the absorbed fetal doses for the voiding models points out to the importance of hydration procedures to improve the bladder emptying regimen. **References:** [1] BECKER, J et al. OP-484

Optimisation of administered activity for ^{18}F-FDG examination on children

J. Oddstig[1], A. Stenvall[1], H. Almquist[2], L. Jönsson[1], B. Olsson[2], C. Hindorf[1]; [1]Department of Radiation Physics, Lund, SWEDEN, [2]Department of Clinical Physiology and Nuclear Medicine, Lund, SWEDEN.

Aim: The recommendations for administered activity stated in the EANM guidelines for ^{18}F-FDG examinations of children results in an effective dose of 6.7 and 7.5 mSv for 1 and 15 years old patients, respectively. This exceeds the effective dose given to adults with up to 40 %. Since children are more sensitive to radiation the aim of this study was to investigate if the effective dose can be reduced with preserved image quality for children undergoing ^{18}F-FDG examinations. **Methods:** 46 children, aged 2-19 years and with a weight range 11-116 kg, underwent ^{18}F-FDG examination on a GE Discovery 690 PET/CT. The patients were administrated with 3 MBq/kg or more and examined 60 minutes after administration with at least 4min/bed. Acquisition in list-mode allowed studies for patients to be truncated to correspond to studies of an injected activity of 3 MBq/kg and an acquisition time of 3 and 4 min/bed, respectively. Regions-of-interest were

drawn in the liver. The SNR (signal-to-noise ratio) was calculated as the ratio of the activity concentration and the standard deviation. The SNR for the paediatric groups were compared with the SNR from 20 adult normal weighted patients (administered activity 4 MBq/kg, examined 60 minutes after administration, 2 min/bed) on the same camera and with same reconstruction parameters. **Results:** Using an administered activity of 3 MBq/kg resulted in SNR=10.9 for children < 40kg and a scan time of 4 min/bed, and in SNR=10.6 for children > 40 kg and a scan time of 3 min/bed. The normal weighted adult patients had a mean SNR of 10.9. This results in an effective dose of 2.9 mSv for a 1 year old and 4.1 mSv for a 15 years old. The corresponding effective dose using EANM guidelines would be 6.7 mSv and 7.5 mSv. The new administration schedule gives a factor of 2.3-1.8 lower effective doses than the EANM guidelines recommendation. **Conclusions:** Our result shows that it is possible to significantly reduce the administered activity and effective dose for ^{18}F-FDG examinations of children with a preserved signal-to-noise ratio.

OP-485

Validation of Siemens CARE kV for use with PET/CT: dose reduction and PET quantification

T. Jørgensen[1], M. A. Micheelsen[2], E. Dupont[3], N. A. Bebbington[4]; [1]Department of Clinical Physiology and Nuclear Medicine, Zealand University Hospital, Næstved, DENMARK, [2]Department of Clinical Physiology and Nuclear Medicine, Zealand University Hospital, Køge, DENMARK, [3]Department of Biomedical Engineering, Zealand University Hospital, Køge, DENMARK, [4]Siemens Healthineers, Aarhus, DENMARK.

Introduction: CT image quality and dose are influenced by tube voltage, mAs and patient size. On the basis of the topogram, Siemens CARE kV automatically selects the kV and reference mAs combination which gives the greatest dose saving to the patient, according to a user-defined image quality reference. However, changing tube voltage from the 120kV standard can alter CT HUs. Caution is therefore exercised in PET/CT before clinically implementing kV optimisation features, as this could affect attenuation maps and PET quantification. The aim was to assess dose savings and impact on PET quantification using CARE kV in a series of phantom conditions. **Subjects and Methods:** This investigation used four phantom conditions of varying size and density, each containing F-18 sources: 'Lungman' with no additional fat; 'Lungman' with fat layer; NEMA IEC image quality phantom with water background; Jaszczak phantom with water background. Using a CT image quality reference of 120kV/50mAs, 1 PET and 5 CT scans of each phantom were undertaken, with CARE kV on (scanner chooses optimal kV), and with tube voltages forced at 140, 120, 100 and 80kV. Dose savings were evaluated by comparing DLP to the 120kV reference scan. PET quantification was assessed by comparing F-18 activity concentrations to the 120kV reference CTAC PET reconstruction. **Results:** Dose savings up to 23% were observed with CARE kV applied (maximum dose saving with Jaszczak phantom at 100kV). None of the four phantom conditions gave low enough attenuation for the scanner to choose 80kV as the optimal

tube voltage. Forcing inappropriate kVs, lower or higher than those chosen by the scanner's CARE kV application, increased dose by up to 63% (maximum dose increase in Lungman with fat at 80kV). Despite some differences in mu-map voxel values with different kV, differences in AC PET activity concentration were considered negligible (≤0.7%) when CARE kV was applied (maximum difference found in max activity concentration in Lungman at 100kV). Although greater differences (≤2.9%) were seen across the forced kV range (maximum difference for mean activity concentration at 80kV in Lungman plus fat), differences in activity concentration were still not considered clinically significant, with most <1%. For the forced kV range it was observed that differences in PET quantification were greatest with sources in air (≤2.9%), compared with sources immersed in water (≤1.7%). **Conclusion:** Considerable dose savings can be made by applying CARE kV, and resulting kV changes have a negligible impact on PET quantification.

OP-486

Measuring, Monitoring, and Reporting Effective Dose on an Hybrid Equipment: one year results and challenges to integrate with MDCT

G. Tosi[1], A. Chiti[2], K. Marzo[1], F. Zanca[3]; [1]Humanitas Research Hospital, ROZZANO, ITALY, [2]Humanitas University, ROZZANO, ITALY, [3]GE Healthcare, BUC, FRANCE.

Purpose: The aim of this study was to measure, monitor and report effective dose in nuclear medicine and to assess current challenges in integrating these measures with CT. **Methods and Materials:** In 2014 we connected a CT-PET to a dose tracking software and started to collect dose data from CT modality; in late 2015 the software was upgraded to a version which includes a NM module for dose tracking. Data from the PET part of the scanner, in terms of administered activity and effective dose, were also collected. **Results:** Data from 11000 CT doses and 2700 PET doses were collected, mostly from: Whole Body (WB) ^{18}F-FDG (63.2%), WB ^{11}C-Choline (12.8%), WB ^{68}Ga-DOTA-TOC (5.5%), Head ^{11}C-Methionine, for a total of 18.4 % of the whole activity of the scanner. CT mean DLP (mGy*cm) data values were (range between brackets): WB ^{18}F-FDG 1481.3 (76.1-7700.9), WB ^{11}C-Choline 2451.9 (290.9-5023.1), WB ^{68}Ga-DO-TATOC 1161.8 (41.0-3728.4) and Head ^{11}C-Methionine 766.7 (52.3-2326.9). Mean effective doses (mSv) were: WB ^{18}F-FDG 15.2±4.9, WB ^{11}C-Choline 26.4±5.6, WB ^{68}Ga 13.0±3.4 and Head ^{11}C-Methionine 1.9±3.1. Mean administered activities (MBq) and effective doses (mSv) for radiopharmaceuticals used in PET were: WB ^{18}F-FDG 333.9-6.4, Head ^{11}C-Methionine 295.6-2.5, WB ^{68}Ga-DOTATOC 168.2-3.5 and WB ^{11}C-Choline 322.2-1.5. The mean total effective doses (mSv) due to both modality were: WB ^{18}F-FDG 21.5±5.2, Head ^{11}C-Methionine 4.4±3.1, WB ^{11}C-Choline 27.9±5.9 and WB ^{68}Ga-DOTATOC 16.5±3.5. **Conclusions:** The implementation of a dose tracking system to nuclear medicine is of great value for accurate and regular recording, reporting and analysis of patient's effective doses. It can help to improve the evaluation of radiation exposures in the clinical practice.

M2M: Prostate Cancer Targeting

OP-487

In vitro and in vivo characterization of a [^{18}F]AlF-labeled PSMA ligand for imaging of PSMA-expressing xenografts

S. Lütje[1,2], G. M. Franssen[1], M. Gotthardt[1], K. Herrmann[2], O. C. Boerman[1], S. Heskamp[1]; [1]Dept. Radiology and Nuclear Medicine, Radboud university medical center, Nijmegen, NETHERLANDS, [2]Clinic for Nuclear Medicine, University Hospital Essen, Essen, GERMANY.

Aim: The aim of this study was to compare the PSMA-targeting characteristics of [^{18}F]AlF-PSMA-11, radiolabeled based on chelation of [^{18}F]AlF, to those of ^{68}Ga-PSMA-11 to image PSMA-expressing xenografts with PET/CT. **Materials and Methods:** Labeling of [^{18}F]AlF-PSMA-11 via [^{18}F]AlF-complexation was performed as described by Boschi et al.. Several conditions for the quality control of the labeling of PSMA-11 via [^{18}F]AlF-complexation were evaluated to characterize the influence of ethanol, acetonitrile, and TFA on the stability of the labeled product. Internalization of [^{18}F]AlF-PSMA-11 was compared to ^{68}Ga-PSMA-11 using PSMA-expressing LNCaP tumor cells. In vivo biodistribution of [^{18}F]AlF-PS-MA-11 (0.26 nmol/mouse, 8-9 MBq/mouse) was compared to ^{68}Ga-PSMA (0.26 nmol/mouse, 7-8 MBq/mouse) in male BALB/c nude mice with PSMA-expressing s.c. LS174T-PSMA tumors by ex vivo biodistribution studies and PET/CT imaging (1 and 2 h p.i.). **Results:** In contrast to ^{68}Ga-PSMA-11, [^{18}F]AlF-PSMA-11 was not stable in PBS, TFA, ethanol and acetonitrile (radiochemical purity in PBS: 64.5% at purification - 52.7% at 120 min post purification). However, [^{18}F]AlF-PSMA-11 remained relatively stable in 25 mM NH$_4$OAc pH 6.9. Radiochemical purity was 98.5 %, 96.3%, 94.7%, 92.5% at 0, 60, 120, and 180 min post purification, respectively. Internalization of both compounds in vitro in LS174T-PSMA cells was comparable, increasing from 5.7±0.5 % at 30min incubation time to 10.8±0.4 % at 120min incubation time and 5.2±0.5 % at 30min incubation time to 13.8±0.7 % at 120min incubation time for [^{18}F]AlF-PSMA-11 and ^{68}Ga-PSMA-11, respectively. Highest tumor uptake was observed at 1h p.i. reaching 14.7±7.6 %ID/g and 10.4±2.3 %ID/g for [^{18}F]AlF-PSMA-11 and ^{68}Ga-PSMA-11, respectively. Tracer accumulation in the kidneys at 2h p.i. was significantly lower for [^{18}F]AlF-PSMA-11 (43.5±5.7 %ID/g) compared to ^{68}Ga-PSMA-11 (105.8±13.8 %ID/g). However, accumulation of [^{18}F]AlF-PSMA-11 in the bones ranged from 2.9±0.7 (1h p.i.) - 4.2±0.4 (2h p.i.) %ID/g. PSMA-expressing xenografts could be specifically visualized using both ^{68}Ga-PSMA-11- and [^{18}F]AlF-PSMA-11-PET/CT. **Conclusion:** [^{18}F]AlF-PSMA-11 shows similar internalization capacity and visualizes PSMA-expressing tumors with comparable tumor uptake as ^{68}Ga-PSMA-11. However, [^{18}F]AlF-PSMA-11 is not stable and considerable bone uptake might hamper visualization of bone lesions. Therefore, ^{68}Ga-PSMA-11 is superior to [^{18}F]AlF-PSMA-11 to image PSMA expressing tumors.

OP-488

Synthesis and Radiolabelling of a DOTA-Bisphosphonate-Conjugated PSMA Inhibitor

N. Pfannkuchen[1], F. Rösch[1], R. Bergmann[2]; [1]Institute of Nuclear Chemistry, Johannes Gutenberg University, Mainz, GERMANY, [2]Institute of Radiopharmaceutical Cancer Research, Helmholtz-Zentrum Dresden-Rossendorf, Dresden, GERMANY.

Introduction: Conjugates of bisphosphonates (BPs) with macrocyclic chelators already showed promising results for the diagnosis and radiotherapy of painful bone metastases which often occur as a consequence of prostate carcinomas. Since urea-based peptidomimetic inhibitors of the prostate-specific membrane antigen (PSMA) are widely investigated for diagnosis and therapy of metastatic prostate cancer, combination of both structures could provide a useful theranostic compound simultaneously binding to bone metastases by two mechanisms. Here we report on the synthesis and radiolabelling of a DOTA-based BP bearing the peptidomimetic glutamate-urea-lysine binding motif. **Subjects & Methods:** The BP-conjugated PSMA inhibitor was obtained in a 17 step synthesis and characterized by NMR and LC-MS. The DOTA-based BP was synthesized in 11 steps starting from cyclen. The peptidomimetic binding motif including a naphthylic linker was synthesized by solid-phase peptide chemistry in 4 steps followed by coupling of the DOTA-based BP, cleavage from the resin and deprotection. After purification by RP-HPLC the compound was labelled with n.c.a. ^{68}Ga. Radiochemical yields were determined by radio-TLC and radio-HPLC. Stability of the ^{68}Ga-complex was examined in PBS (pH 7.4) and human serum over 2 hours. **Results:** Radiolabelling of the new BP-conjugated PSMA inhibitor with ^{68}Ga in sodium acetate buffer (0.2 M, pH 4.5) provided radiochemical yields ≥95 % within 15 minutes at 95 °C. The ^{68}Ga-labelled compound showed a stability of 93-99 % in PBS as injectable solution and human serum. **Conclusion:** Successful synthesis of a BP-conjugated PSMA inhibitor and radiolabelling with ^{68}Ga as well as ongoing labelling studies with ^{177}Lu are the first steps towards a new theranostic compound for diagnosis and therapy of bone metastases as a consequence of prostate cancer. The potential of this compound will now be examined *in vivo* in biodistribution studies as well as small animal PET imaging. Ideally, we may expect an increased accumulation of the new tracer in comparison to the individual tracers, i.e. the DOTA-PSMA derivative and the DOTA-BP derivative, respectively.

OP-489

Synthesis and evaluation of ^{18}F-labeled trifluoroborate derivatives of PSMA-617 for imaging prostate cancer with positron emission tomography

H. Kuo[1], J. Pan[1], H. Merkens[1], J. Lau[1], C. Zhang[1], N. Colpo[1], D. M. Perrin[2], K. Lin[1], F. Bénard[1]; [1]BC Cancer Research Centre, Vancouver, BC, CANADA, [2]University of British Columbia, Vancouver, BC, CANADA.

Aim: Prostate-specific membrane antigen (PSMA) is a glycoprotein overexpressed on the surface of prostate cancer cells, and represents a promising imaging biomarker for diagnosis of prostate cancer. ^{18}F-DCFPyL is currently the most popular PSMA-targeting clinical PET tracer radiolabeled with ^{18}F that can be produced in a large scale and suitable for regional distribution. However, production of ^{18}F-DCFPyL is not trivial, and involves multiple synthesis steps. In this study, we designed, synthesized and evaluated two ^{18}F-labeled PSMA-617 derivatives for prostate cancer imaging, and compared them with ^{18}F-DCFPyL. Both tracers contain an ammoniomethyl-trifluoroborate (AmBF$_3$) motif that can be radiolabeled with ^{18}F via a single ^{18}F-^{19}F isotope exchange reaction directly in aqueous solution. **Methods**: The core peptidomimetic structure containing Glu-ureido-Lys, 2-naphthylalanine, and linker (4-(aminomethyl) cyclohexanecarboxylic acid for HTK01157, or 9-amino-4,7-dioxanonanoic acid for HTK01146) was constructed on solid phase. 2-Azidoacetic acid was coupled to the *N*-terminus. Azide-containing intermediates were cleaved from the resin, and reacted with *N*-propargyl-*N,N*-dimethylammoniomethyl-trifluoroborate to yield HTK01157 and HTK01146. The stability of tracers was assessed in mouse plasma and LogD$_{7.4}$ values were determined by the shake-flask method. PET imaging and biodistribution studies were conducted in mice bearing PSMA-expressing LNCaP prostate cancer xenografts. **Results**: ^{18}F-HTK01157 and ^{18}F-HTK01146 were obtained in 17±13% (n=2) and 13±7% (n=3) decay-corrected radiochemical yields with >99% radiochemical purity. Specific activities for ^{18}F-HTK01157 and ^{18}F-HTK01146 were 137±22.2 and 92.5±22.2 GBq/µmol, respectively. Both tracers were stable in mouse plasma without noticeable degradation after 2h incubation, and were highly hydrophilic (LogD$_{7.4}$: -3.52±0.21 for ^{18}F-HTK01157 and -3.24±0.03 for ^{18}F-HTK01146). All tracers enabled clear visualization of LNCaP tumours in PET images with ^{18}F-HTK01157 exhibiting higher tumour uptake (12.1±2.93 %ID/g) than ^{18}F-DCFPyL (7.95±1.64 %ID/g) and ^{18}F-HTK01146 (5.09±1.10 %ID/g) at 1 h post-injection. Tumour-to-blood and tumour-to-muscle ratios of ^{18}F-HTK01157 (17.1±5.4 and 49.7±28.5) and ^{18}F-DCFPyL (26.1±3.33 and 46.8±18.3) were comparable. Despite lower tumour uptake, the tumour-to-background ratios of ^{18}F-HTK01146 (T/B: 54.6±38.5; T/M, 117±52.1) were ~2-folds higher than ^{18}F-DCFPyL due to its faster clearance from nontarget tissues. Co-injection with DCFPyL (0.5 mg) reduced >95% uptake of ^{18}F-HTK01157 and ^{18}F-HTK01146 in tumours, demonstrating uptake was PSMA-mediated. **Conclusion**: We successfully synthesized and evaluated ^{18}F-HTK01157 and ^{18}F-HTK01146 for PSMA-targeted imaging. Both tracers clearly delineated LNCaP prostate cancer xenografts in PET images, and showed comparable (for ^{18}F-HTK01157) or even better (for ^{18}F-HTK01146) tumour-to-background contrast than ^{18}F-DCFPyL. With the advantage of facile preparation via a single ^{18}F-^{19}F isotope exchange reaction, ^{18}F-HTK01157 and ^{18}F-HTK01146 warrant further development for clinical translation for prostate cancer imaging.

OP-490

First-in-human PET/CT imaging with ^{152}Tb-DOTATOC in neuroendocrine neoplasm and of prostate cancer using ^{152}Tb-PSMA-617

A. Singh[1], R. P. Baum[1], D. Müller[1], S. Senftleben[1], M. Benesova[2,3], C. Vermeulen[2], S. Gnesin[4], U. Köster[5], K. Johnston[6], H. R. Kulkarni[1], A. Türler[7,8], R. Schibli[2,3], J. O. Prior[4], N. P. van der Meulen[2,7], C. Müller[2,3]; [1]Theranostics Center for Molecular Radiotherapy and Molecular

Imaging, Bad Berka, GERMANY, [2]Center for Radiopharmaceutical Sciences ETH-PSI-USZ, Paul Scherrer Institut, Villigen-PSI, SWITZERLAND, [3]Department of Chemistry and Applied Biosciences, ETH Zurich, SWITZERLAND, [4]Department of Nuclear Medicine and Molecular Imaging, Lausanne University Hospital (CHUV), Lausanne, SWITZERLAND, [5]Institut Laue-Langevin, Grenoble, FRANCE, [6]ISOLDE/CERN, Meyrin, SWITZERLAND, [7]Laboratory of Radiochemistry, Paul Scherrer Institut, Villigen-PSI, SWITZERLAND, [8]Department of Chemistry and Biochemistry, University of Bern, Bern, SWITZERLAND.

Objective: The lanthanide Terbium comprises several medically very interesting radionuclides for molecular imaging ([152/155]Tb) and targeted radionuclide therapy ([149/161]Tb). [152]Tb ($T_{1/2}$ = 17.5 h, $E\beta^+_{av}$ = 1140 keV, I = 20%) is suitable for PET imaging and may play a role for diagnosis and in dosimetry prior to radionuclide therapy (RNT) using radiolanthanides. The aim of this first-in-human study was to assess the suitability of [152]Tb for molecular imaging of neuroendocrine neoplasms (NEN) and prostate cancer (PCa). **Methods:** [152]Tb was produced by proton irradiation of a tantalum target, followed by on-line mass separation at ISOLDE-CERN and purification at PSI-Villigen. [152]Tb was transported >600 km to Zentralklinik Bad Berka, Germany, where radiolabeling was performed by incubating DOTATOC or PSMA-617, respectively with [152]Tb at 95°C for 15 minutes. Patient 1 (P1) with an ileum NEN was injected with [152]Tb-DOTATOC (143 MBq) and PET/CT images were acquired up to 24h p.i. Patient 2 (P2), suffering from metastatic PCa was administered [152]Tb-PSMA-617 (150 MBq) and PET/CT images were acquired up to 25h p.i. **Results:** Radiochemical yields for DOTATOC and PSMA-617 were >97% each, with specific activity = 1.37 MBq/nmol and 0.44 MBq/nmol, respectively. In P1, [152]Tb-DOTATOC PET/CT images demonstrated specific tracer uptake in lymph node, liver and skeletal metastases, with excellent retention up to 24h p.i. Physiological uptake was seen in the pituitary gland, liver, spleen, intestines, and kidneys as well as excretion of tracer in the urinary bladder. In P2, [152]Tb-PSMA-617 PET/CT allowed visualization of small lymph node and bone metastases up to 25h p.i. Physiological uptake was seen in lacrimal and salivary glands, liver, spleen, intestines, kidneys, as well as excreted activity in the urinary bladder. In comparison with previous PET/CT studies using ^{68}Ga-DOTATOC and ^{68}Ga-PSMA-617, respectively, no new metastases were identified. No adverse effects were observed after administration of [152]Tb in either case. **Conclusion:** This first-in-human studies show significant potential of [152]Tb-based PET/CT imaging in NEN and PCa. [152]Tb could be particularly useful for performing pre-therapeutic dosimetry prior to ^{177}Lu-based RNT as it allows PET imaging up to at least 25 h. Future studies could be planned with administration of larger injected activities followed by PET image acquisition performed at even more delayed timepoints. The longer half-life of [152]Tb has the advantage of its distribution over large areas as well. Currently, routine clinical application of [152]Tb is restricted due its limited availability.

Low molecular weight target module for PET imaging and UniCAR T cell immunotherapeutic treatment of PSMA expressing tumors

R. Bergmann[1], A. Feldmann[1], M. Schäfer[2], C. Liolios[3], S. Koristka[1], N. Berndt[1], K. Kuhne[1,4], A. Höpping[5], J. Pietzsch[6,7], J. Kotzerke[8], J. Steinbach[1], K. Kopka[2,9], M. Bachmann[1,10,11]; [1]Helmholtz-Zentrum Dresden-Rossendorf, Institute of Radiopharmaceutical Cancer Research, Dresden, GERMANY, [2]Deutsches Krebsforschungszentrum, Abteilung Radiopharmazeutische Chemie, Heidelberg, GERMANY, [3]Deutsches Krebsforschungszentrum, Heidelberg, GERMANY, [4]Technische Universität Dresden, Fachrichtung Chemie und Lebensmittelchemie, Dresden, GERMANY, [5]ABX GmbH, Radeberg, GERMANY, [6]Helmholtz-Zentrum Dresden-Rossendorf, Dresden, GERMANY, [7]Technische Universität Dresden, Fachrichtung Chemie und Lebensmittelchemie, Dresden, GERMANY, [8]Technische Universität Dresden, Uniklinikum 'Carl Gustav Carus,' Klinik und Poliklinik für Nuklearmedizin, Dresden, GERMANY, [9]National Center for Tumor Diseases, Heidelberg, GERMANY, [10]Technische Universität Dresden, Uniklinikum 'Carl Gustav Carus,' UCC, Tumorimmunology, Dresden, GERMANY, [11]National Center for Tumor Diseases, 'Carl Gustav Carus' TU Dresden, Dresden, GERMANY.

Introduction: Novel PET diagnostic and immunotherapeutic treatment options, particularly for solid tumors including prostate cancer are urgently needed. The retargeting of chimeric antigen receptors transfected T cells by antibodies can cause severe adverse effects. This treatment can easily become life threatening, especially due to "on" or "off" target side effects. To overcome these problems, we recently introduced a modular CAR technology termed UniCAR: UniCAR T cells are inert but can reversibly "turn on" by application of a target module (TM). After elimination of the TM UniCAR T cells automatically "turn off". Therefore, the bioavailability of the TM determines the activation state of the UniCAR T cells. The molecular mass and consequently the blood clearance of the TM represent the main parameter of this "turn on/off" process. For proof of concept we therefore tried to convert the low molecular weight PSMA ligand PSMA-HBED-CC into a TM for in vivo imaging. **Methods:** The synthesis of HBED-CC-PSMA-E5B9 (PSMA-TM) was developed and realized at DKFZ, radiolabeling with ^{68}Ga was performed at HZDR. The radiochemical yield and purity were analyzed by radio-HPLC. Preclinically, the retargeting efficiency of ^{68}Ga-PSMA-TMwith UniCAR T cells was tested by means of cell binding assays, biodistribution experiments as well as dynamic PET imaging and metabolite analysis in LNCaP-PSCA-Luc tumor bearing mice *in vitro* and *in vivo*. Moreover, a first-in-man PET/CT study with ^{68}Ga-labelled PSMA-TM was carried out. **Results:** PSMA-TM successfully was labeled with ^{68}Ga resulting in almost quantitative radiochemical yields (&gt98%) and molar activities of 10 to 60 GBq/micromol. Tumor-to-muscle ratios of 54 plusminus 20 were reached after 2 h with SUVmean of 1.2 plusminus 0.5 in the tumor-bearing mice. Specificity of tracer-associated tumor uptake was determined by blocking with PSMA-11, 2-PMPA, and by comparison with PC3 tumors. Successful cell killing efficiency was demonstrated in vitro and in s.c. LNCaP-PSCA-Luc mouse model by optical imaging. The in vivo tumor accumulation was compared with that of ^{68}Ga-PSMA-11 which showed a similar distribution pattern. **Conclusion:** The

small molecule based PSMA-TM could be used for both retargeting of UniCAR T cells to PSMA expressing cells in vitro and in tumor-bearing mouse models, and for PSMA-11 analog PET imaging in mice, which could also be confirmed by a first-in-man study. In conclusion, the novel theranostic low molecular weight molecule HBED-CC-PSMA-E5B9 can be considered as useful PET imaging agent to non-invasively follow the progress of individualized PSMA-directed immunotherapeutic tumor treatment with the UniCAR T cell system.

OP-492
89Zr-df-IAB2M for PET/CT imaging of prostate cancer

J. S. Batra, Y. S. Jhanwar, S. Vallabhajosula, M. J. Niaz, T. Flynn, S. T. Tagawa, N. H. Bander, D. S. Scherr; Weill Cornell Medicine, New York, NY, UNITED STATES OF AMERICA.

Background: Prostate-specific membrane antigen (PSMA) is a cell surface antigen that is highly restricted to and overexpressed in prostate cancer (PC). IAB2M is an anti-PSMA minibody, derived from the humanized J591 mAb, that can be labeled with Zirconium-89 (^{89}Zr) for use as a PET radioligand. Unlike small molecule PSMA ligands that are excreted via the urinary tract which can compromise visualization of lesions within the prostate gland and pelvis, IAB2M is excreted by a hepatic route. We are conducting a Phase 2a clinical trial to image PC patients with clinically localized disease prior to their scheduled prostatectomy. **Aim:** To evaluate the ability of ^{89}Zr-df-IAB2M to detect localized, clinically significant PC, defined as: ≥ 0.5 cm^3 with Gleason pattern ≥ 4, within the gland. As a secondary endpoint, extra-prostatic uptake would also be evaluated and correlated with any available surgical tissue. **Materials and Methods:** Patients with a diagnosis of localized PC who plan treatment by radical prostatectomy are eligible for this study. Each received 10 mg of df-IAB2M conjugated with 2.5 mCi of ^{89}Zr and were scanned 2 - 4 days later at their convenience. PET/CT images were reviewed by a nuclear medicine physician. Findings were compared with conventional imaging modalities and the histopathological findings of the post-prostatectomy specimen. **Results:** To date, 9 men with median age 62 years (range 48 - 72) were enrolled between January to March 2017. Pre-surgery median PSA was 8 ng/mL (range 3.9 - 36.56), 89% had Gleason score (GS) ≥ 7 (range 6 - 9), perineural invasion (PNI) and seminal vesicle invasion (SVI) present in 25% and 12.5%, respectively. 89% had PIRADS category ≥ 4 lesions on mpMRI. Excellent targeting of PC lesions by ^{89}Zr-df-IAB2M PET/CT imaging in the prostate gland as well as in the lymph nodes has been seen. Upon radical prostatectomy, histopathology of the surgical specimen confirmed 86% had GS ≥ 7 (range 6 - 9) with visualized extra-prostatic extension in 71%, lymph node involvement, PNI and SVI each in 43% patients. No adverse events have occurred. 11 more subjects will be enrolled/imaged in this study. **Conclusion:** ^{89}Zr-df-IAB2M is safe to administer and provides favorable targeting of PC lesions within the prostate gland as well distant disease. We plan to enroll an additional 11 subjects over the next 3 months and final assessment of lesion targeting will be analyzed and presented at the meeting.

OP-493
Comparative biodistribution of the parental murine monoclonal antibody 5A10 and its humanized version for PSA-targeting in prostate cancer

T. Tran; Dept of Radiopharmacy, Stockholm, SWEDEN.

Aims: The murine IgG$_1$ antibody m5A10 targeting PSA, prostate-specific antigen, expression has earlier been evaluated by our group and was found to be a good candidate for diagnosing of prostate cancer (PCa) lesions. For future clinical studies, we developed a humanized version of 5A10 antibody and investigated the targeting properties of the newly h5A10 in PCa xenografts. The biodistribution of the parental murine 5A10 was compared with the humanized version. **Materials and Methods:** The murine and humanized 5A10 antibodies were conjugated with CHX-A''-DTPA and labeled with ^{111}In. Affinity measurements using Biacore technology were performed before and after DTPA conjugation. Micro-SPECT imaging was performed in PSA- positive LnCAP prostate-cancer xenografts at 24, 48, 72 and 168 h post-injection (hpi). Region of interest (ROI) analysis in the images were performed to determine the image contrast. Organs were collected at the last time point and measured on a gamma counter to estimate the tumor targeting properties of ^{111}In-5A10. **Results:** Conjugation of the antibodies does not appear to affect the affinity noticeably since the affinity, K$_D$, was not significantly changed. The affinities were in the range of 10-20 pM. Comparison of the biodistribution data for the humanized ^{111}In-DTPA-h5A10 with that for the parent murine antibody ^{111}In-DTPA-m5A10 revealed an unexpected and advantageous difference. The tumor accumulation was significantly higher for the humanized than for the murine, with 7.4 $\pm$ 1.4 %IA/g for h5A10 compared to 2.7 $\pm$ 0.75 %IA/g for m5A10 (p <0.001) at 7 days p.i. **Conclusions:** The humanized antibody ^{111}In-h5A10 effectively targets prostate tumours *in vivo* and exhibits an unexpectedly better tumor accumulation than its murine antibody. These findings provide compelling evidence of the better targeting properties of humanized 5A10 antibodies in the diagnosis and likely better therapeutic efficacy in the treatment of prostate cancer. **Research Support:** Swedish Cancer Foundation, Swedish Research Council, Mrs. Bertha Kamprad Foundation and Percy Falk's Foundation.

OP-494
GRPR-Targeted Radiotherapy: Influence of Chelator on Labeling and Biodistribution of Four ^{177}Lu-Labeled Analogues of the GRPR-Antagonist PEG2-RM26

A. Orlova[1], B. Mitran[1], T. Maina[2], B. A. Nock[2], S. S. Rinne[1], V. Tolmachev[1], U. Rosenström[1]; [1]Uppsala University, UPPSALA, SWEDEN, [2]INRASTES NCSR "Demokritos", Athens, GREECE.

Purpose: Gastrin releasing peptide receptors (GRPR) are overexpressed in primary prostate cancer (PCa) and soft tissue metastases. Radiolabeled GRPR-antagonists show high receptor affinity binding without physiological action, while displaying rapid renal clearance and low degree of renal reabsorption. These features

are promising for selective delivery of therapeutic radiotoxic loads to PCa lesions using suitable GRPR-antagonists as radionuclide carriers. The aim of this study was to optimize the GRPR-antagonist PEG2-RM26 for labelling with ^{177}Lu and further preclinical evaluation in a PCa model. **Methods**: The PEG2-RM26 analogue was coupled to NOTA, NODAGA, DOTA and DOTAGA and these peptide-conjugates were labelled with [177]Lu.The receptor affinity, ^{177}Lu-chelate stability, and biodistribution profile of resulting radiopeptides were studied in PC-3 xenografted mice. The in vivo metabolic stability of ^{177}Lu-NOTAGA/DOTA/DOTAGA-PEG2-RM26 was tested by HPLC analysis of peripheral mouse blood samples collected 5 min postinjection (pi) of each radiopeptide alone (control) or with coinjection of the neutral endopeptidase (NEP)-inhibitor phosphoramidon (PA). **Results**: Conjugates were labelled with ^{177}Lu in high yields (96±3% for NOTA and almost quantitative yields for the others). Affinities to GRPR of bioconjugates were found independent of chelator type in the subnanomolar range. After 1 h incubation at 37°C in mouse blood plasma 16±2% release of radioactivity was determined for the NOTA-conjugate, 4.3±0.7% for the NODAGA-conjugate and 1.5% for the DOTA/DOTAGA-conjugates. Due to the low ^{177}Lu-chelate stability, ^{177}Lu-NOTA-PEG2-RM26 was excluded from further characterisation. In vivo, 71±3% of ^{177}Lu-DOTAGA-PEG2-RM26 remained intact at 5 min pi, while 64-65% of ^{177}Lu-DOTA-PEG2-RM26 and ^{177}Lu-NODAGA-PEG2-RM26 remained intact within this period. Treatment of mice with PA resulted in full stabilization of the radiopeptides in vivo. The biodistribution of the three analogues was studied at 1 and 24 h pi in PC-3 model non-treated with PA, showing rapid renal clearance. Tumour-to-blood ratios were >15 1 h pi and tumour-to-kidney ratios were 1.3±0.2 for NODAGA, 3±1 for DOTA, and 2.8 ±0.6 for DOTAGA radioligands at 1 h pi, significantly increasing to 2.1±0.5, 5±1 and 3.0±0.3, respectively, at 24 h pi. Although the biodistribution pattern was similar for the three radiopeptides, overall results of in vivo characterisation point ^{177}Lu-DOTAGA-PEG2-RM26 as the most promising radionuclide carrier. **Conclusions**: Based on in vitro and in vivo characterisation of the four ^{177}Lu-labeled PEG2-RM26 analogues we concluded that ^{177}Lu-DOTAGA-PEG2-RM26 is the most promising member of the series for further evaluation as a candidate for GRPR-targeted radionuclide therapy of PCa. The impact of PA-treatment on therapy outcome will be also investigated.

[18]F-fluciclovine PET/MRI in the evaluation of brain glioma

A. Karlberg[1,2], E. M. Berntsen[1,2], H. Johansen[1], M. Myrthue[1], A. J. Skjulsvik[3,4], I. Reinertsen[5,6], M. Esmaeili[2], H. Y. Dai[3], Y. Xiao[7,8], H. Rivaz[7,8], P. Borghammer[9], O. Solheim[5,10,11], L. Eikenes[2]; [1]Department of Radiology and Nuclear Medicine, St. Olavs University Hospital, Trondheim, NORWAY, [2]Department of Circulation and Medical Imaging, Norwegian University of Science and Technology, Trondheim, NORWAY, [3]Department of Pathology and Medical Genetics, St. Olavs University Hospital, Trondheim, NORWAY, [4]Department of Laboratory Medicine, Children's and Women's Health, Faculty of Medicine, Norwegian University of Science and Technology, Trondheim, NORWAY, [5]Norwegian National Advisory Unit for Ultrasound and Image Guided Therapy, St. Olavs University Hospital, Trondheim, NORWAY, [6]Department of Medical Technology, SINTEF, Trondheim, NORWAY, [7]PERFORM Centre, Concordia University, Montreal, QC, CANADA, [8]Department of Electrical and Computer Engineering, Concordia University, Montreal, QC, CANADA, [9]Department of Nuclear Medicine & PET Centre, Aarhus University Hospital, Aarhus, DENMARK, [10]Department of Neurosurgery, St. Olavs University Hospital, Trondheim, NORWAY, [11]Department of Neuroscience, Norwegian University of Science and Technology, Trondheim, NORWAY.

Aim: The aim of this ongoing study is to improve the diagnostic accuracy and treatment planning of brain glioma using hybrid PET/MRI technology. Structural MRI and histopathological tissue sampling are routinely done as part of the diagnostic work-up of glioma patients today. Due to the heterogeneous nature of gliomas, there is however a risk of undergrading caused by histopathological sampling errors. MRI has limitations in identifying tumor grade and type, detecting diffuse invasive growth, and separating recurrences from treatment-induced changes. PET can provide quantitative information of cellular activity and metabolism, and may therefore have additional value compared to MRI alone. **Materials and Methods:** 5 pre-operative patients with suspicion of low- or high grade glioma have been included in this study. 45-minute PET list-mode acquisitions were performed simultaneously to the ordinary MRI acquisition using the amino acid PET tracer ^{18}F-fluciclovine (FACBC). Fused PET/MRI and intraoperative 3D ultrasound images were used to guide

surgical resection and histopathological tissue sampling in flu-ciclovine-avid tumors. Image-localized histopathological samples were extracted from the tumors before resection (when possible). Analyses of the samples were related to PET/MRI image data to assess the additional value of ^{18}F-fluciclovine-PET. **Results:** Histopathological examination revealed two grade II, one grade III and two grade IV tumors according to the 2016 WHO Classification of Tumors of the CNS. ^{18}F-fluciclovine uptake was present in grade III and grade IV tumors. No PET uptake was seen in grade II tumors (or grade II parts). Tumor-to-background ratio ($SUV_{max\ tumor}/SUV_{mean\ bg}$) was 3.4 for the grade III tumor and 19.2 and 25.0 for the grade IV tumors respectively. **Conclusion:** ^{18}F-fluciclovine uptake was highest where tumor grade, cell density, and cell proliferation were highest. This suggests that combined PET/MRI with this tracer has potential to improve accuracy in histopathological tissue sampling and grading. Of note, the tumor-to-background ratios in high grade tumors were considerably greater than that seen with other amino acid PET tracers, including ^{11}C-methionine and ^{18}F-FET. No PET uptake in grade II tissue might indicate that ^{18}F-fluciclovine is less suited for tumor delineation in lower grade gliomas.

OP-499

Immunohistochemically evaluated PSMA expression in 122 treatment naive glioma patients related to [^{11}C]-methionine PET and survival

T. Traub-Weidinger, N. Poetsch, T. Bachnik, A. Woehrer, J. Gesperger, W. Wadsak, M. Markus, M. Preusser, M. Hacker, O. Koperek; MEDICAL UNIVERSITY OF VIENNA, Vienna, AUSTRIA.

Background: Apart from its expression in benign and malign prostate tissue, prostate specific membrane antigen (PSMA) was shown to be also expressed in endothelium of neovascularization in solid tumors. **The aim** of this study was to evaluate immunohistochemically the PSMA expression in glioma tissue and its relation to [^{11}C]-methionine (MET) PET and survival. **Methods:** A total of 122 treatment-naive glioma patients (67 men, 55 women, mean age: 45, range 18 - 84 years) who underwent biopsy or tumor resection were included in this study. Immunohistochemical staining (IHC) for PSMA expression was performed on the paraffin embedded tissue samples and analyzed for vascular as well as non-vascular staining. Additionally, IHC for isocitrate dehydrogenase 1-R132H (IDH1-R132H) mutation was performed. IHC results were then related to the pre-therapeutic semiquantitative MET PET and patients' survival. **Results:** PSMA expression on the vessels was observed in 26 of 122 samples. Vascular PSMA expression was specific for high grade gliomas (HGG) with positive vessel staining in 81 % of glioblastomas multiforme (GBM; n=21), 10% of WHO grade III (n=4, 1 astrocytoma [AC], 3 oligodendroglial tumors [ODG]) and just 2 % of grade II gliomas (n=1, AC). No significant differences between HGG and low grade gliomas (LGG) as well as between ODG and AC were seen in quantity of PSMA staining of non-vascular cells (mean amount of PSMA staining cells: HGG: 22; LGG: 20; ODG: 26; AC: 18). Analyzed based on the IDH1-R132H mutation status, significantly higher amounts of gliomas without verifiable IDH1-

R132H mutation (NOS) showed vascular PSMA expression (p < 0.001; 35 % of NOS, 6 % of IDH1-R132H mutated). Moreover, significantly shorter median survival times were seen for patients with vascular PSMA staining in all tumors as well as HGG only (p < 0.001; OR 7.7 and 4.8). Additionally, significantly higher mean T/N ratios by MET PET were found in patients with vascular PSMA staining compared to those without (mean T/N ratio values 4.17 and 2.47, p < 0.001). **Conclusion:** Vascular PSMA expression was seen as a high grade specific feature associated with higher T/N ratio values and shorter survival times.

OP-500

Improved detection of postoperative remaining meningioma tissue with 68Ga-DOTATATE PET/CT scans compared to surgeon's estimated Simpson Grade

F. J. Vettermann[1], M. Ueberschaerr[2], M. Unterrainer[1], P. Bartenstein[1], J. Tonn[2], C. Schichor[2], N. L. Albert[1]; [1]Department of Nuclear Medicine, Ludwig-Maximilians-University, Munich, GERMANY, [2]Department of Neurosurgery, Ludwig-Maximilians-University, Munich, GERMANY.

Purpose/Introduction: The intraoperatively assessed Simpson Grade (SG) describes the extent of surgical resection of meningiomas and has been identified as prognostic marker for recurrence. However, the validity of the scoring system in contemporary neurosurgical practice has recently been doubted. Moreover, ^{68}Ga-DOTATATE PET/CT scan has been shown to be a sensitive tool for detection of meningioma tissue. Thus, we investigated the congruence between the intraoperatively estimated SG and the postoperative ^{68}Ga-DOTATATE PET/CT. **Methods:** 37 adult patients were retrospectively identified with microsurgery of either newly diagnosed or recurrent meningioma and early postoperative ^{68}Ga-DOTATATE PET/CT scans (within 30 days) between January 2011 and July 2016. The PET parameters SUV_{max}, SUV_{mean} and threshold-based biological tumor volume (BTV; SUV>2.3) were correlated with the SG (complete removal with resection (I) or coagulation (II) of dural attachment, III: complete removal without coagulation or resection of dural attachment, IV: subtotal resection, V: decompression/biopsy only). **Results:** There were 4 SG I, 4 SG II, 4 SG III and 25 SG IV resections according to surgeon's estimate. Among the cases with SG I and II, only 3/8 showed no pathological uptake, while 5/8 presented with high tracer uptake typical for meningioma tissue (3/4 SG I: median SUV_{max}=14.7; SUV_{mean}=5.06; BTV=11.5 cm^3, and 2/4 SG II: median SUV_{max}= 8.0; SUV_{mean}= 3.8; BTV=5.4 cm^3). Of the SG III cases, all 4 showed pathological ^{68}Ga-DOTATATE uptake, but 2/4 with relatively low uptake intensity and volumes (SUV_{max}= 2.6 and 2.4; BTV=0.03 and 0.02 cm^3). All 25 SG IV resected cases had high uptake of ^{68}Ga-DOTATATE (median SUV_{max}= 23.2; SUV_{mean}=6.4) with a wide range of remaining tumor volume (median BTV 21.6 cm^3; range 2.7-101.2 cm^3). **Conclusion:** ^{68}Ga-DOTATATE PET/CT seems to provide more sensitive information to delineate postoperative remaining meningioma tissue especially in cases with resection according to SG I and II. The association of postoperative ^{68}Ga-DOTATATE PET/CT with prognosis and its potential influence on patient management is currently being investigated in a prospective longitudinal study.

OP-501

Impact of chemotherapy with Temozolomide on physiological brain 18F-DOPA uptake in patients with glioma

L. Carideo[1], F. Cicone[1], C. Scaringi[2], I. Russo[2], G. Minniti[2], F. Scopinaro[1]; [1]Nuclear Medicine Unit, Sant'Andrea Hospital, Sapienza University of Rome, Italy, Rome, ITALY, [2]Radiotherapy Unit, Sant'Andrea Hospital, Sapienza University of Rome, Italy, Rome, ITALY.

Purpose: To investigate the effects of temozolomide chemotherapy on the physiological uptake of 18F-DOPA. **Subjects and Methods**: The analysis included 155 consecutive studies from 121 patients with glioma referred for F-DOPA PET/CT at our institution between July 2010 and February 2017. Patients had been previously treated with surgery, temozolomide chemotherapy, stereotactic radiotherapy, or a combination thereof. To obtain the average background uptake (SUVbckr), a large hemispherical ROI including both gray and white matter was placed above the lateral ventricles, controlateral to the tumor lesion. A semi-automatic threshold-based VOI segmentation tool (Hermes Medical Solutions) was used to delineate tumor (>1.6 x background uptake) and controlateral basal ganglia (>2.0 x background uptake). In some cases manual adjustment was needed. Average tumor and basal ganglia uptakes (SUVt and SUVbg, respectively) were calculated within each given VOI. Tumor-to-background (TBR) and tumor-to-basal-ganglia (TBG) ratios were defined as SUVt/SUVbckr and SUVt/SUVbg, respectively. All studies were divided into three groups based on chemotherapy status: ongoing treatment (Group A, n=57); treatment completed >1 months before PET (Group B, n=50); no previous treatment (Group C, n=48). Differences between groups were assessed by ANOVA with Turkey's test for multiple comparisons. **Results:** There were significant effects of chemotherapy on SUVbckr and SUVbg (p=0.02 and p=0.05, respectively, ANOVA) In particular, mean SUVbckr was significantly lower in Group A than in Group B (1.005 ± 0.2458 vs 1.144 ± 0.309, p=0.01,Turkey's test), while the difference between Group A and Group C (1.067 ± 0.2099) was not significant (p=0.43, Turkey's test). As regards SUVbg, comparisons between Groups A (2.073 ± 0.4255) and B (2.262 ± 0.5684) and between Groups B and C (2.055 ± 0.3912) showed a trend towards significance (*p* values: 0.09 and 0.07 for A vs B and B vs C, respectively, Turkey's test). Prior radiotherapy had no effect on both SUVbckr and SUVbg (data not shown). In 92 patients with PET+ tumors, temozolomide chemotherapy affected TBR (and not TBG) (*p*=0.02, ANOVA). In particular, mean TBR was significantly higher in Group A than in Group B (2.374 ± 0.537, n=41 vs 2.093 ± 0.375, n=27; p=0.03, Turkey's test) **Conclusion:** Normal brain and basal ganglia F-DOPA uptake is decreased in patients with ongoing temozolomide. As a consequence, these patients appear to have increased TBR compared to patients who never underwent or already concluded chemotherapy. This has to be taken into account when interpreting F-DOPA PET images.

OP-502

IDH1-R132H mutation and semiquantitative [¹¹C]-methionine PET: Independent prognostic factors for characterization of newly diagnosed and treatment naive gliomas

N. Poetsch, A. Woehrer, J. Gesperger, A. R. Haug, D. Wilhelm, G. Karanikas, M. Weber, I. Rausch, M. Mitterhauser, W. Wadsak, M. Hacker, T. Traub-Weidinger; Vienna General Hospital, Vienna, AUSTRIA.

Purpose: Molecular alterations are one of the main modifications in the recently updated 2016 WHO classification of gliomas. Nevertheless, only few data exist regarding the association between those molecular parameters, such the isocitrate dehydrogenase (IDH) 1/2 mutation, and L-[S-methyl-¹¹C]methionine (MET) PET in glioma patients, with respect to prognosis. **Methods:** A total of 142 glioma patients (75 men, 67 women, mean age: 44, range 18 - 84 years) were included in this study, who underwent a MET PET prior to any therapy between 2000 and 2014 at the Medical University of Vienna. The IDH1-R132H mutation status was examined by immunohistochemical staining. PET scans were evaluated semiquantitatively by the SUV tumor to background (T/N) ratio and related to IDH1-R132H mutation status and patients' survival. **Results:** Mean follow-up was 48 ± 41 months, 49 patients died. IDH1-R132H mutation was observed in 75 patients, significantly positively influencing patient survival (p < 0.001, OR = 0.26), with a mean survival of 10.1 yrs. (range: 8,6 - 11,5 yrs) for IDH1-R132H mutated tumors and 5.4 yrs (range: 4,1 - 6,6 yrs) for patients without IDH1-R132H mutation, further specified as gliomas not otherwise specified (NOS). Considering MET PET data, a significant negative correlation between the IDH1-R132H mutation status and T/N ratio value was seen (p < 0.001, correlation coefficient: -0.3), with significantly higher T/N ratio values in NOS tumors than in IDH1-R132H mutated tumors (p < 0.001, T/N ratio values: 3.19 and 2.31). Additionally, multivariate testing showed tumor crossing midline, IDH1-R132H mutation status, therapy following surgery, Karnofsky score, surgical approach, T/N ratio value, age and parietal tumor localisation as independent prognostic parameters by decreasing order of significance (p = 0.001 to p = 0.038). **Conclusion:** This analysis of a large population of newly diagnosed gliomas demonstrates the IDH1-R132H mutation status as well as the T/N ratio value as independent prognostic parameters. Moreover, a significant negative correlation between the IDH1-R132H mutation status and the T/N ratio value was seen.

OP-503

Differential Diagnosis of Recurrence and Radiation Necrosis in High Grade Gliomas Using Multiparametric Analysis of Combined Dynamic O-(2-18F-fluoroethyl)-L-tyrosine PET and MRI

D. A. Hiob[1], C. Preibisch[2], J. Gempt[3], J. Schlegel[4], C. Straube[5], C. Zimmer[2], M. Schwaiger[1], T. Pyka[1]; [1]Department of Nuclear Medicine, Klinikum rechts der Isar der TU München, Muenchen, GERMANY, [2]Department of Neuroradiology, Klinikum rechts der Isar der TU München, Muenchen, GERMANY, [3]Department of Neurosurgery, Klinikum rechts der Isar der TU München, Muenchen, GERMANY, [4]Institute of Pathology and Neuropathology, Klinikum rechts der Isar

der TU München, Muenchen, GERMANY, [5]Department of Radiation Oncology, Klinikum rechts der Isar der TU München, Muenchen, GERMANY.

Introduction: Simultaneous FET-PET/MRI promises to improve diagnostics in the often difficult but clinically relevant differentiation between tumor recurrence and treatment related changes in high grade glioma patients. In this respect, dynamic FET-PET as well as MRI, e.g. diffusion and perfusion weighted imaging (DWI and PWI), have been used to obtain valuable information. In this study, we investigate their separate and added value in a combined protocol. **Methods:** 60 contrast-enhancing lesions suggestive of recurrence in 45 high grade glioma patients were identified in follow-up MRI after combined therapy. All patients received a dynamic FET scan of 40 minutes, as well as morphologic, perfusion- and diffusion-weighted MRI on a hybrid PET/MR scanner. Lesions were manually encircled by 2-cm-spheres. Further data analysis was performed using MATLAB with parameter extraction on 90% isocontour volumes in the respective regions. **Results:** 45 lesions were classified as recurrence, 15 as radiation necrosis. Gold standard for diagnosis was histology in 16 and follow-up imaging in 44 cases. At optimal cut-off, sensitivities and specificities for static PET were 83% and 85%, increasing to 86% and 85% when including dynamic imaging, 72% and 74% for PWI as well as 70% and 63% for DWI. When analyzing receiver-operating characteristics, AUC was 0.86 for PET, 0.74 for PWI and 0.63 for DWI. Multiparametric analysis using a linear combination of PET, PWI and DWI resulted in an AUC of 0.89, improving discrimination particularly when demanding high specificity (75% sensitivity vs. 53% sensitivity at 100% specificity). **Conclusion:** Simultaneous dynamic FET-PET/ MRI was reliably feasible for imaging of recurrent high-grade glioma. While the single modalities were able to discriminate between recurrence and treatment-related changes as expected, multiparametric analysis might be of value especially when high specificity for tumor progression is desired.

OP-504

Voxel-based analysis of dynamic ^{18}F-FET-PET in gliomas : association with IDH1 mutational status and survival.

P. Blanc-Durand[1], A. Van Der Gucht[1], A. Kourilsky[2], V. Dunet[1], A. Verger[3], K. Langen[4], M. Jreige[1], M. Nicod-Lalonde[1], N. Schaefer[1], J. Prior[1]; [1]CHUV, Lausanne, SWITZERLAND, [2]Beaujon, Paris, FRANCE, [3]CH, Nancy, FRANCE, [4]Forshungszentrum, Jülich, GERMANY.

Purpose: The prognostic impact of the isocitrate dehydrogenase (*IDH*) 1 mutation has been reported by several studies. Also, PET with ^{18}F-fluoro-ethyl-tyrosine (^{18}F-FET PET) has been increasingly used to evaluate patients with gliomas, however its prognostic value remains unclear. We aimed to investigate the association between dynamic ^{18}F-FET PET, *IDH1* mutation status and survival using a voxel-based approach. **Methods:** Fifty-two patients with newly diagnosed gliomas and dynamic ^{18}F-FET PET before any histopathologic investigation or treatment were retrospectively included. Each dynamic ^{18}F-FET PET image was realigned to the first image and spatially normalized in the MNI

template. A tumor mask was semi-automatically generated from the Z-score map. Each brain tumor voxel was clustered in 3 types of curve shape (curve #1: rapidly increasing followed by slowly decreasing slope, curve #2: slowly increasing slope, curve #3: rapidly increasing and rapidly decreasing slopes) using dynamic time warping and k-means clustering. The number of voxels of each of the 3 previous curves and the tumor % of each curve in brain tumors were compared between patients with mutated and wild-type *IDH1*. The prognostic value for progression free-survival (PFS) and overall survival (OS) of each curve's proportion; *IDH1* mutation status and tumor grade was integrated into a multivariate cox regression. **Results:** Thirty-seven dynamic ^{18}F-FET PET (18 low-grade and 19 high-grade gliomas) could be segmented and retained in the final analysis. Seventeen patients were *IDH1* mutant and 20 *IDH1* wild-type. Voxel-based analysis of dynamic ^{18}F-FET PET revealed that curve #2 was positively associated with the mutated *IDH1* status (P = 0.016) whereas curve #3 was negatively associated with the mutated *IDH1* status (P = 0.009). No difference was found with the curve #1 (P = 0.13). In a multivariate model, the curve #2 remained an independent positive prognostic factor for PFS (HR 0.15, 95% CI 0.02-0.76, P = 0.02) and OS (HR 0.06, 95% CI 0.01-0.54, P = 0.01). **Conclusion:** Voxel-based analysis of dynamic ^{18}F-FET PET revealed that the proportion of slowly increasing slope (curve #2) and the proportion of rapidly increasing and rapidly decreasing slopes (curve #3) were statistically associated with the *IDH1* mutation status. Also, the curve #2 was an independent positive prognostic factor for PFS and OS in multivariate analysis.

Cardiovascular System: Myocardial Perfusion PET - 13N-Ammonia and 15O-Water

OP-505

AMMO-X: A cross-comparison study of ^{13}N-ammonia PET MPQ software tools

S. V. Nesterov[1,2], L. E. Juárez-Orozco[1], R. J. Knol[3], R. Sciagrà[4], P. Slomka[5], A. Alessio[6], F. van der Zant[3], C. Han[1], N. Kartiosuo[7], J. M. Knuuti[1]; [1]Turku PET Centre, Turku, FINLAND, [2]Institute of Evolutionary Physiology and Biochemistry, RAS, St. Petersburg, RUSSIAN FEDERATION, [3]Cardiac Imaging Division Alkmaar, Northwest Clinics, Department of Nuclear Medicine, Alkmaar, NETHERLANDS, [4]Nuclear Medicine Unit, DECBS, University of Florence, Florence, ITALY, [5]Cedars-Sinai Medical Center, Los Angeles, CA, UNITED STATES OF AMERICA, [6]University of Washington, Seattle, WA, UNITED STATES OF AMERICA, [7]Research Center of Applied and Preventive Cardiovascular Medicine, Turku, FINLAND.

Aim: ^{13}N-ammonia is widely used in myocardial perfusion quantification (MPQ) with PET. Several software packages (SWPs) enable it, and although there were cross-comparison studies for some of them, no one aimed at an exhaustive study including all packages available. Such a study was our aim. **Materials**

and Methods: At the moment of the abstract submission, five SWPs—Carimas, PMOD, QPET, Syngo.MBF, and UW-QPP—were compared using 57 clinical rest- and stress-PET myocardial perfusion scans (Siemens Biograph-16 TruePoint PET/CT). Briefly, 300 and 400 MBq of ^{13}N-ammonia were injected at rest and during adenosine (140µg/kg/min) stress. Each participating center performed MPQ (using all implemented tracer-kinetic models) blinded to the results of other SWPs. Myocardial flow reserve (MFR) was obtained as the ratio of stress to rest myocardial blood flow (MBF). Analysis was performed globally and regionally (LAD, LCx and RCA). The cross-comparison of the resulting estimates was conducted applying custom linear mixed model for repeated measures to produce two agreement metrics—intraclass correlation coefficient (ICC) and absolute difference between SWPs—calculated pairwise. Differences below 20% of median values with corresponding ICCs above 0.75 witnessed to good agreement. **Results:** Global MFR as estimated by 1TCM (DeGrado et al., 1996) in Carimas and PMOD was 2.44±0.14 and 2.99±0.14 correspondingly, with a difference of 20.6% (ICC=0.92). The most pronounced regional difference was 21.4%—in the LAD territory (ICC=0.90); the least - in RCA (14.4%, ICC=0.91). Global MFR as estimated by 2TCM (Choi et al., 1993) in PMOD and QPET was 2.95±0.14 and 2.69±0.14 correspondingly, with a difference of 9.6% (ICC=0.79). The most pronounced regional difference was 24.5%—in the RCA territory (ICC=0.51); the least - in LAD (1.1%, ICC=0.81). Finally, global MFR estimated by 2TCM (Hutchins et al., 1990) was 2.57±0.14 in Carimas, 2.33±0.14 in UW-QPP and 2.87±0.14 in Syngo.MBF; the largest difference was found between Syngo.MBF and UW-QPP (20.6%, ICC=0.84); the smallest—between Carimas and UW-QPP (9.2%, ICC=0.77). The most pronounced regional difference was 23.8% (ICC=0.46) between PMOD and UW-QPP in the RCA, while the smallest (3.0%) was found between Carimas and SYNGO in the RCA territory (ICC=0.64). **Conclusions:** There is moderate to good agreement in MPQ with ^{13}N-ammonia PET between available SWPs on global and regional levels.

OP-506

Assessment of the functional significance of coronary artery stenoses in patients with CAD using dynamic stress PET / CT with 13N-ammonium with the use of absolute values of myocardial blood flow and coronary flow reserve

I. V. Shurupova, I. P. Aslanidis, M. G. Shavman, E. P. Derevyanko, E. P. Derevyanko, I. V. Ekaeva; Bakoulev Scientific Center for Cardiovascular Surgery, Moscow, Moscow, RUSSIAN FEDERATION.

Purpose: To assess the possible contribution of the use of absolute values of myocardial blood flow (MBF) and coronary flow reserve (CFR) in the functional evaluation of coronary stenoses in patients with CAD. To compare CFR in patients with different degrees of coronary artery (CA) stenoses and ischemia severity according to semiquantitative perfusion stress PET/CT with 13N-ammonium. **Method:** 46 patients with CAD (mean age 64.7 ± 8.6 years) who underwent perfusion stress-PET/CT were examined on Biograph-64 (Siemens) in a dynamic mode. This allowed, in addition to the standard perfusion parameters (SSS

and SRS), severity of ischemia (SDS), to determine the MBF and the CFR value. Exclusion criteria were the presence of large scar in LV myocardium according to ECHO data or perfusion PET / CT, and the history of CA bypass grafting. **Results:** When comparing two groups with CA stenosis according to x-ray endovascular coronary angiography ≥75% (n = 27) and <75% (n = 19), the number of people with reduced CFR (<2.0) in the first group was 88.9%, in the second - 21.0%, the number of segments with a decreased CFR 34.8% and 5.9% respectively. There was a significant difference (p <0.001) of CFR value in the territory of CA with the most severe stenos between groups: 1.89 [1.53; 2.26] and 2.83 [2.33; 3.39], respectively. When comparing three groups: with no perfusion abnormalities (SSS ≤ 3, n = 7), insignificant (SSS = 3-8 points, n = 17) and moderate / severe disorders (SSS≥9, n = 22), CFR was significantly lower (p <0.01) in the third group (1.81 [1.39, 2.21]) compared with the first group (2.33 [2.06, 2.9]) and second group (2.83 [2.46, 3.59]). Significant differences were also found when comparing three groups with insignificant ischemia (SDS≤4, n = 15), moderate (SDS = 5-8, n = 12) and pronounced (SDS≥9, n = 19) (p <0.001) - CFR was lower in the third group (1.66 [1.27, 2.04]) compared with the first group (2.73 [2.25, 3.54]) and the second (2.67 [2.16, 2 , 97]). **Conclusion**: The value of the coronary reserve is significantly lower in patients with significant stenoses of the coronary arteries compared with the group of patients with small and borderline stenoses.Coronary reserve, calculated on the basis of absolute values of myocardial blood flow, confirms the significant differences between the group of patients with severe ischemia and patients with moderate and minor ischemia.

OP-507

Prognostic value of quantitative absolute myocardial stress perfusion in patients with chest pain and normal coronary arteries: A Nitrogen-13 Ammonia PET study

A. G. Monroy-Gonzalez[1], R. A. Tio[1], E. Alexanderson-Rosas[2], R. H. J. A. Slart[1]; [1]University Medical Center Groningen, Groingen, NETHERLANDS, [2]Department of Physiology, National Autonomous University of Mexico, MEXICO.

Introduction: Cardiac Syndrome X (CSX) has been referred as chest pain, normal coronary arteries and positive exercise stress test. Previous studies suggest that quantitative myocardial perfusion measurements can be reduced in patients with suspected CSX, independently of exercise stress test findings. Currently, the prognostic value of quantification of absolute myocardial perfusion with PET in patients with suspected CSX is unknown. **Aim:** We evaluated if abnormal absolute myocardial stress perfusion quantification with Nitrogen-13 Ammonia PET is related to higher incidence of mayor adverse cardiac events (MACE) in patients with normal or near normal coronary arteries. Methods: We retrospectively included 100 patients who underwent Nitrogen-13 Ammonia PET for quantification of global myocardial blood flow (MBF) during stress with adenosine. Normal MBF during stress was defined as ≥1.85 mL/g/min. Patients with significant coronary artery disease (>50% stenosis) demonstrated by invasive coronary angiography were excluded. MACE were

assessed as cardiac death, myocardial infarction (MI), and heart failure using the Kaplan-Meier method. **Results:** In our population 68% were female patients, mean age was 52±11 years old, 7% were diabetic, 37% had hypertension, and 20% were current smokers. Abnormal MBF during stress was found in 44% of patients. During follow up (8.9 ± 6.3 years) 6 patients presented at least one MACE. 5 patients who presented at least one MACE showed abnormal MBF during stress. Kaplan-Meier analysis showed that patients with abnormal MBF during stress had a significantly higher rate of MACE compared with those with normal MBF during stress (p= 0.02). **Conclusion:** Absolute myocardial stress perfusion quantification with Nitrogen-13 Ammonia PET predicts MI in patients with chest pain and normal or near normal coronary arteries. Further studies are needed in order to completely understand the role of MBF during stress in the prognosis of this group of patients.

OP-508

Feasibility of layer myocardial blood flow

R. Calabretta[1], *E. Milan*[2], *R. Giubbini*[3], *R. Durmo*[3], *L. Gallo*[2], *T. Kubik*[4,5], *R. Sciagra*[1]; [1]*Nuclear Medicine, DECBS, University of Florence, FLORENCE, ITALY,* [2]*Nuclear Medicine, San Giacomo Hospital, ULSS 2, Castelfranco Veneto, ITALY,* [3]*Chair of Nuclear Medicine, University of Brescia, Brescia, ITALY,* [4]*Pmod Technologies LLC, Zurich, SWITZERLAND,* [5]*Institute of Metrology and Biomedical Engineering, Warsaw University of Technology, Warsaw, POLAND.*

Previous studies suggest that myocardial blood flow (MBF) can be measured separately in the myocardial layers (subendocardium - Endo - and subepicardium - Epi) using ^{15}O-water PET. More recently, the feasibility of separate layer measurements with parametric mapping of $^{13}NH_3$ PET was demonstrated in patients with hypertrophic cardiomyopathy. Aim of the present study was to test the reliability of this method in patients with normal left ventricular (LV) wall thickness. The Dicom files of 48 patients submitted to rest and dipyridamole $^{13}NH_3$ PET for suspect or known coronary artery disease (CAD) and in whom invasive coronary angiography (ICA) was available were selected from the databases of our Institutions and anonymized. They were processed with dedicated software (PCARDP, Pmod Technologies) that calculated rest and stress MBF and coronary flow reserve (CRF) both for the entire LV wall (average) and for Endo and Epi separately. Starting from the 17 segments of the AHA model, the volume-weighted means for the three coronary artery territories and the whole LV were obtained, and then compared with ICA results. ICA identified 28 patients with significant CAD (showing > 75% stenosis in 25 territories, 100% occlusion in 10). According to ROC analysis, average CFR was the most effective for identifying CAD (area under the curve - AUC = 0.77, p < 0.003), followed by Endo CFR (AUC = 0.74, p < 0.005), stress average MBF (AUC = 0.73, p < 0.01) and stress Endo MBF (AUC = 0.73, p < 0.01). There were no differences in resting Endo and Epi MBF between normal and CAD territories, whilst they were highly significant under stress. On a territory basis, the best diagnostic performance was reached by stress Epi MBF and stress average MBF (both AUC = 0.76, p < 0.0001), followed by stress Endo MBF (AUC = 0.73, p < 0.0001). Interestingly, stress Endo MBF was the sole parameter that differentiated between segments subtended by > 75% stenosis versus 100% occlusion: (1.3 ± 0.4 vs. 1.1 ± 0.6 mL/min/g, p < 0.03). In conclusion, this study indicates that parametric $^{13}NH_3$ analysis allows the separate assessment of MBF and CFR in the myocardial layers with results that appear reasonable and compare well with the standard approach considering the entire myocardial wall. Although no specific advantage of the layer estimates could be demonstrated, the possibility that Endo MBF is more sensitive for discriminating different grades of stenosis severity deserves further attention.

OP-509

Effect of motion-induced PET-CT misalignment on cardiac function and myocardial blood flow measured using dynamic ^{15}O-water PET

M. Lubberink[1], *M. Ebrahimi*[1], *H. J. Harms*[2,3,4], *L. Poulsen Tolbod*[2], *J. Sörensen*[1,2]; [1]*Uppsala University, Uppsala, SWEDEN,* [2]*Århus University, Århus, DENMARK,* [3]*Brigham and Women's Hospital, Boston, MA, UNITED STATES OF AMERICA,* [4]*VU University Medical Centre, Amsterdam, NETHERLANDS.*

Aim: Motion-induced PET-CT misalignment artifacts are common in myocardial blood flow (MBF) measurements with ^{82}Rb and ^{13}N-ammonia. For ^{15}O-water, MBF is based on the clearance rate rather than uptake of the tracer. The clearance rate is determined by the shape of the time-activity curve, not its amplitude, and is thus not affected by attenuation correction errors. Hence, misalignment is hypothesized not to affect ^{15}O-water-based MBF to any large extent, but it may affect cardiac function measures derived from ^{15}O-water scans. The aim of the present work was to assess the effect of PET-CT misalignment on MBF, transmural MBF (MBFt), perfusable tissue fraction (PTF), cardiac output (CO), stroke volume (SV) and left-ventricular ejection fraction (LVEF) based on dynamic ^{15}O-water scans. **Methods**: 10 patients underwent 6 min PET scans after injection of 400 MBq ^{15}O-water at rest and during adenosine-induced stress on a Discovery MI PET-CT scanner. Attenuation correction was based on a respiration-averaged CT scan. Images were reconstructed using TF-OS-EM including PSF-recovery. PET-CT misalignment was induced by translation of the PET relative to the CT (1 cm caudal or cranial, 1 cm cranial + ventral, and 2.5 cm cranial + 1 cm ventral). MBF, MBFt, PTF, CO, SV and LVEF were calculated semi-automatically using aQuant software and values with and without misalignment were compared using correlation and Bland-Altman analysis. The original data, without misalignment, was analysed twice to assess intra-observer variability. **Results:** Intra-observer reproducibility was high, with $R^2 \geq 0.98$ for all parameters except LVEF during stress (R^2 0.80). CO and SV were not significantly affected by misalignment, with correlation between aligned and misaligned values >0.95 (CO) and >0.93 (SV) and no significant bias for all motions. For MBF, correlation was always >0.95 for all coronary flow territories and motions, and no significant bias was seen. For MBFt however, correlations were always lower, reducing to 0.89 in LCX for the largest misalignment at stress. LVEF

was only affected significantly for the largest misalignment. Correlation of misaligned PTF and original PTF values was lower, but no significant motion-induced bias was seen. **Conclusion**: With the exception of PTF and LVEF for >1.5 cm misaligment, misaligment-induced changes were generally similar to or slightly higher than intra-observer variability. PET-CT misalignment does not significantly affect MBF and cardiac function measures based on ^{15}O-water scans for misalignment up to 1.5 cm.

OP-510

Automatic extraction of left ventricular mass and volumes using parametric images from non-ECG-gated 15O-water PET/CT

J. Nordström[1,2], H. J. Harms[3], M. Lubberink[1,4], L. Tolbod[3], J. van den Berg[1], T. Baron[5], F. A. Flachskampf[5], T. Kero[1,6], J. Sörensen[1,6]; [1]Nuclear medicin & PET, Department of Surgical Sciences, Uppsala University, Uppsala, SWEDEN, [2]Centre for Research and Development, Uppsala University / Gävleborg County, Gävle, SWEDEN, [3]Department of Nuclear Medicine & PET Centre, Aarhus University Hospital, Aarhus, DENMARK, [4]Medical Physics, Uppsala University Hospital, Uppsala, SWEDEN, [5]Cardiology, Department of Medical Sciences, Uppsala University, Uppsala, SWEDEN, [6]Medical Imaging Centre, Uppsala University Hospital, Uppsala, SWEDEN.

Introduction: ^{15}O-water positron emission tomography (PET) is considered the gold standard for non-invasive quantification of myocardial blood flow (MBF). It has been shown to identify patients with significant coronary artery disease (CAD) with high accuracy. Hypertrophy with or without dilatation of the myocardium together with a reduction in stroke volume are common in nearly any advanced cardiac disease. Thus, in addition to MBF, assessment of left-ventricular (LV) volumes and mass provides important diagnostic and prognostic information and are vital in the clinical setting. Therefore, the aim of the present study was to investigate the feasibility of measuring LV geometry using dynamic ^{15}O-water PET/CT without ECG-gating. **Methods**: Parametric images of MBF, perfusable tissue fraction (PTF) and LV blood pool were generated automatically using kinetic modelling. Segmentation of the LV wall using PTF images generated regional MBF and PTF, and total ROI volume which was converted to LV mass (mLV). Segmentation of blood pool images generated LV end-diastolic (EDV) and end-systolic (ESV) volumes. Segmentation thresholds were studied analytically in a subset of patients. The generated values were combined to measure stroke volume (SV=EDV-ESV) and ejection fraction (EF=SV/EDV). Accuracy was determined by comparing PET to cardiac magnetic resonance (CMR) in 30 asymptomatic patients with high grade LV regurgitation (group A). Precision was determined as inter-observer variation in group A and by a test-retest PET study in 15 patients with suspected ischemic heart disease at rest (group B). Normal values were defined in nine healthy volunteers. **Results:** The accuracy of PET was good with correlations of r= 0.83, 0.88, 0.86 and 0.76 for m_{LV}, EDV, ESV and SV, respectively, compared to CMR (P<0.001 for all). EF was in the normal range (53%-75%) and had a weaker correlation of r=0.51 (P=0.004). m_{LV} was overestimated by 18%±13% com-

pared to CMR and the residuals were closely related to the eccentric remodelling (mLV/EDV) defined by CMR. EDV, ESV and SV were underestimated by 10%±10%, 19%±13%, 3%±15%, respectively, compared to CMR. EF was overestimated by 4%±5% compared to CMR. Inter-observer correlation and test-retest repeatability were excellent (r>0.97). Normal values from PET were in line with normal values from a local CMR cohort. **Conclusion**: Microvascular function and LV geometry can be measured automatically with high accuracy and precision from a single non-gated ^{15}O-water PET. The accuracy of m_{LV} from PET is affected by LV eccentricity.

Do.MoRe: Detector Technology

OP-511

A Promising PET Detector Design that Achieves 100 ps FWHM Coincidence Time Resolution

J. W. Cates, C. S. Levin; Stanford University, Stanford, CA, UNITED STATES OF AMERICA.

The past two decades have seen much improvement in coincidence timing resolution (CTR) for time-of-flight (TOF) positron emission tomography (PET). State-of-the-art clinical TOF-PET systems now achieve sub-400 ps FWHM (full-width-at-half-maximum) CTR, enabling benefits such as decreased patient radiation dose, shorter scan time, improved lesion detection and quantification, and less sensitivity to errors in data correction techniques (normalization, scatter, and attenuation). An important and long-standing milestone for clinical TOF-PET is 100 ps FWHM CTR. At that level of timing performance, more than a factor of five enhancement in reconstructed image signal-to-noise ratio is possible compared to non-TOF-PET, with the potential for a transformational impact in count starved and contrast limited imaging tasks. With advancements in silicon photomultiplier technologies, novel scintillation materials, and signal processing techniques, sub-100 ps CTR has been reported for relatively short and narrow individual scintillation crystal elements (e.g. 2x2x3 mm³). However, clinical PET requires arrays of tightly packed scintillation crystal elements with dimensions of at least 3x3x20 mm³ for high 511 keV photon detection efficiency. This increased crystal length reduces the light collection efficiency and increases the scintillation photon transit time variance, which degrade CTR. Our group has previously shown that coupling the photosensors to the long sides of the crystal elements instead of their small ends yields near-complete light collection efficiency, and reduced scintillation photon transit time jitter. In this configuration, a CTR of 102±1 ps FWHM is achievable with 3x3x20 mm³ LGSO:Ce scintillators, with the 3x20 mm² face coupled to a 6-element row of 3x3 mm² SiPMs, using simple leading edge time pickoff and a single timing channel. This is in contrast to a CTR of 137±2 ps FWHM that is achieved when the same crystals are coupled end-on to a single 3x3 mm² SiPM. Moreover, this "side

readout" configuration enables 3D position sensitivity (3DPS), which can be employed to extract more information from inter-crystal scatter events (the most likely event type), including (1) more accurate positioning of the first interaction and (2) an estimate of the incoming annihilation photon incident angle. The latter feature offers the potential to retain a high fraction of photon events that are normally rejected. These innovations can be packaged into a practical clinical detector module with mixed analog-digital multiplexing schemes that require a low number of readout channels. We present the design and proof-of-concept measurements for this advanced 100 ps FWHM CTR TOF-3DPS clinical PET scintillation detector module.

OP-512

First human images from a next generation SiPM based PET/CT system with improved time and spatial resolution

M. Casey[1], Z. Burbar[1], H. Rothfuss[1], V. Panin[1], D. Bharkhada[1], W. Howe[1], Y. Bradley[2]; [1]Siemens Medical Solutions, Knoxville, TN, UNITED STATES OF AMERICA, [2]University of Tennessee Graduate School of Medicine, Knoxville, TN, UNITED STATES OF AMERICA.

Purpose: PET/CT provides clinicians information on tumors that can be used for diagnosis, staging, and management of cancer. Silicon photomultipliers (SiPMs) offer a unique opportunity to design a PET detector with smaller crystals and better time resolution thus potentially improving the quality of the clinical findings. This paper will present both phantom measurements and patient images from a new SiPM based PET/CT prototype that incorporates these features. **Materials and Methods:** The PET/CT uses a "Block" detector based approach with a 5x5 array of 3.2x3.2 LSO crystals coupled to a 1.6 cm x 1.6 cm array of 16 SiPMs. The ratio of the SiPM array area to scintillator is 100%. 128 of these "Blocks" are incorporated into a module. 19 of the modules are used to form an 82 cm diameter detector ring. The axial dimension of the ring is 26.3 cm. The spatial resolution and sensitivity of the system was assessed according to NEMA NU 2-2012 using [18]F. Time resolution was measured with the NEMA scatter phantom as proposed by Wang (IEEE TNS 2016). To further test the system, six human subjects (3 female, 3 male) were injected with 10.4 ±0.3 mCi of FDG at the University of Tennessee Medical Center under IRB approval. The subjects were first imaged on the Siemens Biograph mCT after 66 ±3.4 minutes then reimaged on the SiPM prototype at 131 ±16 minutes. Imaging time on the mCT was 1.5 minute beds, while 3 minutes per bed was used for the prototype. **Results:** FWHM measured at 1 cm was 3.23 mm radially, 3.27 mm tangentially and 3.84 mm axially using iterative reconstruction. Time resolution was 249 picoseconds (ps) in the gantry center with 2 mCi in the phantom and 265 ps with 30 mCi. Sensitivity was measured at 15.3 cps/kBq. Detector energy resolution measured in the system is approximately 10%. Lesions in all patient images from the prototype exhibited better defined margins and improved contrast compared to the mCT images. Brain images are more clearly defined. Liver images show improved homogeneity. **Conclusions:** The large area of the SiPM array provides superior time resolution, resulting in lower image noise. The measured

spatial resolution due to the 3.2 mm crystal is much improved compared with currently available commercial whole body systems. These improvements are exhibited in both phantom and patient imaging.

OP-513

Ultra-high Definition Isotropic 1mm Voxel Reconstruction in Clinical Wholebody PET - Is Digital PET Making It a Reality?

M. V. Knopp[1], J. Zhang[1], K. Binzel[1], M. I. Knopp[1], R. Moore[1], M. Friel[1], F. Giesel[2], C. L. Wright[1]; [1]The Ohio State University, Columbus, OH, UNITED STATES OF AMERICA, [2]University Hospitals Heidelberg, Heidelberg, GERMANY.

Purpose: Current PET imaging predominantly uses voxel sizes of 3-4 mm length or matrix sizes of less than 200^2. Compared to CT and MRI, this is substantially lower. With the introduction of next-generation solid state digital detection systems and greatly improved time of flight resolution, we initially explored, demonstrated and now clinically assess the feasibility and performance characteristics of $1 \times 1 \times 1$ mm[3] image reconstruction. **Subjects & Methods:** 43 patient studies from a clinical trial that performed oncologic whole body FDG PET/CT on a next generation digital photon counting system (Vereos, Philips, dPET) were included. Ultra-high definition (UHD) isotropic 1mm reconstructions were performed from list mode data for all studies and compared to current practice isotropic 4mm (SD) reconstructions. The reconstruction methodologies have been previously optimized and validated by phantom and other clinical data Two independent, highly experienced clinical readers blinded to all clinical history were asked to identify measurable and indeterminate lesions based on the SD whole body data sets. Several days after the initial task, the readers were asked to independently review the lesions identified by the other reviewer on the SD images and classify their level of diagnostic confidence on a -5 to +5 continuous scale. Again several days later using a randomized order, the readers reviewed the lesions on the UHD images. Another nonclinical reader reviewed which lesions matched between the readers. Inter- and intra-reader assessments were performed and kappa statistics will be calculated. Additionally the readers were asked to classify overall image quality, visual noise level and artifacts. **Results:** Image quality was rated acceptable or better for diagnostic reads in all 43 SD and UHD reconstructed studies. A total of 187 lesions were evaluated. The overall confidence rating was significantly (P<.01) higher for UHD reconstruction compared to SD. The difference in confidence was most pronounced for lesions smaller than 15 mm. In no case was the confidence reduced on the UHD images compared to SD. Additionally, the image quality was consistently ranked more preferable on UHD images compared to SD, independent of the reader. **Conclusion:** Ultra-high definition reconstruction was not only feasible in all cases, it consistently enabled a higher confidence for clinical diagnostic assessment. The difference is most pronounced in small metabolically active lesions. UHD appears to fully leverage the technological advances of digital PET and it is on the verge of becoming a clinical reality which needs to be further validated in larger clinical trials.

OP-514

Evaluation of Whole-Body and Small FOV CZT Gamma Cameras

J. W. Hugg, B. W. Harris, H. Tomita; Kromek / eV Products, Saxonburg, PA, UNITED STATES OF AMERICA.

Introduction and Purpose: Pixelated semiconductor direct-conversion CdZnTe (CZT) gamma photon detector arrays have been used in several molecular imaging applications, including small-animal and whole-body human SPECT, cardiac SPECT, and molecular breast imaging (MBI). The interplay of gamma camera and collimator geometric design, gantry motion, and image reconstruction determines image quality and dose-time-FOV trade-offs. Both dose and exam time can be minimized using CZT gamma cameras without compromising diagnostic content. **Materials and Methods:** We designed a modular gamma detector (4.4 cm square with 2 mm pixel pitch) and tiled it in two array sizes to evaluate CZT capabilities: a small FOV camera (8.8 cm square, 44 x 44 pixels) and a whole-body SPECT camera (39.6 cm x 52.8 cm, 198 x 264 pixels) that we mounted on a refurbished SPECT gantry for technology demonstration. We evaluated the performance of these gamma cameras using the NEMA NU1 standard. **Results:** Compared to NaI scintillator gamma cameras: intrinsic spatial resolution improved from 3.8 mm to 2.0 mm; energy resolution improved from 9.8% to < 4 % at 140 keV; non-detection camera edges are reduced about 3-fold. We measured intrinsic flood field uniformity of ±0.8% integral and ±0.4% differential, system spatial resolution at 10 cm with an LEHR collimator of 6.8 mm and 7.5 mm without and with scatter, and intrinsic detector count rate performance of 1.4 M cps at 20% loss and 6.1 M cps maximum observed. These metrics are significantly better than scintillator SPECT systems. We have designed and are building a pixel-registered square-hole collimator to optimize the resolution-efficiency tradeoff. **Discussion and Conclusions:** Excellent energy resolution enables better scatter rejection and improved image contrast, further enhanced by excellent uniformity; the optimal FOV is increased to the entire camera area. Smaller pixels improve partial-volume dilution and quantitation. Spatial resolution is improved, even with hexagonal-hole collimators, but registered square-hole collimators provide significantly better resolution and a boost of about 30% in sensitivity which can lower dose and/or exam time. The non-paralyzable CZT cameras count at much higher count rates, enabling new first-pass and pharmacokinetic studies. Advances in detectors, collimators, and image reconstruction have significantly improved efficiency of CZT-based molecular imaging systems and the cost of CZT detectors has steadily declined.

OP-515

First Experience with Fast Imaging Using Discovery MI PET/CT

*I. Sonni, S. Park, L. Baratto, N. Hatami, G. Davidzon, S. Srinivas, S. Gambhir, **A. H. Iagaru**; Stanford University, Stanford, CA, UNITED STATES OF AMERICA.*

Introduction: We recently installed the first of a new generation PET/CT systems that bring together silicon photomultiplier (SiPM) technology first used in the SIGNA PET/MRI, with time-of-flight (TOF) and Q.Clear reconstructions. In this study, we investigated the impact of various acquisition times on image quality using this SiPM-based PET/CT. **Methods:** We reviewed data from 58 participants who were scanned using the GE Discovery MI PET/CT scanner. The administered dosages ranged 6.1-11.6 mCi (mean±SD: 9.4±1.3) and imaging started at 71-137 minutes (mean±SD: 98±17) after administration of the radiopharmaceutical. The patients' BMI ranged 17.7-46.2 (mean±SD: 26.6±5.5). We retrospectively reconstructed the raw data at 30 sec/bed, 60 sec/bed, 90/sec bed, 120 sec/bed and at the standard image acquisition time per clinical protocol (3-5 minutes/bed depending on BMI). Each reconstruction was reviewed blindly and independently by 2 nuclear medicine physicians and scored using a Likert scale (1 - poor, 5 - excellent quality). **Results:** The scores for PET images were 2.6±0.6 for the 30 sec/bed reconstructions, 3.7±0.7 for the 60 sec/bed reconstructions, 4.5±0.7 for the 90 sec/bed reconstructions, 4.8±0.3 for the 120 sec/bed reconstructions and 4.9±0.3 for the standard reconstructions. The addition of a regularized reconstruction algorithm to images reconstructed at 120 sec/bed and standard reconstruction resulted in scores of 4.7±0.7 and 4.8±0.4, respectively. Inter-reader agreement on image quality assessment was good, with a weighted kappa of 0.80 (95% CI: 0.72 - 0.81). Almost half of each reader's ratings were 5 (Excellent Quality). There was a significant positive effect of time on ratings (OR=1.05, 95%CI: 1.04-1.06, p<0.001), and significant negative effects of BMI>30 (OR=0.05, 95%CI: 0.02-0.12, p<0.001). There was no significant effect of administered dosage (OR=1.35, 95%CI: 0.95-1.91, p=0.090). **Conclusion:** Our results suggest that despite significant delays from injection to imaging compared to standard clinical operations and even in a population with average BMI>25, images can be acquired as fast as 90 sec/bed using the SiPM PET/CT and still result in very good image quality (average score >4). Additionally, one can reduce the administered dosage and still scan fast (120 sec/bed) while maintaining very good image quality.

OP-516

Phase Ia Trial Comparing Higher Definition Digital Photon Counting PET/CT with Current Photomultiplier PET/CT for Head and Neck Oncology

C. L. Wright[1], A. D. Bhatt[1], K. Binzel[1], I. R. Washington[1], P. Bhatia[1], P. Subramanian[1], J. Zhang[1], P. Maniawski[2], M. V. Knopp[1]; [1]The Ohio State University, Columbus, OH, UNITED STATES OF AMERICA, [2]Philips Healthcare, Cleveland, OH, UNITED STATES OF AMERICA.

Purpose/Introduction: Conventional photomultiplier PET/CT (cPET/CT) imaging with FDG is used clinical for the routine detection of occult malignancy, staging and assessment of treatment response. A recent technology innovation has replaced the photomultiplier tubes in the PET gantry with solid-state digital photon counting PET detectors (dPET/CT). Digital PET technology enables higher definitionPET imaging

with smaller voxel volumes and reduced partial volume effects. Our aim is to assess qualitative and quantitative imaging characteristics of dPET/CT compared to cPET/CT in patients with head/neck cancer. **Subjects & Methods:** Digital PET/CT (Vereos, Philips) was used to evaluate 30 patients in an ongoing intra-individual comparison trial and compare its image characteristics to cPET/CT (Gemini, Philips). Routine cPET/CT was performed at ~75 min p.i. using 481 MBq FDG and investigational dPET/CT either at ~55 min or ~95 min p.i. PET data was acquired in list-mode with all other acquisition aspects kept identical. Conventional PET images were reconstructed using Time-of-Flight with voxel volumes 4x4x4 mm^3 (standard definition/SD) and dPET images were reconstructed using Time-of-Flight with different voxel volumes 4x4x4 mm^3, 2x2x2 mm^3 (high definition/HD), and 1x1x1 mm^3 (ultra-high definition/UHD). Image sets were evaluated for overall quality, lesion detection, diagnostic confidence and background quality by a blinded reader panel. **Results:** For all patients, cPET and dPET images were rated as evaluable. Higher definition dPET imaging produced substantially improved image quality for qualitative and quantitative assessment of the primary malignant as well as metastatic lesions with no appreciable effect on the background FDG activity. Although UHD dPET data sets were consistently rated best, both HD and UHD dPET data sets demonstrated improved lesion detectability with sharper delineation of small lesions (≤15mm) and better characterization of larger heterogeneous lesions (>15mm) when compared with SD cPET. Quantitative SUV assessment of larger lesions using higher definition dPET yielded comparable SUVmax values whereas smaller lesions demonstrated higher SUVmax values. **Discussion/Conclusion:** FDG PET imaging in head/neck oncology is widely used and contributes tremendous clinical value to staging and therapy response assessment. Higher definition dPET/CT demonstrates improved visual and quantitative assessment of head/neck cancer patients when compared with cPET. For dPET, its faster timing resolution (~325 ps) compared with cPET (~550 ps) and its higher definition reconstructions both contribute to decreased partial volume effects and more precisely localization of FDG activity within lesions. Continued optimization and development of higher definition PET technologies will further advance precision imaging and therapy planning approaches.

PET 20.0: a cost-efficient, 2mm spatial resolution Total Body PET with point sensitivity up to 22% and adaptive axial FOV of maximum 2.00m

S. Vandenberghe[1], E. Mikhalyova[2], B. Brans[3], M. Defrise[4], T. Lahoutte[4], K. Muylle[4], R. Van Holen[5], D. R. Schaart[6], J. S. Karp[7]; [1]MEDISIP-Ugent, Gent, BELGIUM, [2]Department of Biomedical Engineering, University of California Davis, Davis, CA, UNITED STATES OF AMERICA, [3]Department of nuclear medicine UZGent/Ugent, Gent, BELGIUM, [4]Dept of nuclear medicine, Free University of Brussels, Brussels, BELGIUM, [5]MEDISIP-Ugent-Molecubes, Gent, BELGIUM, [6]Radiation Science & Technology, Delft University of Technology, Delft, NETHERLANDS, [7]PET instrumentation Group, University of Pennsylvania, Philadelphia, PA, UNITED STATES OF AMERICA.

Aim: Total body PET (TB-PET) is a very promising concept for new applications in molecular imaging and biomedical research with the only drawback the high material costs for building the system. The aim of this study is the optimisation of the length, energy settings and configuration of a long axial TB-PET system based on 15 mm thick monolithic LYSO scintillator with SiPM readout and a transverse diameter of 63 cm. **Material and Methods:** The central point sensitivity and volume sensitivity (uniform cylinder of 20 cm transverse and 1 or 2m length) was evaluated for an axial length from 25 cm to 2m. The 1m long system was also configured for long objects (up to 2m) without increasing the cost by axially separating the 32 rings. Due to oblique data redundancy the full object can still be reconstructed (with adapted sensitivity correction) as shown already by several designs with axial gaps. Finally the effect of lowering the energy threshold on the sensitivity of the 1m long system was evaluated. **Results:** The point source sensitivity increase per additional axial ring is the largest in the range from 25-100 cm and reduces clearly for larger axial extents above 1m. For a 100 cm long water phantom the gain in total sensitivity by extending the scanner from 1m to a fully populated 2m is only 46 %. For the 2 m long phantom the gain in sensitivity is much higher: +137 %. The same 2m phantom in a 1.5 m long scanner with 33% missing rings and in a 2m long scanner with only 50 % populated rings gives respectively only 15 % and 26 % less counts than in a 1m long scanner. Lowering the energy threshold to 250 keV resulted in a point source sensitivity of 22 % for a 1 m scanner. **Conclusions:** As shown in other studies 70-100 cm seems an optimal length for maximizing the point and volume sensitivity in a realistic object (20-35 cm diameter). The cost of detectors can be reduced by 50 % by using a 1m long scanner. This system will be excellent for most of the applications. The system can be adapted by separating the rings in the axial direction for the special cases where larger axial (> 1m) FOV for eg. total body dynamic imaging is required. The loss in sensitivity can be compensated by increasing the typically short acquisition times for TB-PET.

OP-518

A New Direction to Explore to Advance Coincidence Time Resolution for Time-of-Flight Positron Emission Tomography

*L. Tao, **C. S. Levin**; Stanford University, Stanford, CA, UNITED STATES OF AMERICA.*

Introduction: We are exploring a new detection mechanism for 511keV photons that has the potential to achieve < 10ps coincidence time resolution (CTR). A limiting factor for achieving < 100ps CTR for time-of-flight positron emission tomography (ToF-PET) detectors is the intrinsic scintillation process. In order to overcome this limit, we studied the modulation of optical

properties that occurs in a crystal resulting from 511keV photon interactions, instead of scintillation, with the ultimate goal to achieve < 10ps CTR. **Materials and Methods:** The ionization charges created from 511keV photon interactions will induce fast modulations in a detector material's optical properties, which can be observed using methods of modern optics. Initial efforts used a 5×5×5mm^3 cadmium telluride (CdTe) crystal and a 5×5×5mm^3 bismuth silicon oxide (BSO) crystal. The refractive indices of both crystals are modulated as a result of a locally perturbed electric field caused by the production of ionization charges, known as *electro-optic modulation*. With a two-beam interference setup, an interference pattern is generated by one laser beam which traverses the detector crystal and another beam which does not. The refractive index modulation resulting from ionization charges was observed and quantified by monitoring the magnitude of spatial shifting of the interference pattern. We also experimented with optical cavities with the detector crystal inside. Light transmission of the cavity is very sensitive to changes in the refractive index of the detector crystal produced when ionization charges are created. For ionization sources, we employed various radionuclides as well as a laser diode. For both approaches, we also studied the influence of crystal bias voltage on the modulation signal. **Results:** With both radionuclide and laser diode as sources of ionization, sensitivity to ~10^{-6} refractive index change was observed with 1000V bias voltage and no optical cavity. The amplitude of this modulation signal is linearly dependent on the detected event rate as well as the average ionizing photon energy. We also saw that the amplitude of the modulation signal is linearly dependent on crystal bias due to charge multiplication effects, while optical amplification enabled via the optical cavity enhances the modulation signal by an additional 130-fold with 95% reflectivity cavity mirrors and a focused beam. **Conclusion:** We have shown proof of concept that the mechanism of optical property modulation can be used to detect and quantify ionizing radiation photons. Our future work focuses on achieving individual 511keV photon detection with < 10ps CTR.

An intrinsically radioactive metal-organic framework (MOF) nanomaterial for Cerenkov luminescence-triggered cancer phototherapy: focused on deep-tissue tumor

H. Hong, D. Chen, D. Yang, W. Lu; University of Michigan, Ann Arbor, MI, UNITED STATES OF AMERICA.

Purpose: As one of the cancer treatment option, the primary limitation for photodynamic therapy (PDT) is that laser used to irradiate photosensitizers can only penetrate less than 1 cm, thus PDT is more suitable for treating superficial and localized tumors. To enhance the applicability of PDT, our goal is to develop a nanoplatform with intrinsic light emission for PDT of deep-tissue tumors. Recently, we successfully incorporated ^{89}Zr into different types of metal-organic framework (MOF) nanomaterials with strong radiochemical stability. Cerenkov luminescence from ^{89}Zr can be used as an internal excitation for photosensitizer (porphyrin) inside MOF structure. In addition, the existence of ^{89}Zr enables the tracking of MOF *in vivo*. **Methods:** Porphyrin and ^{89}Zr-containing PCN-224 type MOF nanomaterial was synthesized by a hydrothermal method with tetra-kis(4-carboxyphenyl)porphyrin as the bridging ligand for Zr_6 clusters. A pyrene-derived polyethylene glycol (Py-PGA-PEG) was used to increase the dispersity of ^{89}Zr-PCN-224 and provide reaction sites for attachment of a tumor-targeting ligand (F3, against nucleolin). Fluorescence from PCN-224 can be used as a visualizer in flow cytometry and confocal fluorescence microscopy to investigate the interaction between PCN-224 and different cells. Size and physical property characterization was conducted

before *in vivo* investigation by PET imaging and biodistribution studies. The treatment efficacy of ^{89}Zr-PCN-224 was evaluated at both cellular level and *in vivo*. Toxicity evaluation of PCN-224 conjugates was also done. **Results:** PCN-224 had a size range of 40-80 nm based on TEM measurement. ^{89}Zr could be efficiently incorporated into PCN-224 structure with a specific activity up to 2.4 GBq/mg, with good radiochemical stability. PCN-224/Py-PGA-PEG-F3 had strong internalization into MDA-MB-231 cells but showed minimal interaction with L929 cells. More potent and fast accumulation of ^{89}Zr-PCN-224/Py-PGA-PEG-F3 into MDA-MB-231 tumors was observed (9.3 ± 2.4 %ID/g at 0.5 h, n = 4) compared with ^{89}Zr-PCN-224/Py-PGA-PEG (3.4 ± 2.4 %ID/g at 0.5 h, n = 4), and histological analysis substantiated the specificity of ^{89}Zr-PCN-224/Py-PGA-PEG-F3 against nucleolin-positive tumors. We confirmed that ^{89}Zr could excite the fluorescence from PCN-224 and initiate the production of ROS, which caused significant toxicity against cancer cells. PCN-224/Py-PGA-PEG did not pose acute or chronic toxicity to the test subjects at 10 mg/kg. Finally, injection of radioactive PCN-224 conjugates showed interference to the growth of deep-tissue tumors. **Conclusion:** We successfully synthesized radioactive PCN-224 MOF nanomaterial in this report. This nanoplatform can achieve triple functions: tumor detection (by PET), deep tumor treatment, and therapeutic cargo delivery (in the future).

OP-533

Formulation and in vivo biodistribution of 57Co-porphyrin-labelled hydrophobic liquid nanoparticles

P. Hervella[1], J. Dam[2], H. Thisgaard[2], C. Baun[2], B. B. Olsen[2], P. Høilund-Carlsen[2], D. Needham[1]; [1]Center for Single Particle Science and Engineering, Odense, DENMARK, [2]Odense University Hospital, Odense, DENMARK.

Introduction: In personalized nanomedicine, identification of patients most likely to respond to a nanomedicine treatment, can be identified by PET imaging. We aimed to develop a radiolabelled nanoparticle of the same size and structure as the subsequent therapeutic nanomedicines but labelled with a long-lived PET radionuclide. ^{55}Co is a PET imaging isotope for long-circulating molecules and macromolecules due to its half-life of 17.5 h and average energy of 570 keV. ^{57}Co ($t_{1/2}$ 271.6 days) is a SPECT isotope useful for preclinical studies of biodistribution and pharmacokinetics of nanoparticles. Because these ions are isoluble in a hydrophobic material, we used the hydrophobic porphyrin octaethyl porphyrin (OEP) in combination with two hydrophobic axial ligands (oleylamine, OA) to chelate cobalt to encapsulate the radionuclide inside hydrophobic liquid nanoparticles (LNP). **Methods:** LNPs were prepared by the fast ethanol injection method and were composed of a liquid core (Triolein) surrounded by a lipid monolayer (DSPC:Cholesterol:DSPEPEG). The LNPs were labelled with ^{57}Co using OEP and OA as chelators. A biodistribution study was carried out in male NOD-SCID mice inoculated subcutaneously in the right flank with 10^6 AR42J pancreatic cancer cells. **Results:** The size of LNPs loaded with a cobalt complex was 40 ± 5 nm, and the loading capacity of OEP-Co-OA in LNP was 5 mol%. In absence of the axial OA

ligands, the leakage of free [57]Co after 24 h incubation was 62%, which was significantly higher than the free [57]Co leakage from OEP-[57]Co-OA loaded LNP (only 12 %). The results demonstrate the positive effect of the additional OA ligands on the stability of the OEP-[57]Co complex. Finally, the biodistribution study showed that the concentration of LNP particles in the blood was 30% ID/g 1 h after injection with an estimated half-life of about 7.2 h. Remarkably, the accumulation of LNP in the tumor was as high as 9.5 % ID/g 24 h after injection. The most important result was that the nanoparticles could indeed accumulate in AR42J tumors up to levels that are greater than other nanoparticles like liposomes and at about half the values reported for the molecular agent [57]Co-DOTATATE. **Conclusion:** The Co[2+] ion can be encapsulated and retained inside LNPs when the ion is chelated by the hydrophobic chelator OEP in combination with 2 OA. The method described here for labelling of LNPs with cobalt is, therefore, now ready for labelling of nanomedicines with [55]Co for preclinical *in vivo* PET-imaging.

OP-534

Pretargeted tumor imaging with a polymer: Reducing absorbed radiation dose and increasing imaging contrast

E. J. L. Stéen[1], K. Nørregaard[2], A. Birke[3], P. E. Edem[2,1], J. T. Jørgensen[2], R. Rossin[4], M. Robillard[4], A. Kjaer[2], M. Barz[3], M. M. Herth[1,2]; [1]University of Copenhagen, Copenhagen, DENMARK, [2]Rigshospitalet, University Hospital, Copenhagen, DENMARK, [3]Johannes-Gutenberg University, Mainz, GERMANY, [4]Tagworks Pharmaceuticals BV, Eindhoven, NETHERLANDS.

Introduction: Nanomedicines have demonstrated potential as targeting-vectors for diagnosis and/or therapy of cancer. Due to the leaky vasculature and reduced lymphatic drainage in some types of tumors in comparison to healthy tissue, long-circulating nano-sized agents tend to accumulate in tumors. This phenomenon is called the enhanced permeability and retention (EPR) effect.[1] The EPR effect is a relevant approach for tumor targeting in pretargeted tumor imaging, where the targeting is separated from the actual imaging step. A pretargeted approach enables the use of short-lived radioisotopes, which reduces the radiation doses for the patients and increases imaging contrast. Herein, we describe a pretargeted imaging approach, where a *trans*-cyclooctene (TCO) functionalized polyglutamic acid-*graft*-polysarcosine copolymer (PGA-*graft*-PSar-TCO) was allowed to accumulate within the tumor via the EPR effect, before a [^{111}In]In-labeled DOTA-tetrazine (Tz) derivative[2] was administered intravenously (i.v.). The latter reacts with the TCO:s on the polymer in an inverse electron demand Diels-Alder (iEDDA) reaction, which allows imaging of the polymer accumulation in the tumor. **Subjects & Methods:** The PGA-*graft*-PSar-TCO was synthesized by ring-opening polymerization of *N*-glutamic acid (Ot-Bu) carboxyanhydride, deprotection, postpolymerization modification with PSar (<40%) and functionalized with TCO (16%). The [^{111}In]In-DOTA-Tz was prepared as reported in the literature in a radiochemical conversion (RCC) of ≥99%. Analysis was performed by radio-TLC. *In vivo* stability studies and pretargeted microSPECT/CT imaging was performed using the ^{111}In-labeled PGA-*graft*-

PSar, PGA-*graft*-PSar-TCO and [^{111}In]In-Tz-DOTA in BALB/c mice bearing subcutaneous colorectal mouse tumors (CT26). **Results:** The PGA-*graft*-PSar-TCO was labeled with [^{111}In]In-DOTA-Tz via the iEDDA reaction in phosphate buffer at room temperature for 5 min in a RCC of 82-85%. I.v. injection of ^{111}In-labeled PGA-*graft*-PSar resulted in tumor accumulation after 22 h. After establishing the stability and time for clearance of the polymer, the *in vivo* iEDDA reaction was tested by injecting PGA-*graft*-PSar-TCO i.v. 72 h before i.v. injection of the [^{111}In]In-DOTA-Tz. After 24 h a clear visualization of the tumor was observed. **Conclusion:** A new easily accessible PGA-*graft*-PSar copolymer functionalized with TCO for pretargeted tumor imaging based on the EPR effect and *in vivo* click chemistry has been developed. Its utility was validated with the previously reported [^{111}In]In-DOTA-Tz. Future work is to use this polymer in pretargeted tumor imaging in companion of Tz:s labeled with short-lived radioisotopes e.g. [11]C and [18]F. **References:** 1. Matsumura Y. *et al. Nanoparticle-based radiopharmaceuticals: is there a future to [45]TiO2 nanoparticles?

P. Costa[1], L. F. Metello[1,2], F. Alves[3], M. D. Naia[4]; [1]Nuclear Medicine Department, ESS|P.Porto, Porto, PORTUGAL, [2]IsoPor S.A., Porto, PORTUGAL, [3]Institute for Nuclear Sciences Applied to Health, University of Coimbra, Coimbra, PORTUGAL, [4]CEMUC® - Physics Department, ECT-UTAD, Vila Real, PORTUGAL.

Introduction: Nanoparticles are being studied as drug delivery systems, and its application as vectors for radionuclide-based molecular imaging is a powerful tool of growing interest. Recent data is suggesting that functionalized titanium dioxide nanoparticles (TiO$_2$) can be surface-engineered to target cancer cells. On other hand, there is a global interest on the study of unconventional radionuclides for PET imaging. Among several examples, [45]Ti could be presented as one of the most interesting options, with physical properties (half-life of 3.09h and positron maximum energy of 1040 keV) together with results of some preclinical applications already tested providing evidences demonstrating that this radionuclide could allow good image quality. **Aim:** It is aimed to explore the potential role of [45]Ti to radiolabel biologically compatible TiO$_2$ nanoparticles for biomedical imaging applications and to describe the most favorable strategies for radionuclide and radiopharmaceutical production. **Materials and Methods:** This work departs from the presentation of our recent findings regarding the production of [45]Ti in a low energy cyclotron (IBA® Cyclone 18/9), and will be complemented with the exploration of the nanoparticle synthesis processes and radiolabeling related issues, aiming to provide a proposal for the optimization of the entire process. **Results and Discussion:** Our experimental results show that [45]Sc(p,n)[45]Ti nuclear reaction seems to be feasible for the production of [45]Ti in low energy cyclotrons, with cross-section values presenting a peak for proton beam energies of 10-14 MeV, and a thick target yield of 433.64 MBq.μA[-1]sat. Solid targetry

study is being implemented in the way to develop a prototype of target to be widely used for [45]Ti production. In what regards to nanoparticle radiolabeling, different methodologies could be used, including activation methods and synthesis based on radioactive precursors. Apart from other advantages related with the specific activity obtained, synthesis based on radioactive precursors appears to be the most simple and favorable option in this context, mainly due to the coincidence between the nanoparticle chemical nature and the radionuclide aimed to be used for radiolabeling. **Conclusion:** According to all evidences already tested and conjugated with the theoretical and prospective vision here presented, radiolabeling of TiO_2 nanoparticles with [45]Ti could constitute a tool to provide *in vitro* biodistribution studies, allowing also the *in vivo* monitoring of its biological distribution and pharmacokinetics, while could act as a theranostic tool for cancer. A proposal of a production process for [45]TiO_2 nanoparticles will be presented.

OP-536

Radiollabeling and biodistribution studies in a rat model of lipid-based nanosystems designed for the treatment of wounds.

M. Collantes[1], G. Quincoces[2], R. Ramos-Membrive[2], M. Ecay[3,4], A. Aldave[3,4], M. Pastor[5], G. Gainza[5], E. Gainza[5], I. Peñuelas[1,2,4]; [1]Nuclear Medicine, Clínica Universidad de Navarra, Pamplona, SPAIN, [2]Radiopharmacy Unit, Clínica Universidad de Navarra, Pamplona, SPAIN, [3]MicroPET Unit, Clínica Universidad de Navarra, Pamplona, SPAIN, [4]Center for Applied Medical Research, Pamplona, SPAIN, [5]Biopraxis Research AIE, Vitoria, SPAIN.

Aim: Lipid nanoparticles (NPs) for the delivery of growth factors and antibiotics lead to improve the treatment of complex wounds, allowing a controlled release of active ingredients The aim of this work was to optimize the radiolabelling of lipid-NPs under development to determine their retention time in a rat wound healing model by biodistribution studies using molecular imaging technology. **Material and methods:** Lipid-NPs were prepared by hot melt homogenisation followed by high-pressure homogenisation step. Precirol ATO 5 and Miglyol 182 were selected as core lipid and Dextran 40 as cryopreservative[1]. Lipid-NPs were radiolabelled with ^{99m}Tc by direct reaction with SnCl2-reduced ^{99m}Tc-pertechnetate. A surgical wound was created in the back of female Wistar rats under anesthesia (n=17). After 24 hours, ^{99m}Tc-lipid-NPs (5mg/3MBq, n=9) or free ^{99m}Tc-pertechnetate (negative control, 6MBq, n=8) were administered inside the wound and covered with a dressing. *In vivo* biodistribution studies were performed by SPECT/CT 1, 2, 4, 8, 12 and 24 hours post-administration and quantified by drawing VOIs over CT images transferred to SPECT and calculating the percentage of activity in organs. At the end point, animals were euthanized and organs measured *ex vivo* in a gamma-counter for the calculation of the percentage of injected dose (% ID/organ). **Results**: Radiollabeling of lipid-NPs proceeded with high yield (> 95%, radio-TLC) and used without need for further purification. SPECT/CT images showed that almost all the radioactivity (> 98%) remained in the wound until 24 hours after

administration of ^{99m}Tc-lipid-NPs. Free ^{99m}Tc-pertechnetate was absorbed in control animals, with a wound retention of 7% at 24 hours and a gradual appearance in the stomach and intestine. *Ex vivo* study allowed a separate analysis of different parts of the wound, confirming *in vivo* data. In ^{99m}Tc-lipid-NPs animals, dressing retained a 41% ID, while 57% was found in the skin, 1% in subcutaneous tissue and 0.02% in the *panniculus carnosus* muscle. In free ^{99m}Tc-pertechnetate controls these %IDs were 6%, 13%, 0.2% and 0.01% respectively, while most of the activity was found in the stomach (20.5 %) and intestines (53.1 %). **Conclusions**: The radiolabeling of lipid-NPs was achieved in a simple, efficient and stable manner. *In vivo* biodistribution studies with SPECT/CT and *ex vivo* data confirmed an excellent lipid-NPs retention in the wound at least until 24h, recommending its use as treatment-delivery systems in complex wounds. OP-537

Chelator-free Radiolabeling of Iron Oxide Nanoparticles with [68]Ga For Dual-Modality PET/MR Imaging

*M. Karageorgou[1], J. Gallo[2], **C. Tsoukalas**[1], S. Xanthopoulos[1], M. Paravatou-Petsotas[1], D. Stamopoulos[3,4], M. Bañobre-López[2], P. Bouziotis[1]; [1]INRASTES, NCSR 'DEMOKRITOS', Athens, GREECE, [2]Advanced (magnetic) Theranostic Nanostructures Lab, INL, Braga, PORTUGAL, [3]Department of Solid State Physics, NKUA, Athens, GREECE, [4]Institute of Nanosciences and Nanotechnology, NCSR "Demokritos", Athens, GREECE.*

Aim: Dual-modality contrast agents, such as radiolabeled nanoparticles, are promising candidates for a number of diagnostic applications, since they combine the advantages of two different imaging modalities, namely SPECT or PET with MR imaging. This, in combination with hyperthermic capabilities of magnetic nanoparticles, can lead to highly-effective cancer theranostic agents. In this study, we describe the direct labeling of iron oxide nanoparticles (NPs), with the positron emitting radionuclide [68]Ga ($T_{1/2}$=67.8 min) and their subsequent *in vitro* and *in vivo* evaluation. Our goal is to evaluate the efficacy of the developed magnetic nanoparticles in passive tumor targeting. **Materials and Methods**: $Mn_xFe_{3-x}O_4@SiO_2$ nanoparticles were prepared through a two steps protocol. First, anisotropic manganese-doped magnetite nanoparticles with an average size of 13 nm were synthesized via thermal decomposition. In a second step, these particles were coated with a 20 nm silica shell. For the preparation of ^{68}Ga-labeled $Mn_xFe_{3-x}O_4@SiO_2$, the NPs were mixed with sodium acetate buffer pH 4 and 100 µL of ^{68}Ga eluate (~80 MBq, 30 min at 90°C). *In vitro* stability of ^{68}Ga-NPs was assessed in saline and serum. Radiolabeling and stability were assessed by TLC (ITLC-SG in citric acid solution, 0.1M). The *in vivo* behavior of the radiolabeled compound was evaluated in SCID mice bearing 4T1 breast cancer xenografts, at 30, 60 and 120 min post-injection of the radiotracer. **Results**: Successful labeling of the NPs was achieved with [68]Ga (purification via centrifugation, RCP ~ 98%), which was stable at RT up to 120 min post-preparation. ^{68}Ga-labeled $Mn_xFe_{3-x}O_4@SiO_2$

exhibited slow metabolic degradation in human serum (~85% at 120 min). Biodistribution studies in tumor-bearing SCID mice showed that $^{68}Ga-Mn_xFe_{3-x}O_4@SiO_2$ was mainly concentrated in the mononuclear phagocyte system (liver, spleen and lung). Moderate passive NP accumulation in tumor was observed (0.64 ± 0.19% ID/g at 120 min p.i.), with minimal uptake in other major organs. **Conclusion**: In this study we have proven the feasibility of labeling bare $Mn_xFe_{3-x}O_4@SiO_2$ magnetic nanoparticles with ^{68}Ga as a potential dual-modality imaging agent for diagnostic applications. This imaging radiotracer demonstrated high radio-labeling efficiency and high *in vivo* and *in vitro* stability, as well as moderate passive NP accumulation in 4T1 breast cancer tumors. These preliminary results prompt us to continue with the evaluation of the developed magnetic nanoparticles for passive tumor targeting, while functionalization of these nanoparticles with biomolecules (peptides, monoclonal antibodies) for active tumor targeting has been planned for the near future.

OP-538

Multifunctional Nanoprobes for Integrated PET / MR Imaging

S. Roux[1], *F. Bouraleh Hoch*[1], *V. Thakare*[2], *C. Bernhard*[2], *R. Bazzi*[1], *A. Oudot*[3], *B. Collin*[2,3], *F. Brunotte*[3], *F. Boschetti*[4], *F. Denat*[2]; *[1]Université de Bourgogne Franche-Comté, Besançon, FRANCE, [2]Université de Bourgogne Franche-Comté, Dijon, FRANCE, [3]Centre Georges-François Leclerc, Dijon, FRANCE, [4]CheMatech S.A.S., Dijon, FRANCE.*

Purpose: One important trend in molecular imaging is to combine several complementary techniques to exploit the advantages of each while overcoming their limitations. Among the numerous possibilities, the combination of magnetic resonance imaging (MRI) and positron emission tomography (PET) appears very attractive because it allies the high resolution and tissue contrast of MRI to the exceptional sensitivity of PET imaging. If the development of preclinical PET/MR scanners is in itself a significant challenge, the design of multimodal probes also constitutes an essential step for exploiting MRI/PET fused technology. **Subjects and Methods:** For achieving the development of multimodal probes for integrated MRI/PET, two strategies based on the multifunctional character of nanoparticles have been explored, keeping in mind that these nanostructured imaging agents must be removed by renal clearance. The first one consists in the synthesis of ultrasmall gold nanoparticles coated by two different types of chelator for a selective complexation of gadolinium ions (for MRI) and of positron emitters (for PET). The second strategy rests on the controlled assembly of maghemite nanoflowers detectable by MRI and of ultrasmall gold nanoparticles coated by chelators of positron emitters. Images of the biodistribution of these two kind of particles were obtained in rodents after labeling the nanoparticles with ^{64}Cu using a preclinical PET/MR scanner. **Results:** The reduction of gold salt in presence of a mixture of two different dithiolated chelators or in presence of dithiolated molecules containing two specific complexation sites provides ultrasmall gold nanoparticles (core size: 2-3 nm and hydrodynamic diameter: 6-8 nm) which are able to immobilize both gadolinium ions and 64-copper(II) ions. As a

result, the biodistribution of these nanoparticles can be monitored by T_1-weighted MRI and by PET on a same animal with the same imaging device integrating PET and MRI modalities after a single intravenous injection. The grafting of chelator coated gold nanoparticles onto superparamagnetic iron oxide nanoflowers using dopamine as linker yields also a nanoprobe (golden nanoflowers) for multimodal imaging (T_2-weighted MRI (superparamagnetic nanoflowers) and PET (radiolabeling by 64-copper). **Conclusion:** Each class of nanoparticles successfully behaves as imaging agent for integrated MRI/PET which are removed by body in large part by renal clearance. Since the ultrasmall gold nanoparticles and the golden nanoflowers are designed for remotely controlled therapy (radiosensitization with gold nanoparticles and magnetic hyperthermia with nanoflowers), the data collected by combining MRI and PET will be very precious for improving the therapeutic activity of these nanoparticles.

OP-539

Biodistribution of ^{99m}Tc-Phytate in a Sterile Inflammation Model in Mice

D. Priftakis[1], *M. Papachristou*[1], *S. Xanthopoulos*[2], *I. Datseris*[1], *P. Bouziotis*[2]; *[1]Evaggelismos Hospital, Athens, GREECE, [2]NCSR "Demokritos", Athens, GREECE.*

Purpose: When ^{99m}Tc-phytate is intravenously injected, particles in the nanometer range (150-250 nm) are formed, which are then taken up by phagocytic cells. This size can favor the radiotracer's extravasation in lesions with increased, newly formed or porous vasculature, such as inflammation and cancer, through the enhanced permeability and retention (EPR) effect. The aim of this work is the evaluation of the use of ^{99m}Tc-phytate to assess inflammation in mice. **Methods:** ^{99m}Tc-phytate was prepared by reconstitution of a commercial cold kit. The radiochemical purity was assessed by Thin-Layer Chromatography, using Whatman 1 paper and MeOH/H_2O (80/20 v/v) as the solvent system. The pH of the radiopharmaceutical was 6 and it was kept at room temperature before use. For the sterile inflammation model, 9 male Swiss albino mice were injected in the left thigh muscle with 100 μL of turpentine. The mice were then allowed to recover for 24 hours before being injected with 100 μL (3.7 MBq/100 μCi) of the radiotracer via the tail vein. A biodistribution study was performed at 1, 2 and 4 hours after the intravenous administration of ^{99m}Tc-phytate. 3 mice per time point were sacrificed by cardiectomy under slight ether anaesthesia and the main tissues and organs (blood, kidneys, liver, spleen, inflamed muscle, normal muscle etc.) were excised. Radiolabelled complex biodistribution over time was expressed as injected dose per gram (%ID/g). **Results:** The radiochemical purity of ^{99m}Tc-phytate was 98±0.5% as measured by thin layer chromatography. Biodistribution measurements reveal a higher uptake in the inflamed thigh at all time points (0.44±0.07%ID/g at 1 hour, 0.48±0.12%ID/g at 2 hours and 0.19±0.1%ID/g at 4 hours), when compared to uptake in the control tissue/non-inflamed thigh (0.14±0.08%ID/g at 1 hour, 0.2±0.14%ID/g at 2 hours and 0.13±0.07%ID/g at 4 hours), and the difference is sig-

nificant at 1 and 2 hours. The higher inflamed muscle/normal muscle ratio is 3.1 at 1 hour and showed gradual decrease over time. Moreover, there is a high uptake in the liver and spleen as expected. **Conclusions:** ^{99m}Tc-phytate has the ability to form particles of nanometer size when injected into the circulation, so it might be a non-toxic and low-cost nanoparticle-based SPECT imaging agent for the detection of inflammation. These promising preliminary results encourage us to follow the investigation with further experiments to clarify ^{99m}Tc-phytate's effectiveness in inflammation imaging and its potential use in tumor imaging.

Combination of baseline FDG-PET/CT total metabolic tumor volume and gene expression profil have a robust predictive value in patients with Diffuse Large B-Cell Lymphoma

M. N. Toledano[1], P. Desbordes[2], I. Gardin[1], P. Vera[1], F. Jardin[1], P. Ruminy[1], H. Tilly[1], S. Becker[1]; [1]Henri Becquerel Centre, Rouen, FRANCE, [2]QuantIF-LITIS, Rouen, FRANCE.

Purpose: To evaluate the predictive significance of Total Metabolic Tumor Volume (TMTV) measured on baseline FDG-PET/CT and confirm its added value to gene expression profile (GEP) with a new method of gene analysis RT-MLPA technology (Rapid Reverse Transcriptase - Multiplex Ligation - Dependent Probe Amplification Assay). **Subjects and Methods:** 114 patients with Diffuse Large B-Cell Lymphoma (DLBCL) were retrospectively included. Patients underwent FDG-PET/CT before R-CHOP or R-ACVBP regimen. TMTV was measured using 41% SUVmax thresholding method. They were classified in GCB or ABC subtypes according to the RT-MLPA method. Receiver operator characteristics (ROC) analysis was performed to determine optimal cut-off TMTV-value. Survival functions were estimated using a Kaplan-Meier method and were compared using a logrank test. Univariate and multivariate analysis were performed using a Cox proportional-hazards model. A logistic regression was also performed. P-value was corrected by Altman and Benjamini-Hoch-

berg models. **Results:** Patients had a median age of 66 years and the median follow-up was 40 months. 5 y-PFS was 54.4% and 5 y-OS was 62.3%. The optimal TMTV cut-off value was 261 cm³. Patients with a high TMTV (n=58) had a 5-year PFS and OS of 36.2% and 41.4% in comparison to 73.2% and 83.9% for patients with a low TMTV (n=56) (p=0.0038, HR=2.9 for PFS and p=0.0001, HR=4.33 for OS). ABC status was significantly associated to a worse prognosis. 5y-PFS were 55.8% *vs.* 62.9% (p=0.03, HR=1.77) and 5y-OS were 48.1% *vs.* 71% (p=0.03, HR=1.87) for ABC (n=52) and GCB (n=62) respectively. TMTV combined with molecular data identified 3 groups with very different outcome: i) patients with a low TMTV whatever the phenotype (n=56), ii) patients with a high TMTV and GCB phenotype (n=33), iii) patients with a high TMTV and ABC phenotype (n=25). These 3 groups had a 69.5%, 48.5%, 16% 5y-PFS (p<0.0001) and 83.9%, 57.6% 20% 5y-OS (p<0.0001), respectively. In multivariate analysis, TMTV, ABC/GCB phenotype and IPI score were independent prognostic factors for PFS (p=0.0454, p=0.0286 and p=0.0382, respectively) and OS (p=0.0223, p=0.0312 and p=0.0361, respectively). Logistic regression combining TMTV, ABC/GCB phenotype and IPI score was statistically meaningful between the two subgroups (p<0.0001) for PFS and OS (HR=4.47 and HR=5.53 respectively). **Discussion/Conclusion:** Combining TMTV and ABC/GCB phenotype at diagnosis individualized 3 risks categories of patients with significant different outcome. This integrative risk model could lead to a more accurate selection of patients, to increase tailor therapy.

OP-542

Improved Pulmonary Nodule Detection Using a Next Generation ^{18}F-FDG PET Imaging System

S. Park, L. Baratto, N. Hatami, G. Davidzon, S. Srinivas, V. Nair, A. Iagaru; Stanford University Medical Center, Stanford, CA, UNITED STATES OF AMERICA.

Introduction: One diagnostic indication for FDG PET is to determine whether a pulmonary nodule is benign or malignant based on the uptake of the nodule. However, FDG PET is limited by a relatively low spatial resolution (5 mm) that can lead to underestimation of tracer uptake and detectability in small lesions. The objective of this study was to evaluate the detection rate for pulmonary nodules using a next generation digital PET/CT system using Silicon Photomuliplier (SiPM) technology for increased contrast recovery and lower background variability in patients with known malignancies. **Subjects & Methods:** 76 consecutively enrolled patients who were referred for cancer staging by ^{18}F-FDG PET/CT underwent scans on the standard of care (SoC) and new digital system (Discovery Meaningful Insights) from September-December 2016. Images from the SoC PET/CT were reconstructed using time-of-flight (ToF) and ordered subset expectation maximization (OSEM) protocols. Images from digital PET/CT were reconstructed using ToF and a Bayesian penalized likelihood algorithm. Two experienced, nuclear medicine trained readers reviewed both scans for each patient in random order, blinded to clinical information and recorded the location and standardized uptake value (SUV) mea-

surement for each nodule. Differences in acquisition protocols were measured based on the distribution of the analyzed data and difference in detection rates assessed by McNemar's test. **Results:** Excluding one patient who had innumerable metastatic nodules on both scans, the number of lesions detected on the digital and standard of care PET/CT were 35 and 20, respectively. Of the 57 patients with negative standard of care scans, 7 (12%) demonstrated FDG-avid pulmonary nodules on the digital PET/CT. More lesions were detected on digital PET/CT in four patients who had nodules identified by both methods. Detection rates remained the same for 65/76 patients (86%), including 51 who were negative on both scans. Digital PET/CT nodules had a higher SUVmax compared to the standard of care (2.0; IQR 0.9-6.0 versus 1.3; 0.6-3.9, p < 0.001). **Conclusion:** Digital PET/CT system detects more FDG avid pulmonary nodules. FDG PET for diagnosing pulmonary nodules and staging metastatic disease to the lungs will require re-evaluation with this new, more sensitive platform.

OP-543

Treatment Reduction in Patients with Advanced-Stage Hodgkin Lymphoma and Negative Interim FDG-PET: Final Results of the International, Randomized, Phase 3 HD18 Trial by the German Hodgkin Study Group

C. Kobe[1], H. Goergen[2], M. Fuchs[2], H. T. Eich[3], C. Baues[4], V. Diehl[2], G. Kuhnert[1], A. Drzezga[1], M. Dietlein[1], A. Engert[2,5], P. Borchmann[2,5]; [1]Department of Nuclear Medicine, University Hospital of Cologne, Cologne, GERMANY, [2]German Hodgkin Study Group (GHSG), University Hospital of Cologne, Cologne, GERMANY, [3]Department of Radiation Oncology, University Hospital of Muenster, Muenster, GERMANY, [4]Department of Radiation Oncology, University Hospital of Cologne, Cologne, GERMANY, [5]Department of Internal Medicine I, University Hospital of Cologne, Cologne, GERMANY.

Background: In advanced-stage Hodgkin lymphoma (HL), recent clinical research indicates that metabolic response assessment early during therapy using FDG-PET (PET-2) might be suited to predict the individual outcome and eventually to adapt treatment intensity. **Aims:** We aimed to assess whether decreasing the number of eBEACOPP (dose-escalated bleomycin, etoposide, doxorubicin, cyclophosphamide, vincristine, procarbazine, and prednisone) cycles in patients with negative PET-2 is feasible without loss of efficacy as determined by progression-free survival (PFS). **Methods:** Between May 2008 and July 2014, we recruited patients with newly diagnosed advanced-stage HL aged 18-60 years. All patients received 2 cycles of eBEACOPP. PET-2 negative patients were randomly assigned to receive 6 or 2 additional cycles (i.e. 8x or 4x eBEACOPP in total, respectively). PET-positive residues after chemotherapy were irradiated. The trial was designed to exclude inferiority of 6 % or more of the group receiving only 4x eBEACOPP compared with the pooled groups receiving standard eBEACOPP at 5 years. **Results:** We enrolled 2,101 patients. 1,006 patients with negative PET-2 were randomly assigned to either standard eBEACOPP (n=504) or 4x eBEACOPP (n=502). The proportion of patients receiving radiotherapy was 3 % in total and did not dif-

fer between treatment groups. With a median follow-up of 54 months, estimated 5-year PFS in the per-protocol set was 91.2 % (88.3-94.1) with standard eBEACOPP and 92.1 % (89.3-94.9) with 4x eBEACOPP (difference +0.9 %, 95 % CI -3.1-4.9 excluding the non-inferiority margin of -6 %). In the standard eBEACOPP group, 95 % had at least one acute hematological toxicity grade 3-4 compared with 90 % in the 4x eBEACOPP group, including severe infections in 75 (15 %) and 40 (8 %) patients, respectively. Estimated 5-year overall survival (OS) in the per-protocol set was 95.7 % (93.7-97.6) with standard eBEACOPP and 97.7 % (96.2-99.3) with 4x eBEACOPP (log-rank p=0.006). **Conclusion:** Early response to the eBEACOPP regimen determined by FDG-PET allows a clinically relevant reduction of the cumulative treatment intensity from standard to only 4 cycles without loss of lymphoma control. The improved tolerability of the shortened treatment strategy results in a significant OS benefit for our patients. As both PFS and OS reach unprecedented rates, we feel safe to strongly recommend this PET-guided eBEACOPP de-escalation strategy for patients with advanced-stage HL whenever cure is the primary treatment goal.

OP-544

Experimental validation of absolute SPECT/CT quantification for response monitoring in breast cancer

A. Collarino[1], L. M. Pereira Arias-Bouda[1,2], R. A. Valdés Olmos[1,3,4], P. van der Tol[5], P. Dibbets-Schneider[1], L. de Geus-Oei[1,6,7], F. H. P. van Velden[1,5]; [1]Section of Nuclear Medicine, Department of Radiology, Leids Universitair Medisch Centrum, Leiden, NETHERLANDS, [2]Department of Nuclear Medicine, Alrijne Ziekenhuis, Leiderdorp, NETHERLANDS, [3]Interventional Molecular Imaging Laboratory, Department of Radiology, Leiden University Medical Center, Leiden, NETHERLANDS, [4]Department of Nuclear Medicine, The Netherlands Cancer Institute – Antoni van Leeuwenhoek Hospital, Amsterdam, NETHERLANDS, [5]Medical Physics, Department of Radiology, Leids Universitair Medisch Centrum, Leiden, NETHERLANDS, [6]Biomedical Photonic Imaging Group, MIRA Institute, University of Twente, Enschede, NETHERLANDS, [7]Department of Radiology and Nuclear Medicine, Radboudumc, Nijmegen, NETHERLANDS.

Purpose: ^{99m}Tc-sestamibi (MIBI) is widely used for breast cancer studies. Recent developments in iterative image reconstruction enable absolute (semi-)quantification of SPECT/CT studies by incorporating compensation for collimator-detector response attenuation and scatter, and resolution recovery into the reconstruction process (Evolution; GE Healthcare, USA). The aim of this experimental study was to assess quantitative accuracy of Evolution for clinical MIBI breast cancer SPECT/CT studies. **Materials and Methods:** Phantoms were filled with MIBI and acquired on a SPECT/CT gamma-camera (Discovery NM/CT 670 Pro; GE Healthcare) using a low-energy, high-resolution collimator, non-circular orbit, step-and-shoot mode and 120 views. A low-dose CT scan was acquired for attenuation correction purposes. All SPECT data were reconstructed using Evolution with a 128x128 matrix without zoom. Firstly, a NEMA Image Quality phantom containing six spheres was filled with a background activity concentration of 3.6 kBq/ml, reflecting clinical MIBI up-

take in the breast, with a sphere-to-background ratio of 10:1. This phantom was acquired using 20 sec per view and reconstructed using up to 8 iterations (10 subsets) to assess (1) the convergence of Evolution and (2) the recovery coefficients (RC) of standardized uptake values (SUV_{mean} obtained using a 42, 50 and 70% isocontour, and SUV_{max}). Secondly, a Jaszczak phantom (activity concentration: 38 kBq/ml) was acquired with 1 to 24 sec per view in order to assess the performance of Evolution under different count statistics. **Results:** For background compartment of the NEMA phantom, the activity concentration converged after 3 iterations, while the coefficient of variation increased from 12.3 to 44.9% with increasing number of iterations. For the remainder of the study 4 iterations were applied to ensure convergence. Depending on the count statistics, the accuracy of the reconstructed activity concentration varied between -2.61 to 5.51% (volume-of-interest covering the entire phantom) and from 9.66 to 6.49% (2 litre volume-of-interest placed in the centre of the phantom). RC of SUV_{max} was 1.56, 1.82, 1.76 and 1.47 for spheres with 37, 28, 22 and 17 mm diameter, respectively, while RC of SUV_{mean} was 0.94, 1.00, 0.95 and 0.71 (42% isocontour), 1.02, 1.12, 1.06 and 0.70 (50% isocontour), and 1.18, 1.31, 1.32 and 1.12 (70% isocontour). **Conclusion:** Absolute (semi-)quantification of SPECT/CT MIBI breast studies seems feasible (<10% deviation) when a 42% isocontour is used for delineation for tumours of at least 22 mm diameter. However, with tumour shrinkage, response evaluation should be handled with care, especially when using SUV_{max}.

OP-545

Somatostatin antagonist theranostic pair ^{68}Ga-OPS202 and ^{177}Lu-OPS201 for well-differentiated neuroendocrine tumors (NETs)

D. Reidy, N. Pandit-Taskar, S. Krebs, J. O'Donoghue, N. Raj, E. Cruz, H. Pham, A. Lashley, L. Bodei, W. A. Weber; *Memorial Sloan Kettering Cancer Center, New York, NY, UNITED STATES OF AMERICA.*

Aims: Radiolabeled somatostatin receptor 2 (SSTR2) antagonists have shown higher tumor uptake and tumor-to-organ ratios than agonists in preclinical models. We performed a phase I study to evaluate the safety and radiation dosimetry of the SSTR2 antagonists ^{68}Ga-OPS202 and ^{177}Lu-OPS201 (^{68}Ga/^{177}Lu-DOTA-JR11) in patients (pts) with metastatic well-differentiated NETs (NCT02609737). Efficacy and tolerability data after ^{177}Lu-OPS201 treatment were recorded. **Methods**: Pts with RECIST disease progression underwent a ^{68}Ga-OPS202 PET/CT to confirm in-vivo binding of the SSTR2 antagonists and, if positive, underwent treatment with 3 doses of ^{177}Lu-OPS201. The first 50 mCi dose of ^{177}Lu-OPS201 was used to calculate tumor and normal organ dosimetry. ^{177}Lu-OPS201 was then administered in divided doses ≤200 mCi for the 2nd and 3rd fractions, 8-10 weeks apart, based on dosimetry. **Results:** 19 pts enrolled (primary tumors: 1 broncho-pulmonary, 7 small-bowel, 8 pancreatic, 1 gastric, 1 rectal, and 1 renal NET). Average age was 55 y (22-73 y), 52% female; mean number of prior treatments was 3. All pts received 1 therapeutic dose of ^{177}Lu-OPS201, 7 pts received 2 doses. All tumors were visualized by ^{68}Ga-OPS202 PET/CT. With the exception of the kidneys and bladder, no organ demonstrated uptake of ^{68}Ga-OPS202 above background. Tumor radiation doses ranged from 0.15 Gy/mCi to 0.48 Gy/mCi. Subacute hematologic toxicity after cycle 1 was generally mild-moderate (G3 leukopenia in 2/19, reversed before cycle 2). 4/7 (57%) pts that received the second dose of ^{177}Lu-OPS201 exhibited G4 hematological toxicities, which occurred 4-6 weeks after administration. G3/4 toxicities in the four pts resolved to G2 or lower in 12-19 weeks; none of these pts demonstrated fever, infection, bleeding, or renal toxicity. Substantial efficacy was observed: 1 patient achieved a CR (1/19, 5%), 32% PR (6/19), 47% SD (9/19) and 16% POD (3/19). 1-year PFS was 67%. **Conclusions:** In this trial of heavily treated NETs, preliminary data are promising for the use of ^{68}Ga-OPS202/^{177}Lu-OPS201 as a theranostic combination for imaging and therapy. Additional studies are planned to optimize the therapeutic dose to minimize hematologic toxicity. The study was partly funded by the NET Research Foundation.

OP-546

Comparison of 18F-FDG PET/MRI and MRI for primary evaluation and treatment planning of cervical cancer patients

J. Grueneisen[1], T. Sarabhai[1], B. Schaarschmidt[2], M. Forsting[1], K. Herrmann[1], L. Umutlu[1]; [1]University Hospital Essen, Essen, GERMANY, [2]University Hospital Düsseldorf, Düsseldorf, GERMANY.

Purpose: To compare the diagnostic performance of integrated PET/MRI and MRI for primary tumor staging of cervical cancer patients as well as to investigate whether discrepancies of staging results between the two imaging modalities lead to different treatment recommendations. **Subjects & Methods:** 53 consecutive patients with histopathological confirmation of primary cervical cancer were prospectively enrolled for a whole-body 18F-FDG PET/MRI examination prior to the initiation of definitive treatment or lymphadenectomy. Two experienced physicians analyzed the resulting MRI data, followed by a second reading session of the PET/MR datasets. Both readers were asked to perform a dedicated TNM-staging in accordance to the 7th edition of the AJCC staging manual. Subsequently, the results of MRI and PET/MRI were discussed in a simulated interdisciplinary tumor board. The participants were blinded to the results from the pathology report of diagnostic lymphadenectomy and definitive surgical treatment as well as to findings in follow-up imaging. Finally, the most appropriate treatment strategy was determined for each patient, based on the information from clinical evaluation and imaging findings in 1. MRI and 2. PET/MRI. **Results:** PET/MRI and MRI allowed for correct determination of the T-stage in 45/53 (85%) and 46/53 (87%) cases, respectively. Furthermore, PET/MRI revealed a higher sensitivity and specificity than MRI alone for the detection of nodal positive patients (83% and 90% vs. 71% and 77%) and the identification of patients with distant metastases (87% and 92% vs. 67% and 90%). Comparing the staging results of MRI and PET/MRI revealed discrepant findings in 17 (32%) cases, which led to differences in treatment recommendations for 12 patients (23%). Among them, PET/MRI over- (n=1) and underestimated

(n=1) the actual tumor stage in two patients, which affected therapeutic decisions. In one additional patient, PET/MRI over-estimated the actual tumor stage, which was also falsely rated with MRI alone. However, incorrect ratings in MRI did not re-sulted in false treatment recommendations. Conversely, MRI revealed incorrect staging results in 9 patients (n=3, overesti-mation; n=6 underestimation). PET/MRI enabled determination of the correct tumor stage in 7 of those 9 patients. In the re-maining two cases, staging results of PET/MRI still provided cor-rect treatment recommendations. In 5 patients (11%), different imaging findings in MRI and PET/MRI did not lead to changes in therapeutic decisions. **Conclusion:** Our results demonstrate the successful application and diagnostic advantage of integrated PET/MRI imaging over MRI alone for whole-body tumor staging of cervical cancer patients, enabling more accurate treatment planning.

OP-547

[123/131I]IMAZA as a new theranostic tool in patients with advanced adrenocortical carcinoma

A. Schirbel[1], C. Blümel[1], B. Heinze[2], A. Plaß[2], C. T. Fuß[2], F. Megerle[2], T. Deutschbein[2], M. Fassnacht[2], M. Kroiss[2], H. Hänscheid[1], A. K. Buck[1], S. Hahner[2]; [1]University of Wuerzburg, Department of Nuclear Medicine, Wuerzburg, GERMANY, [2]University of Wuerzburg, Department of Medicine I, Division of Endocrinology and Diabetes, Wuerzburg, GERMANY.

Introduction: We have recently developed the metomidate analogue [123/131I]IMAZA as radiotracer for molecular imaging in adrenal tumours and radiotherapy in adrenocortical carci-noma (ACC). IMAZA selectively binds to both aldosterone syn-thase and 11ß-hydroxylase and showed in mice experiments improved binding properties to target tissue compared to io-dometomidate (IMTO). Therefore we evaluated [123I]IMAZA for imaging in a series of 36 consecutive ACC-patients with the aim to investigate the feasibility of a subsequent [131I]IMAZA-endo-radiotherapy. **Subjects & Methods:** Imaging was performed for evaluation of a potential endoradiotherapy of advanced ACC (n=36). SPECT/CT and planar images were obtained up to 24 h after i.v. administration of 180 MBq [123I]IMAZA. Additional [123I]IMTO imaging was performed in 3 patients within 1 week. Clinical and laboratory data were collected before and after im-aging. Blood samples were drawn and the metabolic stability of the tracer was analysed by radio-HPLC. After individual do-simetry first [131I]IMAZA-endoradiotherapies were performed in suitable patients. Results: [123I]IMAZA proved to be a tracer that specifically accumulated in adrenocortical tissue similar to [123I]IMTO. Uptake in the tumour lesions was heterogeneous indicat-ing variable expression of the target enzymes CYP11B1 and 2. We observed rapid clearance of unbound tracer and an up to 5-fold higher tumour uptake compared to IMTO, which signifi-cantly improved imaging quality. Analysis of blood samples by radio-HPLC demonstrated a significant higher metabolic stabil-ity of the tracer. Strong tracer uptake in all tumour lesion was seen in 42% of patients, mixed uptake in 18% and no uptake was documented in 40%. Endoradiotherapies using [131I]IMAZA

in 7 selected patients were performed with activities up to 30 GBq and were well tolerated without serious acute toxicities. High and long-lasting uptake was observed in all known lesions and resulted in tumour doses up to 265 Gy. **Conclusion:** [123I]IMAZA-SPECT shows more selective binding properties and fa-vourable metabolic stability than the reference [123I]iodometo-midate. Tracer uptake is highly specific, however the variable expression of CYP11B1/2 limits the diagnostic sensitivity. About 40% of patients are potential candidates for endoradiotherapy with [131I]IMAZA. This radiopharmaceutical has an excellent tox-icity profile and is a promising therapeutic approach in selected patients with advanced ACC.

OP-548

ImmunoPET imaging to assess target engagement: Experience from 89Zr-anti-HER3 mAb (GSK2849330) in patients with solid tumors

A. Mcgeoch[1,2], C. Menke-van der Houven van Oordt[3], M. Bergstrom[1], I. McSherry[1], D. Smith[4], M. Cleveland[1], O. Hoekstra[3], D. Vugts[3], A. Weber[5], I. Freedman[5], M. Huisman[3], C. Matheny[5], G. van Dongen[3], S. Zhang[5]; [1]GSK, Stevenage, UNITED KINGDOM, [2]University of Cambridge, Cambridge, UNITED KINGDOM, [3]VU University Medical Centre, Amsterdam, NETHERLANDS, [4]PAREXEL International, Durham, NC, UNITED STATES OF AMERICA, [5]GSK, King of Prussia, PA, UNITED STATES OF AMERICA.

Aim: Maximum tolerated dose (MTD) has historically guided dose selection in oncology. For targeted treatments and bio-logics, this approach risks exposing patients to unnecessary tox-icity and drives unsustainably high costs. A logical alternative is measuring maximal tumor target occupancy using positron emission tomography (PET) imaging with radiolabelled drugs. In this immunoPET study, we investigated biodistribution and tumor uptake of 89Zr-labelled anti-HER3 monoclonal antibody (mAb) GSK2849330, and evaluated target engagement as a function of mass dose to inform a rational dose for future effi-cacy testing. **Methods:** 89Zr-GSK2849330 distribution was mon-itored in 6 patients with HER3-positive tumors not amenable to standard treatment with PET at up to 3 occasions after adminis-tration. Uptake in normal tissues and tumor sites was quantified as standard uptake value (SUV) and through modelling related to plasma radio-pharmacokinetics. Tumor accumulation rate was established with two subsequent tracer administrations in each patient combined with different doses of unlabelled mAb. First, a low dose of 89Zr-GSK2849330 was administered to serve as baseline, and subsequently dose-dependent inhibition of 89Zr-GSK2849330 uptake in tumor tissues was evaluated after pre-dosing with increasing amounts of unlabelled GSK2849330, enabling calculation of the 50% inhibitory mass dose (ID50) of target-mediated uptake of 89Zr-mAb by unlabelled mAb. **Re-sults:** A baseline total mass dose of 8mg was found to give optimal signal in tumours. Accumulation of 89Zr-GSK2849330 was also observed in certain normal tissues such as liver and spleen. 89Zr-GSK2849330 uptakes were observed and quantita-tively measurable in tumors of 5 out of 6 patients with increas-ing accumulation seen over time on days 2 and 5 after dosing.

Pre-dosing with unlabelled mAb reduced the tumor uptake rate of ^{89}Zr-GSK2849330 in a dose-dependent manner with an ID50 of 2 mg/kg. Saturation of ^{89}Zr-mAb uptake by tumors was seen at the highest doses (30mg/kg) of competing unlabelled mAb used. **Conclusion:** In this immunoPET study with^{89}Zr-GSK2849330, we defined the mAb distribution in patients with HER3-positive tumors. The dose-dependent inhibition of tumor uptake of ^{89}Zr mAb by unlabelled mAb confirmed target engagement, i.e. the specific binding and internalization of anti-HER3 antibody by the HER3 receptors in the tumor tissues. This study further validates the use of immunoPET approach to non-invasively and quantitatively measure target engagement at the site of action (tumor) and to directly visualize tissue drug disposition in humans which offers the potential for evidence based dose selection. This study is sponsored by GSK with ClinicalTrials.gov Identifier: NCT02345174.

Orsola Malpighi, University of Bologna, Bologna, ITALY, [7]Nuclear Medicine Unit, Department of Imaging, SDN Foundation, Napoli, ITALY, [8]Nuclear Medicine Unit, Cancer Center, Humanitas Hospital, Rozzano, Milano, ITALY, [9]Nuclear Medicine Unit, Department of Imaging, Azienda Ospedaliera Universitaria Integrata di Verona, Verona, ITALY, [10]Department of Biomedicine and Prevention, University of Rome Tor Vergata, Roma, ITALY, [11]Nuclear Medicine Unit, Department of Imaging, Medicina Futura IOS, Acerra, Napoli, ITALY, [12]Department of Nuclear Medicine, Hospital of Bolzano, Bolzano, ITALY, [13]Department of Advanced Biomedical Sciences, University of Naples Federico II, Napoli, ITALY, [14]Institute of Nuclear Medicine, Università Cattolica del S. Cuore, Roma, ITALY.

Background: The aims were to:1)determine the performance of FDG-PET/CT in SPN by considering categorical and continuous data analysis;2)assess if continuous data were correlated with intra- and extra-thoracic pathological FDG uptake and 3) evaluate if clinical, demographical or morphological variables are correlated with the presence of pathological FDG uptake (intra- and extra-thoracic) other than the lung nodule(LN). **Methods:** Between 2014 and 2016,we retrospectively selected 225consecutive patients(age:67years)investigated by FDG-PET/CT for characterization of SPN. Patients with prior cancer history and candidates to PET/CT for the staging of lung cancer were excluded. Patients were stratified, according to clinical and instrumental pre-test probability of malignancy(Brock model), in low, intermediate and high category risk. FDG uptake in SPN was visually assessed by a 4-point scoring system(from 0=absent to 3=intense)and by semiquantitative analysis of the LN(in terms of SUVmax), in the blood pool(BP)and in the liver(L)(both in terms of SUVmean). **Results:** SPN histology was available in 164 patients, while follow-up in 61. SPN was malignant in 111 patients and benign in 114. In all 225 patients, by considering categorial data(FDG uptake ≥2 vs. <2), sensitivity, specificity, positive predictive value(PPV), negative predictive value(NPV) and accuracy of FDG-PET/CT for the characterization of SPN were 79%, 75%,75%, 79% and 77%, respectively. Based on the Brock model, sensitivies and PPV were elevated in patients with intermediate and high risk patients(75% and 88%, 69% and 88%, respectively),while specificity and NPV were higher in low risk category. At Roc analysis, the cut-offs for better discriminating between benign and malignant LNs were 1.60(sens: 81% and spec. 81%)and 1.21(sens: 81% and spec. 80%)respectively for SUVmax/SUVmeanBP and SUVmax/SUVmeanL ratios. In patients at intermediate and high risk of malignancy, by including the SUVmax/SUVmeanBP ratio, the specificities shift from 71% to80% and from 64% to89%, respectively. In all patients, SUVmax/SUVmeanBP and SUVmax/SUVmeanL ratios were significantly higher in patients with intra-thoracic lesions than without(both <0.05). Furthermore, at logistic multivariate analysis, a high malignancy risk and a moderate FDG uptake in the LN were predictors of intra-thoracic pathological uptake(both p<0.05)**. Conclusions:** Visual FDG PET/CT, by 4 point scale assessment, has an acceptable performance in SPN patients, but it can significantly improve by considering semiquantitative continuous data, particularly in patients with intermediate and high risk of malignancy. Moreover, continuous data can be useful for the evaluation of disease spread in intra-thoracic site, but stratification for risk category and for FDG uptake in the LNs are predictors of intra-thoracic pathological sites.

OP-550

^{68}GaNeoBOMB1 in oligometastatic GIST: first results from a Phase-I/IIa study

L. Gruber[1], C. Uprimny[1], F. Orlandi[2], H. Margreiter[1], M. F. Mariani[2], W. Jaschke[1], C. Decristoforo[1], I. Virgolini[1]; [1]Medical University Innsbruck, Innsbruck, AUSTRIA, [2]Advanced Accelerator Applications S.r.l., Colleretto Giacosa/Ivrea, ITALY.

Introduction: Molecularly targeted therapy with Tyrosine Kinase Inhibitors (TKI) revolutionized the treatment of Gastrointestinal Stromal Tumours (GIST) but resistance to these drugs represents an important clinical challenge. Gastrin-releasing peptide receptor (GRPR) are highly overexpressed in GIST and present a promising target for molecular imaging and therapy. Within the MITIGATE project (Closed-loop Molecular Environment for Minimally Invasive Treatment of Patients with Metastatic Gastrointestinal Stromal Tumours, EU-FP7, grant agreement no 602306) a clinical trial in patients with TKI resistant GIST

was initiated in 2016. ^{68}Ga-NeoBOMB1 is a novel GRPR antagonist, which can be prepared using a kit-based preparation and was selected for this study. **Materials and Methods:** a Phase-I/IIa clinical trial (EudraCT 2016-002053-38) to evaluate safety, biodistribution, dosimetry and preliminary diagnostic performance of [68]Ga- NeoBOMB1 in patients with advanced TKI-treated GIST using PET/CT was approved by the EC and competent authority. ^{68}Ga-NeoBOMB1 is prepared using a simple kit based procedure based on a licensed [68]Ge/^{68}Ga generator. In total, 12 patients with presence of at least one surgically untreatable primary or metastatic, histologically confirmed GIST are planned to be studied with a minimum 50% of those showing documented TKI-resistance. Histopathological correlation with GRPR expression by IHC is planned in 6 patients. PET/CT includes dynamic and 1, 2 and 3-4h static PET imaging. Blood and urine sampling is performed to provide PK data. Safety parameters including vital signs, cardio-vascular, and biochemistry in blood and urine are assessed. **Results**: So far 2 TKI-resistant metastatic GIST patients were included. Kit based preparation of ^{68}Ga-NeoBOMB1 resulted in >97% radiochemical purity. ^{68}Ga-NeoBOMB1 showed favourable PK with exclusive renal excretion pattern starting within few minutes after injection and a physiologic high uptake in pancreas already 30 min p.i. Stability of ^{68}Ga-NeoBOMB1 in blood samples was high. No product-related adverse events were reported up to 2 weeks after application. Liver metastasis showed increasing SUV values with improving contrast over time. **Conclusion:** ^{68}Ga-NeoBOMB1 is a promising agent to image GIST based on the high overexpression of GRPR and so far has shown an excellent safety profile. More patients are currently enrolled and will be presented providing more information on GRPR targeting properties of this agent in patients with TKI resistant GIST.

OP-551

^{18}F-FDG PET/CT for treatment response assessment in classical Hodgkin Lymphoma (cHL), in the era of innovative immunomodulatory PD-1 blocked (nivolumab) therapy

I. Sandler[1], A. Broccoli[2], P. Castellucci[1], C. Nanni[1], C. Pellegrini[2], F. Quirini[2], P. Zinzani[2], S. Fanti[1]; [1]Nuclear Medicine Unit, University of Bologna, S.Orsola-Malpighi Hospital, Bologna, ITALY, [2]Institute of Hematology and Medical Oncology "L.&A. Seràgnoli", University of Bologna, S.Orsola-Malpighi Hospital, Bologna, ITALY.

Introduction and Aim: The intersection between immune surveillance and tumor have led to broad therapeutic advances that are now being studied in all cancer types. The IgG4 subclass PD-1 inhibiting antibodies, nivolumab and pembrolizumab, are approved for treating advanced melanoma and non-small cell lung cancer. PD-1 ligands are also overexpressed by Reed-Sternberg cells in cHL, therefore nivolumab was recently approved by the US FDA for patients with relapsed or refractory cHL. As a part of an ongoing prospective study we report our initial experience with ^{18}F-FDG PET/CT for nivolumab treatment response assessment for cHL. **Methods:** In our Center, 7 patients (5 males and 2 females, mean age 37 y.o) with relapsed or refractory cHL

are under treatment with nivolumab (3mg/kg every two weeks) since 2016. All patients underwent ^{18}F-FDG PET/CT no more than 4 weeks prior to first nivolumab administration to define disease baseline stage: 2 patients presented stage II, 2 stage III and 3 stage IV. All patients underwent 3 "interim" response assessment with ^{18}F-FDG PET/CT scan: at 2 month, 4 month and 6 month after the beginning of therapy. All ^{18}F-FDG PET/CT scans were performed according to standard procedure then were visually analyzed by two expert nuclear physicians. ^{18}F-FDG uptake was quantified by standardized uptake values (SUVmax). ^{18}F-FDG PET/CT results were classified for "immune-response" relatively to baseline as "complete" (CR; disappearance of all lesions), "partial" (PR; decrease of 50% tumor burden), "stable"(SD) and "progressive" (PD; 25% increase of tumor burden). ^{18}F-FDG PET/CT results were compared to clinical hematologic response assessment (symptoms, physical examination and laboratory). **Results:** While all patients presented complete clinical hematologic remission in 6 month of therapy (no disease symptoms, negative physical examination and laboratory results), no ^{18}F-FDG PET/CT scan showed CR after the first, second and third "interim" scans. After the third "interim" scan 3 patients showed ^{18}F-FDG PET/CT PD and 4 PR. Only 1 patient showed ^{18}F-FDG PET/CT down-staging (stage IV to stage II). No correlation between baseline stage and ^{18}F-FDG PET/CT therapy response. 4 of 7 patients showed ^{18}F-FDG uptake referred to pneumonitis and/or thyroiditis and/or rash and/or gastritis known as adverse events of the therapy. **Conclusions:** ^{18}F-FDG PET/CT findings in immunomodulatory treatment response assessment do not correlate with clinical and hematological remission. More studies should be done to understand and define this phenomenon (tumor "flare"? "Pseudo-progression"?) deciding then the right timing of ^{18}F-FDG PET/CT response assessment in cHL.

Gender differences in the cerebral uptake of ^{18}F-FDG

*J. W. A. Sijbesma, **A. van Waarde**, D. Vállez García, H. H. Boersma, R. H. J. A. Slart, R. A. J. O. Dierckx, J. Doorduin; University of Groningen, Groningen, NETHERLANDS.*

An important issue in rodent imaging is the question whether it is possible to use both female and male animals in tracer development and evaluation, rather than animals from a single sex. For this reason, we have made repeated ^{18}F-FDG scans of the brain of adult rats (either males, or females at different phases of the estrous cycle). Our study was aimed to answer the following questions: a. Are there differences in brain metabolism between male and female rats? b. Are there differences in the cerebral ^{18}F-FDG uptake of female rats at different phases of the estrous cycle? and c. Is the test-retest variability of ^{18}F-FDG PET different in males and females? **Methods:** Long-Evans rats

(age 1 yr) were divided into three groups: 1. Males (n=8), 2. Females in metestrous (low estrogen levels, n=8), and 3. Females in proestrous (high estrogen levels, n=8). Two small animal PET scans using ^{18}F-FDG and rapid arterial blood sampling were made at an interval of 10 days in subjects anesthetized with isoflurane in oxygen (thus, 48 scans were made in total). Body temperature, heart rate, glucose levels in plasma and blood oxygenation were monitored in all rats during the scans. A preliminary analysis was performed on data from the entire brain. Data from predefined brain regions will be analyzed in the near future, using kinetic modeling. **Results:** Females showed a significantly higher brain uptake of ^{18}F-FDG than males, particularly in the initial scan (+40%, P < 0.0001). Higher estrogen levels were associated with increased brain metabolism, since the accumulation of ^{18}F-FDG was 11.5% higher in proestrous than in metestrous or other phases of the estrous cycle (P < 0.02; in the second scan, a few animals were in diestrous or estrous rather than the desired proestrous or metestrous phase). Cerebral glucose metabolism in the test and retest condition was identical in males, but females showed a significant decline (-10.5 ± 2.6%). **Conclusion:** Based on the results for this particular model, the mixing of sexes or the mixing of female rats in different phases of the estrous cycle in tracer evaluation protocols will result in an impaired test-retest stability of the PET data and a need for larger group sizes to maintain the same statistical power in group comparisons.

OP-553

Brain Metabolic Response to Prolonged Starvation: a micro-PET study

*A. Orengo[1], **A. Buschiazzo**[2], L. Emiomite[3], S. Ravera[4], V. Cossu[1], S. Bruno[5], A. Bellini[2], L. Raffaghello[6], F. Di Giulio[1], G. Bianchi[6], S. Morbelli[1], C. Marini[1,7], G. Sambuceti[1,2]; [1]Nuclear Medicine Unit, IRCCS AOU San Martino-IST, Genoa, ITALY, [2]Department of Health Sciences, University of Genoa, Genoa, ITALY, [3]Animal facility, IRCCS AOU San Martino-IST, Genoa, ITALY, [4]Department of Pharmacy, Biochemistry Laboratory, University of Genoa, Genoa, ITALY, [5]Department of Experimental Medicine, University of Genoa, Genoa, ITALY, [6]Laboratory of Oncology, G. Gaslini Institute, Genoa, ITALY, [7]CNR Institute of Bioimages and Molecular Physiology, Milan, ITALY.*

Introduction: Clinical use of brain imaging of FDG uptake relies on the assumption that this tracer accurately delineates overall glucose consumption (MRGlu) in central nervous system. We recently documented that starvation (STS) in cancer down regulates glycolysis with an increased dependency on oxidative phosphorylation. The present study was designed whether prolonged starvation causes a simultaneous decrease in glucose consumption and FDG uptake in mouse brain. **Subjects & Methods**: All animal experiments were reviewed and approved by the Italian Ministry of Health. Six-weeks-old BALB/c mice were divided into "controls" (n=7) that did not receive any treatment and "STS" (n=6) submitted to 48 hours deprivation of food before imaging. After anesthesia, both groups underwent dynamic microPET imaging (Albira, Bruker, US) according to a protocol previously validated in our lab, to estimate MRGlu by

Patlak analysis. In 2 further mice per group, not submitted to imaging, the brain was harvested soon after sacrifice by cervical dislocation. Brains were placed in the Petri dish of Ligand tracer instrument (Ridgeview, Se) whose rotation permits to cyclically move the organ from the incubation medium to the focus of a counting detector every 30 seconds. Incubation medium was enriched with 12.5 mM glucose and 6 MBq FDG. Time trend of organ radioactivity content was monitored for one hour and Patlak estimate of MRGlu was compared with directly measured glucose disappearance from incubation medium. At the end of the experiment, phospho-fructo-kinase (PFK), hexose-6-phosphate dehydrogenase (H6PD), glucose-6-phosphate-dehydrogenase (G6PD) and β-hydroxy-butyrate-dehydrogenase (β-HBD) activity were assayed in homogenates brains by standard spectrophotometric methods. **Results**: Micro-PET analysis evidenced that two-days STS significantly reduces brain MRGlu (from 14.2±3.1 nM x min^{-1} x g^{-1} to 4.6±2.3 nM x min^{-1} x g^{-1}, p<0.001 vs. controls) and similar results were obtained with ex vivo experiments. Further studies on homogenates brains showed an increase in β-HBD activity, key enzyme for ketone bodies catabolism in brain. Interestingly, PFK activity decreased to 38.9% suggesting a reduction in glycolytic flux. Moreover, the activity of cytosolic G6PD was reduced to 41.7% while the ER counterpart H6PD activity remained unchanged. **Conclusion**: The present data documented that STS caused a reduction of MRGlu probably depending on a metabolic shift of brain metabolism to oxidation of ketone bodies and to catabolism of glucose by a new ER pathway triggered by H6PD.

OP-554

Altered Insulin-Dependent Brain Glucose Metabolism During Obesity Depends On Specific Brain Areas

C. Malbert[1], S. Bahri[2]; [1]INRA, Saint-Gilles, FRANCE, [2]University of Tunis, Tunis, TUNISIA.

There is a general agreement for insulin mediated changes in brain metabolism in insulin resistance. However, the association of this phenomenon with obesity alone is unclear especially when quantitative data of glucose metabolism were obtained. Using quantitative PET, the extend of these metabolic changes involves either the entire brain (Hirvonen, 2011) or brain specific regions - some with increased and others with decreased glucose metabolism (Anthony et al, 2006). Finally, the mechanisms underlying theses modifications are unknown being potentially dependent on forward and reverse glucose transport and intracellular phosphorylation. We aimed to evaluate these modifications using quantitative PET before and after diet induced obesity either in fasting insulin or during euglycemic hyperinsulinemic clamp condition. Ten adults mini pigs were scanned using [18]FDG before and after 5 months of obesogenic diet given at 150% the recommended caloric intake (288 kcal/kg body weight wt$^{0.75}$). The extend of fat deposition was evaluated using CT scan and the resting energy expenditure was quantified using indirect calorimetry. PET images were acquired dynamically either in fasted state or during an isoglycemic-hyperinsulinemic clamp (120mU.kg^{-1}.h^{-1}). Glucose uptake rates were obtained

through model analysis of PET data and continuous arterial radioactivity measurement. Pixel-wise modelled brain volumes were also reconstructed and analysed using SPM. All animals gained weight (75.3 ± 6.01 vs 32.7 ± 2.90 kg) as a result of equal increase in visceral and subcutaneous fat-mass. The energy expenditure was about doubled (1430 ± 43.2 vs 904 ± 34.9 kcal/day) and the whole body insulin sensitivity was halved (3.9 ± 0.32 vs 6.4 ± 0.21 dL/kg.min/µU/mL.1E^{-3}). In fasting state, CMRglu was slightly but significantly less in obese than in lean condition (9.5 ± 0.47 vs 11.8 ± 1.54 µmol/min/100g) and the same reduction was found brain-wide. During insulin stimulation, CMRglu of lean animals was unchanged compared to fasting irrespective of the brain structure. On the contrary, whole brain CMRglu was significantly increase by insulin in obese compared to lean condition as a result of increased uptake in the insula, prefrontal cortex and striatum (20.6 ± 0.30 vs 12.5 ± 0.30 µmol/min/100g). This was the consequence of an increased glucose transport only. In conclusion, in the fasting state, the obese brain behaves like the remaining of the body through an overall reduction of the glucose metabolism. On the contrary, during insulin clamp, several brain structures increase their glucose metabolism in obese condition as a result of an increased glucose transport.

Brain [11C]PK11195 and [18F]FDG PET imaging in a rat model of postoperative cognitive dysfunction

E. Kurtys[1,2], I. B. Hovens[2], C. C. Real[3], P. Kopschina Feltes[4], D. Vállez García[4], U. L. M. Eisel[2], R. G. Schoemaker[2], J. M. Verkuyl[5], L. M. Broersen[5], H. C. Klein[4], R. A. J. O. Dierckx[4], J. Doorduin[4], E. F. J. de Vries[4]; [1]King's College London, London, UNITED KINGDOM, [2]University of Groningen, Groningen, NETHERLANDS, [3]University of São Paulo, São Paulo, BRAZIL, [4]University of Groningen, University Medical Center Groningen, Groningen, NETHERLANDS, [5]Nutricia Research, Utrecht, NETHERLANDS.

Aim: Postoperative cognitive dysfunction (POCD) is a common complication after surgery that can have a long-lasting negative impact on the patient's quality of life. Although the underlying mechanism is still unknown, evidence suggests that neuroinflammation may play an important role. Here we aimed to confirm the presence of neuroinflammation in a rat model of POCD and investigated the impact of the surgical procedure on brain metabolism. Nutrition is believed to affect cognition and brain metabolism and could modulate neuroinflammation. We therefore also evaluated the impact of a multi-nutrient supplementation diet containing anti-inflammatory ingredients on surgery-induced biochemical alterations in the brain and on POCD symptoms. **Materials and Methods:** POCD after major abdominal surgery in humans was mimicked in rats by exteriorizing the gastrointestinal tract and clamping the mesenteric artery for 30 min. To assess the validity of the model, behavioral changes were evaluated in the first postoperative week. The effects of surgery on neuroinflammation and brain glucose metabolism were monitored noninvasively by positron emission tomography (PET) and postmortem by immunohistochemistry. To assess the effect of nutrition, rats were fed a control diet or

investigational diet starting either 2 weeks before or immediately after the surgical intervention. **Results:** Major surgery caused significant bodyweight loss, reduced exploratory behavior, increased anxiety and tended to decrease spatial memory. [11C]PK11195-PET imaging and immunohistochemistry confirmed the presence of neuroinflammation in several brain regions after surgery. [18F]FDG-PET imaging revealed both increased and decreased brain metabolism in distinct parts of the brain. Dietary intervention started prior to surgery had a positive impact on recovery, resulting in faster gain in bodyweight and normalization of exploratory behavior and spatial memory. This improvement was accompanied by a reversal of astrocyte activation in the periventricular zone and a normalization of brain metabolism in part of the motor cortex. Dietary intervention started after surgery reversed astrocyte activation in cerebellum and the periventricular zone and decreased brain metabolism in the piriform cortex, but had no beneficial effect on anxiety and spatial memory. **Conclusion:** This study shows that major surgery can be accompanied by neuroinflammation and changes in glucose metabolism in several brain regions. Preventive intervention with a diet containing anti-inflammatory nutrients can affect neuroinflammation and brain metabolism and has a positive effect on the recovery from abdominal surgery in rats. These results indicate that a dietary intervention can have an effect on brain physiology and warrant further investigation of this concept.

OP-556

Muscimol Reduces D2 Receptor Binding in the Mesolimbothalamic System of the Rat

S. Nikolaus[1], H. Wittsack[1], M. Beu[1], M. A. De Souza Silva[2], C. Antke[1], F. Wickrath[1], A. Müller-Lutz[1], G. Antoch[1], J. P. Huston[2], H. Müller[1], H. Hautzel[1]; [1]University Hospital Düsseldorf, Düsseldorf, GERMANY, [2]Heinrich-Heine University, Düsseldorf, GERMANY.

Purpose/Introduction: Muscimol (MUS) acts as an highly selective GABA(A) receptor (R) agonist. We have previously shown that MUS decreased D2R binding in the rat neostriatum (1). In the present study, we assessed the effect of MUS on D2R binding in neocortical and subcortical regions, employing dedicated small animal SPECT and MRT. **Subjects & Methods:** In 16 male Wistar rats, D2R binding was measured in baseline (BAS) and after application of MUS (1 mg/kg ip). After MUS challenge, motor/exploratory behavior was registered for 30 min in an open field using EthoVisionXT. Iodine-123-IBZM (26±4MBq) was injected 30 min post-challenge. Imaging data were acquired 45 min after radioligand application with the TierSPECT. Seven rats were scanned with a dedicated small animal MRT (MRS3000 Pre-clinical MRT, 3.0 T, MR Solutions, Guildford, UK) in order to gain morphological information. Based on the Paxinos rat brain atlas, regions of interest were defined on SPECT-MRT overlays. Estimations of the binding potential (BP) were obtained by computing ratios of the specifically bound compartments to the cerebellum for neostriatum (STR), ventral striatum (VSTR), thalamus (THAL), substantia nigra (SN), frontal (FC), motor (MC) and parietal cortex (PC) as well as an-

terior (aHIPP) and posterior hippocampus (pHIPP). **Results:** In BAS, BPs amounted to 2.82±.46 (STR), 2.53±.51 (VSTR), 1.92±.38 (THAL), 1.77±.39 (SN),1.65±.61 (FC), 1.56±.41 (MC), 1.18±.33 (PC), 1.49±.23 (aHIPP) and 1.47±.36 (pHIPP). After MUS, BPs were 1.92±.41 (STR), 2.40±.42 (VSTR),1.60±.41 (THAL), 1.27±.43 (SN), 1.25±.44 (FC), 1.41±.46 (MC),1.14±.30 (PC), 1.39±.30 (aHIPP) and 1.21±.40 (pHIPP). Reductions in STR, VSTR, THAL, SN and pHIPP were significant (.005≤p≤.012). In STR, VSTR, SN and pHIPP, D2R binding was negatively correlated with grooming in the first half and positively correlated with motor/exploratory behaviors in the second half of the testing time. **Discussion/Conclusion:** The MUS-induced reduction of D2R binding in STR, VST, THAL, SN and pHIPP implies an elevation of synaptic dopamine levels in these regions. Thereby, lower D2 receptor binding (and higher DA) in STR, VSTR, SN and pHIPP was associated with an increase of grooming in the first and a decrease of motor/exploratory behaviors in the second half of the testing time. Findings indicate direct GABAergic control over synaptic dopamine levels in the mesolimbothalamic system in relation to behavioral action. (1)Nikolaus et al. Pharmacol Biochem Behav 2017; 153: 76-87.

OP-557

Cross-Species Physiological Assessment of Brain Estrogen Receptor Expression Using 4FMFES PET Imaging

M. Paquette, S. Phoenix, J. A. Rousseau, O. Sarrhini, R. Lecomte; Université de Sherbrooke, Sherbrooke, QC, CANADA.

Introduction: There is evidence that the estrogen decline during and after menopause have cognitive impacts, suggesting a relationship between cognition and physiological estrogen stimulation. Previous autoradiography studies showed that many areas in the rat brain have a high estrogen receptor (ER) expression, especially in the hypothalamic region. In this work, retrospective analysis of preclinical and clinical data during evaluation of the ER PET tracer 4-fluoro-11β-methoxy-16α-[^{18}F]-fluoroestradiol (4FMFES) in mice, rats and humans with a focus on the brain uptake was performed. **Subjects & Methods:** Breast cancer tumor-bearing female athymic nude mice (n = 8), and female Sprague-Dawley rats (control, n = 3; ovariectomized, n = 3) were injected intravenously with a dose of 0.1 MBq/g 4FMFES. Twenty-minute PET acquisitions were initiated 1 hour after injection of the radiotracer. Immediately after, low-dose CT was performed in the same bed position. The rat heads were further imaged using T2-weighted proton density MRI to provide anatomical landmarks. PET/CT (and MRI) fusion images were generated and semi-quantitative analysis was conducted to extract %ID/g data. In parallel, 41 breast cancer patients were enrolled in a clinical phase II study to evaluate 4FMFES-PET for oncological assessment, but with the head included in the field-of-view; brain uptake was reported as SUV$_{Max}$. **Results:** Regardless of the species studied, 4FMFES brain uptake was near background levels, except for bilateral foci at the base of the skull, at the midsection of the brain. Anatomical localization of the PET signal using CT (and MRI for rats), indicates that the signal origins from the hypothalamus. Mice uptake in this area reached 2.8 ± 0.6 %ID/g,

a level comparable to ER+ MCF7 tumor xenografts (2.3 ± 1.2 %ID/g). Rat uptake was 0.33 ± 0.03 %ID/g for the control group and significantly higher in the ovariectomized group (0.59 ± 0.12 %ID/g; p < 0.05). Clinical assessment of human hypothalamus uptake yielded a SUV$_{Max}$ score of 0.752 ± 0.227, which is 3-fold higher than the average brain background activity. A non-significant trend toward higher uptake in post-menopausal women (SUV$_{Max}$ = 0.761 ± 0.231, n = 31) was observed compared to the pre-menopausal group (SUV$_{Max}$ = 0.707 ± 0.208, n = 10). **Conclusion:** 4FMFES allowed visualization of ER expression in the hypothalamic region in humans and two different rodent species. Contrary to what was reported previously (Khaytum *et al.*, J Nucl Med 2014;55), ER-targeting tracers accumulates mainly in the hypothalamus, not the pituitary in the brain.

OP-558

Determining the Effects of Age and Gender on Normal Pediatric Brain Metabolism Using FDG-PET

S. Turpin[1], P. J. Martineau[2], M. A. Levasseur[3], R. Lambert[1]; [1]CHU Sainte-Justine, Montreal, QC, CANADA, [2]University of Ottawa, Ottawa, ON, CANADA, [3]CHU Sherbrooke, Sherbrooke, QC, CANADA.

Introduction: Normal databases of brain metabolism can be useful when interpreting an FDG-PET brain study. While normal metabolic activity in the adult brain has been well-studied, much less is known about pediatric brain metabolism. The purpose of our study was to develop mathematical models of metabolic activity of various regions in normal pediatric brains, accounting for both gender and age, using FDG-PET data. **Methods:** 59 FDG-PET/CT brain acquisitions were performed on 59 subjects which varied between 6 months and 18 years of age. These subjects included 30 (50.8%) males. None of these patients had known collagen disease, neuropsychiatric symptoms, epilepsy or CNS neoplasm at the time of the study and none was taking medication that may influence brain uptake. These results were analyzed using commercially available software (Neuro-Q^{TM}), which provided information on the relative metabolism of 47 separate cortical and sub-cortical regions, which were normalized to whole brain activity. For each of these 47 regions, the significance of gender was examined using the Student t-test. Multiple linear and non-linear mathematical models of metabolic activity were developed for each region in order to determine the variation of local metabolism with age. Optimal models of metabolism were selected on the basis of the results of the Akaike Information Criterion (AIC). Mean predicted value and 95% prediction intervals, taking into account age and gender, were derived for all regions. Validation of models was performed analyzing a new set of 16 normal patients. **Results:** The effects of gender were found to be statistically significant only in the posterior cingulate cortex while the relative metabolism of all regions were noted to vary with subject age. For 7 regions, the optimal model was a linear function of age. For the remainder of the regions, the optimal model was non-linear with the best fit provided by a quadratic model in 13, cubic in 6, logarithmic in 11, a power law in 8, and a modified power in 4 regions. In the case of 14 paired regions, the same model could

be used in either hemisphere. Validation demonstrated that values fell within the 95% prediction interval in 95.35% of analyzed regions. **Conclusion:** Pediatric brain metabolism, as studied by FDG-PET, is a complex function of age and, in some cases, gender. This work has provided one of the largest normal pediatric databases to date.

OP-559

Impact of plasma glucose on the pattern of brain FDG uptake and on its performance for prediction of dementia in mild cognitive impairment

I. Apostolova[1], C. Lange[2], P. Suppa[3], S. Klutmann[1], L. Spies[3], M. Grothe[4], R. Buchert[1]; [1]University Medical Center Hamburg-Eppendorf, Hamburg, GERMANY, [2]University Medicine Charite Berlin, Berlin, GERMANY, [3]jung diagnostics GmbH, Hamburg, Hamburg, GERMANY, [4]German Center for Neurodegenerative Diseases, Rostock, GERMANY.

Background: Increased blood glucose level (BGL) has been reported to cause alterations of FDG uptake in the brain that mimic the characteristic pattern in Alzheimer's disease (AD). Aim of the present study was (i) to confirm this finding in well characterized normal control (NC) subjects from the Alzheimer's Disease Neuroimaging Initiative (ADNI), and (ii) to analyze its impact on the prediction of AD dementia (ADD) in mild cognitive impairment (MCI). Methods: The study included all ADNI NCs with baseline FDG PET that were cognitively stable for ≥36 months (n=87, 74.2±5.3y), and all ADNI MCIs with baseline FDG PET, baseline MRI at 3T, and ≥36 months follow-up (n=324, 71.1±7.1y). Seventy-three of the MCIs had converted to ADD within 36 months. PET images were stereotactically normalized to MNI space using SPM8. Brain parenchyma was used as reference region for intensity scaling. In the ADNI NCs, scaled FDG uptake was tested for clusters of correlation with BGL on the family-wise error corrected 5% significance level. In the ADNI MCIs, ROC analysis was used to assess the power of mean FDG uptake in a predefined AD-meta ROI for prediction of ADD after 36 months. ROC analysis was repeated after correcting mean FDG uptake in the AD-meta ROI for BGL based on linear regression in the ADNI NCs. Results: In the ADNI NCs, BGL was 98±16 (59-149) mg/dl. There was a significant cluster of negative correlation between scaled FDG uptake and BGL comprising the precuneus and bilateral parieto-occipital cortex (cluster volume 123ml, p=0.020). The cluster did not include the posterior cingulate. Linear regression of FDG uptake in the AD-meta ROI revealed: FDG uptake = 1.022-0.176*BGL(mg/dl)/1000 (one-sided p=0.059). In the ADNI MCIs, BGL was 101±17 (55-189) mg/dl. Uncorrected FDG uptake in the AD-meta ROI provided an area of 0.784±0.030 under the ROC curve for identification of MCI-to-ADD converters. Correcting FDG uptake in the AD-meta ROI for BGL did not result in significant change of the ROC curve (area=0.786±0.030). Conclusions: These findings confirm that increasing blood glucose is associated with relative reduction of FDG uptake in the cortex (compared to white matter) even in the 'acceptable' range BGL<150mg/dl. BGL-associated pattern is similar to the typical AD-pattern, but it is not identi-

cal: the pattern comprises the precuneus (more than posterior cingulate) and parieto-occipital (rather than parieto-temporal) cortex. BGL-associated variability of FDG uptake has no relevant impact on the power of FDG PET for prediction of MCI-to-ADD conversion.

OP-560

Using EQ·PET to reduce reconstruction-dependent variation in FDG PET brain imaging

M. Vanhoutte[1], R. Lopes[2], G. Petyt[3], C. Hossein-Foucher[4], A. Aziz[3], A. Jaillard[5], H. Lahousse[3], F. Semah[4], R. Fahmi[6]; [1]Siemens Healthineers / Univ. Lille, Inserm U1171, CHU Lille, F-59000 Lille, France, Lille, FRANCE, [2]Univ. Lille, Inserm U1171, CHU Lille / CHU Lille, Department of Neuroradiology, Lille, FRANCE, [3]CHU Lille, Department of Nuclear Medicine, Lille, FRANCE, [4]Univ. Lille, Inserm U1171, CHU Lille / CHU Lille, Department of Nuclear Medicine, Lille, FRANCE, [5]Univ. Lille, Inserm U1171, CHU Lille, Lille, FRANCE, [6]Siemens Healthineers, Molecular Imaging, Knoxville, TN, UNITED STATES OF AMERICA.

Aim: FDG-PET imaging is routinely used in Alzheimer's disease (AD) diagnosis, thanks to the relationship between FDG uptake and brain function. We used EQ·PET, a proprietary standardization tool based on NEMA phantom and well validated in oncology (M. Kelly, et al EJNMMI'2011, E. Quak et al., EJNMMI'2015), for reducing the quantitative variation resulting from differences in reconstruction protocols and hence allow a meaningful group analysis of longitudinal brain FDG images of AD patients. **Materials & Methods**: NEMA IQ phantom was filled with FDG according to EARL recommendations, and scanned on a Siemens mCT-Flow scanner following EANM guidelines. Images were reconstructed using two reconstruction methods: (R1) 3D-OSEM with TOF, 2 iterations and 21 subsets; and (R2) 3D-OSEM with TOF, 6 iterations and 21 subsets. EQ·PET was then used to align the recovery coefficients curves (CC) of reconstructions (R1) and (R2) with the EARL standard CC and then deduce the optimal Gaussian filter to be applied to (R2) to align it with (R1). The reduction in variability between the two reconstructions with EQ·PET was assessed on brain FDG-PET scans of nine patients with early-onset AD. We used Sum of Squared Differences (SSD) to quantify the differences between corresponding pairs of images before and after EQ·PET alignment. Three values were calculated and compared: (1) 3D spatial resolution using AFNI software (https://afni.nimh.nih.gov/), (2) regional mean SUVs, and (3) native PET voxel-wise intensities inside a brain mask. Note that for (2), calculations were performed within 116 Automated Anatomical Labeling (AAL) regions of interest in the MNI space after registering all images to a common MNI FDG template. This was achieved with Scenium software (Siemens Healthineers). To eliminate the effects of spatial registration in these cases, the same geometric transformation was applied to both reconstructions for all patients. Paired t-tests were used to compare results before and after data alignment with EQ·PET. **Results**: The optimal filter size resulting from EQ·PET experiments was FWHM=3.1mm. Averaged SSDs before (resp. after) EQ·PET alignment were: (1) 3D spatial resolution: 1.9mm³ (resp.

0.5mm³; p=1.3e-07); (2) mean regional SUVs: 0.41 (resp. 0.3; p=1.0e-06); and (3) normalized voxel-wise brain intensity: 0.74 (resp. 0.38; p=3.9e-11). **Conclusion**: EQ.PET significantly reduces reconstruction-dependent variation in brain FDG-PET measurements, enabling increased confidence in quantitative comparison of clinical images for monitoring treatment response and/or disease progression. EQ·PET could be similarly applied to reduce inter-scanner variability. Our results show the potential of using EQ·PET in Neurology applications.

OP-561

Calculation of image-derived input function for absolute quantification of clinical [18]FDG PET/MRI studies of the brain

I. Shiyam Sundar[1], O. Muzik[2], L. Rischka[1], A. Hahn[1], I. Rausch[1], R. Lanzenberger[1], M. Hienert[1], E. Maria Klebermass[1], T. Traub-Weidinger[1], T. Beyer[1]; [1]Medical University Vienna, Vienna, AUSTRIA, [2]Wayne State University School of Medicine, Detroit, MI, UNITED STATES OF AMERICA.

Aim: Absolute quantification of PET brain studies requires the knowledge of an arterial input function (IF), usually obtained invasively via arterial cannulation. Here we present a non-invasive method that allows determination of the image-derived IF (IDIF) from [18F]FDG-PET/MRI brain data. **Subjects and Methods:** As a part of an ongoing study, six subjects underwent dynamic FDG test-retest PET/MRI examinations in a fully-integrated PET/MRI system (Siemens, Biograph mMR). The protocol included a time-of-flight MR angiography (TOF-MRA) sequence used to extract an internal carotid artery mask (ICAM) as well as sparsely sampled MR-navigators for motion correction. The PET data was reconstructed using the OSEM algorithm that included both a scatter and a CT-based brain attenuation correction. Arterial blood samples (AIF) were collected as the gold standard. Calculation of the IDIF was performed in 3 steps: (1) automatic segmentation of the petrous region from the ICAM, (2) determination of activity in the PET background region surrounding the ICAM using TOF geometric information and the scanner's point spread function (PSF) and (3) performing a spill-in correction in the target region by subtracting the contribution from the background, and a spill-out correction using the recovery coefficients obtained from the ICAM and PSF. The ratio (R) of the area-under-the-curve (AUC) of the IDIF to the AUC of AIF was used as a similarity measure between the two IFs. Finally, parametric images representing cerebral metabolic rate of glucose (CMRGlc) were calculated using the standard rate constant approach. **Results:** Our results indicate a 3±7% difference for R (0.97 ± 0.07), with IDIF underestimating the true IF (AIF) due to overcorrection at later time points. Overall, regional CMRGlc values in 83 brain regions were overestimated by 3±9%. **Conclusion:** Our results indicate that using an integrated PET/MR protocol, the CMRGlc can be non-invasively determined from image data with less than 10% overestimation compared to arterial sampling. As such, this methodology appears to be well suited for assessment of CMRGlc in clinical routine.

Do.MoRe: Thyroid Cancer - Clinical

OP-562

18FDopa PET/CT is more sensitive than WB-MRI for the detection of structural disease in medullary thyroid cancer with increased calcitonin.

M. Terroir, I. Borget, C. Caramella, K. El Farsaoui, D. Deandreis, S. Grimaldi, J. Lumbroso, A. Berdelou, E. Baudin, M. Schlumberger, S. Leboulleux; Gustave Roussy, Villejuif, FRANCE.

Aim: Patients with medullary thyroid carcinoma (MTC) frequently present recurrent or persistent disease after initial surgery that is usually detected by an increased serum calcitonin (Ctn) level. The clinical challenge is to localize the disease in the neck when surgery can cure the patients, and in distant sites. The diagnostic value of 18FDopa (fluorodihydroxyphenylalanin) in MTC patients has not yet been compared to a complete imaging work-up. The aim of our study was to compare 18FDopa PET/CT and WB MRI (whole body magnetic resonance imaging) to 18FDG (fluorodeoxyglucose) PET/CT, whole body CT scan, neck US and bone scintigraphy in MTC patients with increased Ctn levels and no known distant metastases to determine the most effective imaging modality to localize the recurrent/persistent disease. **Material and Methods:** Data of 36 consecutive MTC patients with increased Ctn and no known distant metastases were prospectively recorded between September 2014 and 2016. We compared the blind interpretation of each imaging modality to the reference assessment for structural disease defined as pathology when available or agreement between two imaging modality or subsequent follow up. The detection rate of each imaging modality was determined in a per patient, per organ and per lesion analysis. **Results:** Thirty six patients (21 females, mean age 57 years) were enrolled. The median serum Ctn level was 760 pg/ml (range 21-10121) and the median Ctn doubling time was 1.5 years (range 0.4-20.7). The reference assessment demonstrated structural disease in 23 patients (64%), for a total of 65 lesions in 37 organs (9 in the thyroid bed, 15 in the neck lymph nodes, 6 in mediastinal lymph nodes, 1 in the lungs, 2 in the liver, 3 in bones and 1 in another site). At a patient level, the detection rates were 64% for 18FDopa, 40% for 18FDG, 40% for WB-MRI, 48% for CTscan. There was no correlation neither with Ctn doubling time nor with Ctn level. The per lesion detection rates were 95% for18FDopa, 52% for 18FDG, 27% for WB-MRI, 33% for CTscan. Neck US detected 58% of the neck lesions. **Conclusion:** These results suggest that 18FDopa PET/CT is more sensitive than any other imaging modality including WB MRI to detect structural disease in MTC patients with increased calcitonin and no known distant metastases.

OP-563

Role of 68Ga-DOTA RGD PET/CT in patients with TENIS (Thyroglobulin elevation with negative Iodine scintigraphy) syndrome and its comparison with 18 F FDG PET/CT

A. S. Parihar, R. Basher, J. Shukla, R. Vatsa, A. Sood, A. Bhattacharya, B. R. Mittal; Post Graduate Institute of Medical Education & Research, Chandigarh, INDIA.

Purpose: To evaluate the role of 68Ga-DOTA RGD PET/CT in patients with TENIS (Thyroglobulin elevation with negative Iodine scintigraphy) syndrome and its comparison with ^{18}F-FDG PET/CT. **Materials and Methods:** As a pilot study, 10 patients (3 Males, 7 Females) with mean age of 44.2 years (range from 16-67 years) with TENIS syndrome suggested by rising levels of Thyroglobulin (Stimulated Tg>2 ng/mL) who had undergone ^{18}F-FDG PET/CT were selected for the study. All the patients had undergone total thyroidectomy (8 papillary Ca thyroid; 2 follicular Ca thyroid) and post-surgery ^{131}I ablation therapy. On follow up, they had rising Tg levels (mean 148.8 ng/mL ; range of 85-281 ng/mL) with negative ^{131}I whole body diagnostic scintigraphy. These patients subsequently underwent ^{18}F-FDG PET/CT for disease evaluation followed by ^{68}Ga-DOTA RGD PET/CT. Quantification analysis and comparison of detected lesions in these two modalities was done using standard uptake values (SUVmax). **Result:** Of the 10 patients, two did not have any abnormal uptake of tracer on ^{18}F-FDG PET/CT. Both these patients showed uptake of ^{68}Ga-DOTA RGD in the thyroid remnant tissue or at the metastatic sites. Of the eight patients having positive FDG PET scan findings, two had additional metastatic sites (cervical lymph nodes, lung nodules) on ^{68}Ga-DOTA RGD PET/CT. Three patients had detection of the same lesions on both the diagnostic modalities, whereas in the remaining three patients ^{18}F-FDG PET/CT detected more number of lesions compared to ^{68}Ga-DOTA RGD PET/CT. The mean SUVmax of the metastatic cervical lymph nodes detected on ^{18}F-FDG PET/CT was 6.34 (range 2.5-15), that of the lung nodules was 4.5 (range 2-6) with mean blood pool SUVmax of 2.5. On ^{68}Ga-DOTA RGD PET/CT, the mean SUVmax of the cervical lymph nodes was 4.8 (range 2.5-8), that of the lung nodules was 3.2 (range 2-5) with mean blood pool SUVmax of 0.9. Remnant thyroid bed tissue was detected on ^{68}Ga-DOTA RGD PET/CT with SUVmax of 4.0 and metastatic cervical lymph nodes with SUVmax 2.5 that were negative on ^{18}F-FDG PET/CT. **Conclusion:** The use of ^{68}Ga-DOTA RGD, an angiogenesis marker targeting integrin $\alpha_v\beta_3$, in patients with TENIS syndrome can be a useful modality as an adjunct to ^{18}F-FDG PET/CT for detection of additional lesions as well as for evaluating disease activity in FDG negative cases. If ^{68}Ga-DOTA RGD PET/CT results are encouraging from multicentric studies, the FDG negative and RGD positive TENIS patients may be potential candidates for ^{177}Lu RGD therapy

OP-564

Comparison of F-18 DOPA and Ga-68 DOTA TATE in detection of recurrences or metastasis of medullary thyroid cancer

S. Asa[1], K. Sönmezoğlu[1], E. Kaymak Akgun[1], S. Razavi Khosroshah[1], S. Toksöz[2], H. Pehlivanoğlu[1], E. Karayel[1], M. Ocak[3], L. Kabasakal[1], Y. Bükey[2]; [1]Istanbul University Cerrahpasa Medical Faculty Department of Nuclear Medicine, Istanbul, TURKEY, [2]Istanbul University Cerrahpasa Medical Faculty Department of General Surgery, Istanbul, TURKEY, [3]Istanbul University Pharmacy Faculty, Istanbul, TURKEY.

Aim: The aim of this retrospective study was to compare F-18 DOPA PET/CT (FDOPA) and Ga-68 DOTA TATE PET/CT (TATE) in detection of recurrences or metastasis of medullary thyroid cancer (MTC) patients with elevated calcitonin levels during follow-up period after initial treatment. **Methods:** A total of 32 patients with high serum calcitonin levels during follow-up were enrolled in this study. All patients underwent FDOPA and TATE scans, which were performed within interval of 38 (2-120) days. PET/CT analysis was done based on per-patient basis and per-lesion basis (maximum 10 lesion/patient). Lesions with increased radiopharmaceutical uptake were examined within six categories as local, nodal (cervical, mediastinal, other), hepatic, skeletal, lung and brain. Detection rates of metastatic lesions were assessed for both FDOPA and TATE. **Results:** The study group included 19 (59,3%) females and 13 (40,6%) males with a mean age of 51,3 years. The mean calcitonin level was 1908,7 ng/L (range: 62,4-14000 ng/L). On the patient-based analysis, we observed at least one focus of abnormal uptake in 24 of 32 patients using both F-18 DOPA and Ga-68 DOTA TATE scans with a mean of calcitonin levels 2471,2 ng/L (range:125-14000 ng/L). Eight of 32 patients who had lower calcitonin levels (mean calcitonin:221,1; range: 62,4-573) did not have any pathological uptake in both imaging modalities. The difference of calcitonin level between two groups was statistically significant (T test; $p < 0.05$). There were 5 patients with FDOPA positive scan despite of negative TATE. On the other hand, in two patient, TATE was positive versus negative FDOPA scan. On the lesion-based analysis, 79 lesions were detected with FDOPA and 83 lesions with TATE scans. While 17 lesions(1 of local, 7 of servical, 3 of mediastinal, 1 of other nodal, 2 of hepatic and 1 of brain) were positive in F-18 DOPA, but negative in TATE. However, there were 21 lesions (1 of local, 7 of servical, 2 of hepatic and 11 of bone) with positive TATE scan positive, but negative on FDOPA imaging. **Conclusion:** Both F-18 DOPA PET/CT and Ga-68 DOTA-TATE PET/CT scans have clinical impact on the management of patients with MTC, according to our results. However, FDOPA imaging seems more effective modality overall on the patient-based evaluation whereas DOTA-TATE scanning is clearly better in detection of bone lesions Acknowledgements: This study was supported by Istanbul University Scientific Research Projects with project no:35236

OP-565

Characteristics of malignant thyroid lesions on [18F] Fluorodeoxyglucose (FDG) Positron Emission Tomography (PET)/Computed Tomography (CT)

H. Nasr[1,2], H. Farghaly[1,3], A. Alqarni[1], S. Al-Salem[1]; [1]Radiology Departement, Prince Sultan Military Medical City, Riyadh, SAUDI ARABIA, [2]Nuclear Medicine Unit, Kasr Al-Aini Cairo University Hospital, Cairo, EGYPT, [3]Nuclear Medicine Unit, Assuit University Hospital, Assuit, EGYPT.

Objectives: To determine the variables that can best differentiate malignant from benign thyroid lesions incidentally found on ^{18}F-FDG PET/CT. **Methods:** All ^{18}F-FDG PET/CT studies starting from 2011 to end of 2016 were reviewed for incidental thyroid lesions or metabolic abnormalities. Only patients found to have FNAB or histopathology were included. Patients with known thyroid malignancy were excluded. Patients were analyzed for age, sex, SUVmax, non-enhanced CT tissue density in

mean Hounsfield units (HU), uptake pattern (focal or diffuse) and gland morphology (MNG or diffuse). A control group of 15 patients with normal thyroid glands was used to assess tissue density (HU) for normal thyroid tissue. Pearson Chi-squar test was used to compare categorical variables, unpaired T-test and one-way ANOVA to compare means of continuous variables and ROC analysis to assess the best cut off points for SUVmax and HU. Logistic regression was used to determine the independent predictors for malignant lesions. **Results:** Thyroid abnormalities were detected in 134 patients. Histopathology could be retrieved for 48/134 patients (36%). Biopsy was unsatisfactory/indeterminate in 4/48 patients (8%). Final analysis included only 44 patients (age 55.2±14.7; 30 females (68%)) with unequivocal FNAB or histopathology. MNG was noted in 17/44 patients (38.6%). Thyroid malignancy was found in 16/44 (36.4%). Thyroid malignancies were 12 papillary, 1 follicular, 1 Hurthle cell and 2 lymphoma. Benign lesions were 21 follicular adenomas, 2 colloid nodules and 5 autoimmune thyroiditis. Focal FDG uptake was more frequently associated with malignant lesions compared to benign lesions (75% vs. 43%; *p*=0.039). The mean SUVmax and tissue density (HU) were higher in malignant than benign lesions (8.8±8.3 vs. 3.6±1.9, *p*=0.024) and (48.9±12.7 vs. 32.9±17.5, *p*=0.003) respectively. Mean HU in the control group with normal thyroid tissue was 90±7.4, significantly higher than both benign and malignant lesions (*p*<0.001). Cutoff points to best differentiate malignant from benign lesions were SUVmax >4.7 and HU >42. Sensitivity, specificity, PPV, NPV and accuracy to detect malignancy for SUVmax>4.7 were 68.8%, 78.6%, 64.8%, 81.5 & 75.0% (*p*=0.002), for HU>42 were 81.3.0%, 75.0%, 65.0%, 87.5 & 77.3% (*p*=0.0003) and for both parameters combined were 87.5%, 60.7%, 56.0%, 89.5% and 70.5% (*p*=0.002) respectively. Only HU>42 and SUVmax>4.7 were independent predictors for malignancy with odd ratios 8.98 and 4.93 respectively. **Conclusion:** Higher tissue density (HU>42) and FDG uptake (SUVmax>4.7) as well as tendency for focal uptake pattern are characteristics highly predictive of malignancy when associated with incidentally detected thyroid lesions on ^{18}F-FDG PET/CT.

OP-566

FDG+/RAI+ patients with distant metastases from differentiated thyroid cancer can benefit from RAI treatment

l. Males[1], S. Grimaldi[2], M. Terroir[3], J. Lumbroso[1], D. Deandreis[1], A. Berdelou[1], E. Baudin[1], M. Schlumberger[1], S. Leboulleux[1]; [1]Institut Gustave Roussy, Villejuif, FRANCE, [2]Serena Grimaldi, villejuif, FRANCE, [3]Marie Terroir Cassou de Mouna, Villejuif, FRANCE.

Purpose: Patients with distant metastases from differentiated thyroid cancer (DTC) with FDG uptake have the same survival rate whether they present or not radioactive iodine (RAI) uptake, suggesting that FDG could indicate resistance to RAI treatment. The purpose of this retrospective monocentric study was to evaluate tumor response rate following RAI treatment in DTC patients with distant metastases that present both FDG and RAI uptakes (FDG+/RAI+). **Method:** Thirty two FDG+/RAI+ DTC patients with distant metastases were included with following criteria i) DTC confirmed by our pathologist (ii) first RAI admin-istration between January 2007 and December 2016 (iii) distant metastases known prior to RAI administration or diagnosed on the post-therapeutic WBS iv) FDG-PET performed within 6 months of the first post-therapeutic WBS v) at least one lesion with RAI uptake and one lesion with FDG uptake vi) follow up of at least 3 months vii) availability of morphological CT examina-tion 6 months after each RAI administration. **Results:** Thirty two patients, (16 females, mean age: 60 years) treated with RAI (100 mCi following thyroid hormone withdrawal every 6 months for 2 years and annually afterwards in case of RAI efficacy). The best scintigraphic response evaluated on post-therapeutic WBS was a complete response (CR) in 1 (3%) case, a partial response (PR) in 26 (82 %). The best PERCIST response evaluated on FDG PET was a CR in 5 (15%) cases, a PR in 14 (44%) cases. The best RECIST response among 19 patients with target lesions was PR in 10 (53 %) cases and SD in 9 (47 %) cases. Thyrogobulin serum levels de-creased by more than 50% in 21 (66%) cases. The mean number of RAI administration to obtain the best response ranged from 1.7 to 2.1 depending on the method used for tumor evaluation. The mean duration of response ranged from 25 to 31 months depending on the method used for tumor evaluation. After a mean follow up of 4.4 years after the diagnostic of distant me-tastases, 7 (16%) patients died and 25 (78%) are still alive with disease (9 undergoing repeated RAI treatments, 12 (38%) under follow-up without treatment and 4 (12%) under tyrosine kinase inhibitors. **Conclusions:** FDG+/RAI patients are not cured with RAI but can benefit from RAI administration. Patients should not be excluded from RAI treatment based on FDG uptake.

OP-567

Underestimation of the risk of metastatic disease in differentiated thyroid cancer adopting the 2015 ATA guidelines

D. Albano, M. Gazzilli, M. Bonacina, R. Durmo, E. Cerudelli, M. Panarotto, F. Bertagna, R. Giubbini; Spedali Civili Brescia, Brescia, ITALY.

Aim: according to the 2015 American Thyroid Association (ATA) management guidelines, thyroid ablation by radioactive iodine therapy (RAIT), is recommended only in patients with high risk differentiated thyroid cancer (DTC) (patients with distant metas-tases or T4 stage according to AJCC 2010 classification). Meta-static disease is often not recognized at the time of diagnosis and it can be silent for a long time interval. Patients with dis-tant metastases, especially bone metastases, show poor clinical outcomes. An early diagnosis is therefore crucial, allowing an early RAIT, which can be decisive in a significant percentage of patients. Adopting the recent 2015 ATA guidelines, there is the risk of underestimating the presence of metastases in several patients. Aim of the present study was to retrospectively analyze in a consecutive cohort of patients evaluated in our institute the prevalence of metastatic disease after surgery, before or after RAIT and to evaluated the influence of the new ATA guidelines in the diagnostic work-up and/or treatment. **Materials and Methods**: between March 2010 and March 2017, 2018 patients underwent RAI ablation of residual thyroid remnant after total

or near total thyroidectomy. In 61 patients (46 female, 15 male; average age: 60 years) distant metastases were detected. In 29 patients the metastases were in the lungs, in 21 in the bones and in 11 in more than one organ, respectively. All metastases were confirmed by histology and/or other imaging modalities. **Results**: in 15/61 (25%) patients metastases were detected before RAIT, while in 46/61 (75%) were discovered after RAIT. Comparing patient with metastases detected before and after RAI, no differences were demonstrated considering age, sex, histotype, multifocality of primary cancer and metastatic localization. Metastatic DTC discovered before RAIT had higher Thyroglobulin level before ablation and received a higher RAI total activity and number of treatments. Before RAIT only 22/61 patients were categorized at high risk according to 2015 ATA guidelines, 14 at low risk and 25 at intermediate risk, respectively. Among patients with intermediate risk, only 2 presented adverse features (lymph nodes outside the central neck compartment and/or advanced age) which indicated RAI therapy; whereas in 23/25 RAI ablation of thyroid remnant would not have been recommended. **Conclusions**: following the recent ATA guidelines 61% of patients with metastatic DTC would not have been treated with RAIT, with the risk of late diagnosis and treatment.

OP-568

30 mCi Radioiodine Treatment of Thyroid Carcinoma Patients in the post ESTIMABL Era

D. Rusu[1], V. Fleury[1], C. Palpacuer[2], M. Le Thiec[1], M. Colombié[1], F. Kraeber-Bodéré[1,3,4], C. Rousseau[1,4]; [1]Nuclear Medicine, ICO Cancer Fighting Center -, SAINT HERBLAIN, FRANCE, [2]Statistics Unit, ICO Cancer Fighting Center -, SAINT HERBLAIN, FRANCE, [3]Nuclear Medicine, University Hospital, Nantes, FRANCE, [4]CRCNA, Inserm U892, CNRS UMR 6299, Nantes, FRANCE.

Aim: To investigate the effectiveness of 30 mCi ^{131}I treatment of low risk thyroid cancer patients. It has been suggested that ablation might not be as complete as with higher doses. **Methods**: 103 patients were included in this retrospective study. They were treated in our department from October 2012 until August 2016 with 30 mCi ^{131}I post total thyroidectomy and had a documented assessment of treatment response (Thyrogen stimulated Thyroglobuline and neck ultrasonography). The patients were included in the four ATA response groups. The excellent response group was subdivided in one group with detectable and one with undetectable Tg. The patient characteristics were compared according to treatment response using Chi-square test or Fisher's exact test for qualitative variables and Student's t-test or Wilcoxon's test for quantitative variables. **Results**: 82 females and 21 males with median age of 48.8 +/-14 were treated. They had mostly papillary (40.8%) or vesicular variant of papillary cancer (52.4%). 24.4% were pT1am lesions and 57.3% pT1b, 43.7% pN0, 51.5% pNx and 4.9% pN1. 38.6% of the carcinomas were fortuitously discovered. The qualitatively evaluation of scintigraphy found un absent or faint uptake in 19,6% of cases, moderate or intense in 75.5% and very intense in 4.9% pts. The median Tg during the treatment was 3, IQR : 0,3-7.7 (25.2% < 0.3; 23.3% ≥ 0.3 and < 2.5; 25.2% 2.5-7.5). The anti-Tg antibodies

were present in 11.8% pts. After at least 6 months, the stimulated Tg was < 1ng/ml in 91.3% cases, (58.3% undetectable and 33% detectable). The anti-Tg antibodies were positives in 3.1% of pts. The ultrasonography was negative in 82.5% pts and abnormal in 17,5% pts (11,65% had thyroid bed images). The ATA response was excellent in 78 pts (53 with undetectable Tg and 25 detectable), biochemically incomplete in 3, structurally incomplete in 1 and indeterminate in 21 pts. None of the analyzed variables was predictable of ATA excellent response versus other responses. By comparing the two subgroups of ATA excellent response group, the only variable predicting the detectability of Tg after treatment was the Tg during treatment. Two patients had additional surgeries (one with additional ^{131}I treatments) and three had additional radioiodine treatment. **Conclusion**: Although the excellent ATA response was the general rule post 30 mCi radioiodine treatment in our study, a quarter of patients had not that response, needing continuing observation. A third of the excellent ATA response group patients had detectable stimulated Thyroglobuline.

OP-569

Usefulness of I-123-Dx-Whole-Body Scan in planning 131I-treatment of the differentiated thyroid carcinoma in children and adolescence

M. F. Villani, A. Grossi, B. Cassano, M. Pizzoferro, G. Ubertini, S. Chiapparelli, M. C. Garganese; Bambino Gesu' Children's Hospital, Rome, ITALY.

Background: early radioiodine treatment of differentiated thyroid carcinoma (DTC) is important to avoid disease progression. Furthermore, in paediatric DTC patients, the necessity to be curative on metastatic disease is urgent, as well as the attention to minimize the risks. For these reasons, a diagnostic scan may be useful to asses therapeutic tailored activity. This is not a routine practice and many Centers are used to administer fixed doses of 131I, considering thyroglobulin levels and tumour staging. **Aim:** to evaluate the usefulness of diagnostic 123I-WBS (123I-Dx-WBS) in combination with rh-TSH, in planning radioiodine treatment in paediatric DTC. **Materials and Methods**: 101 123I-Dx-WBS of 55 patients (21 M, mean age 15 years, range 5-18 years) followed at the Bambino Gesù Pediatric Hospital for differentiated thyroid cancer from February 2004 to December 2016 were retrospectively evaluated. In 41 out of 55 patients (20 M and 21 F, mean age 14 years, range 5-18 years, 123I-Dx-WBS was performed after administration of rh-TSH (Thyrogen®) for completion of staging before radioiodine treatment with 131I. Histological examination revealed a papillary carcinoma in 37/41 (90%) patients (classic variant in 26/37-70.3%-,follicular variant 3/37-8.1%-, aggressive histological types in 7/37-18.9%-, Warthin-like in 1/37-2.7%), follicular in the other 4(10%). All patients received Thyrogen ®, 0.9 mg daily for two consecutive days (Day 1 and 2), and 123I-NaI 24 h later (Day 3); 123I-Dx-WBS was performed on Day 4. TSH levels were evaluated at baseline and on Day 3, Thyroglobulin (Tg) at baseline and on Day 5. Statistical analysis was performed. **Results**: in 41/41 (100%) cases optimal stimulation is obtained (TSH > 30 mIU / L). Mean Tg value on Day 5 was 28.49 (range

<0.2 to 300). ROC curve analysis showed that Tg is not a good predictor for staging modification (AUC=0.6855). 123I-Dx-WBS showed both remnant and lymph node in 11/41 (27%), lymph node localization alone in 1/41 (2.5%), lung alone in 1/41 (2.5%), both lymph node and lungs in 2/41 (5%), thyroid remnant alone in 26/41 (63%) patients. 123I-Dx-WBS modified patients staging in 12/41 (29%): in 3/12 (25%) for the presence of lung metastases and in 9/12 (75%) for lymph node involvement. In all these patients, administered activity of radioiodine for radionuclide therapy was then modified. **Conclusions:** Although further studies are needed, our data showed that the combined use of rh-TSH and 123I-Dx-WBS allows to obtain an accurate and complete staging of disease, in order to take the best therapeutic strategies.

Peptide receptor radionuclide therapy (PRRT) in ENETS Grade 3 (G3) Neuroendocrine Neoplasia (NEN) - a single-institution retrospective analysis

S. Thang[1,2], M. Lung[1], G. Kong[1], M. Hofman[1], J. Callahan[1], M. Michael[1], R. Hicks[1]; [1]Peter MacCallum Cancer Centre, Melbourne, AUSTRALIA, [2]Singapore General Hospital, Singapore, SINGAPORE.

Aims: Grade 3 NENs are aggressive tumours with poor prognosis but increasingly recognised to have well- and poorly-differentiated subgroups. Although generally responsive to chemotherapy, durability of response is poor. PRRT+/- radiosensitising

chemotherapy is a potential treatment for disease with high SSTR-expression without spatially discordant FDG-avid disease. We retrospectively evaluated the efficacy of PRRT in G3 NEN. **Methods:** Kaplan-Meier estimate was used to determine overall survival (OS) and progression-free survival (PFS), defined from start of PRRT. Subgroup-analysis was performed for patients with Ki-67≤55% and >55%. The proportions of patients treated with PRRT who achieved anatomical (N=24) and molecular imaging (SSTR imaging, N=24; FDG PET/CT, N=19) 3 months after induction PRRT were determined. Toxicity profile of PRRT was evaluated. **Results:** 29 consecutive patients (M=17; age 16-78 y.o; Ki-67≤55%=23) were reviewed. 18 patients had pancreatic , 5 small bowel, 3 large bowel, 2 bronchial and 1 unknown primary disease. Most (26/29) had significant FDG-avid disease (i.e. intensity above liver parenchyma) prior to treatment. Patients received median 4 cycles of induction PRRT (range 1-5). 21 had radiosensitising chemotherapy. Most had ^{177}Lu-DOTA-octreotate with median cumulative activity of 25.5 GBq. 90% were treated for disease progression, with 76% receiving at least one line of prior chemotherapy. 12 patients received subsequent maintenance cycles of PRRT due to recrudescent disease after response. Median follow-up was 32 months. On RECIST 1.1, the disease control rate (DCR) at 3 months was 76%; 38% (9/24) PR and 38% SD. On SSTR imaging DCR was 62%; 58% (14/24) PR and 4% (1/24) SD. On FDG PET imaging, 11% (2/19) had CMR and 37% (7/19) had PMR. Of note, 5 patients (all Ki-67≤55%) showed further imaging response up to 15 months post induction cycles of PRRT. The median PFS from start of PRRT was 9.3 months: for Ki-67≤55%, 14 months; and Ki-67>55%, 4 months. There were 17 deaths (Ki-67≤55%, 12 deaths; Ki-67>55%, 5 deaths), with median OS of 21 months: for Ki-67≤55%, 41 months; and Ki-67>55%, 7 months. Grade 3 and 4 lymphopenia and thrombocytopenia occurred in five and six patients, respectively. No renal or liver toxicity related to treatment was seen. **Conclusions:** Although proliferation rate remains an important predictor of survival in G3 NEN, PRRT achieves clinically- relevant disease control with acceptable toxicity even in patients who have already failed first-line chemotherapy.

OP-582

The HSP90-inhibitor Onalespib Potentiates ^{177}Lu-Dotatate Treatment of Neuroendocrine Tumors

S. Lundsten, A. Mortensen, A. Mäkiniemi, D. Spiegelberg, B. Stenerlöw, M. Nestor; Department of Immunology, Genetics and Pathology, Uppsala University, UPPSALA, SWEDEN.

Introduction: The HSP90-inhibitor Onalespib is in clinical trials for therapy of various tumor types. Preclinical studies have shown that Onalespib can function as a radiosensitizer in squamous cell carcinoma and adenocarcinoma in combination with external radiation. However, no studies have investigated the potential for Onalespib to enhance effects of targeted radionuclide therapy. ^{177}Lu-[DOTA^0,Tyr^3]octreotate (DOTATATE) is currently used in clinical trials for treatment of patients with neuroendocrine tumors with promising results. Thus, the aim of the study was to investigate whether Onalespib potentiates

the therapeutic effect of ^{177}Lu-DOTATATE *in vitro*. **Material & Methods:** Dose dependent effects of Onalespib were first assessed using cell viability assays in a panel of neuroendocrine cancer cell lines. Cellular uptake and binding specificity studies of ^{177}Lu-DOTATATE was then evaluated. Potential effects of Onalespib on somatostatin receptor density were assessed using Western blot. Finally, an *in vitro* 3D tumor spheroid model was used to evaluate the therapeutic effects of ^{177}Lu-DOTATATE, Onalespib, and the combination of the two. **Results:** The majority of the investigated cell lines responded to Onalespib treatment and demonstrated specific uptake of ^{177}Lu-DOTATATE. Western blot assays indicated that the expression of somatostatin receptors was not affected by treatment with Onalespib. The 3D tumor spheroid assays demonstrated clear benefits of a combination treatment. Two weeks after treatment start, fractionated therapy, using either Onalespib or ^{177}Lu-DOTATATE, reduced spheroid growth rate resulting in spheroid sizes of approximately 50% of untreated controls. However, spheroids treated with the combination had not even resumed growth at this time. **Conclusions:** By combining treatments of Onalespib and ^{177}Lu-DOTATATE in patients with neuroendocrine cancer, therapeutic effects may be improved. This could potentially lead to lower radiation doses and reduced side effects. Continued studies *in vivo* to further assess therapeutic effects and potential toxicity is warranted.

OP-583

Heterogeneity derived by somatostatin receptor PET Predicts Overall Survival in G1/2 Pancreatic NET Patients Envisaged for Endoradiotherapy

R. A. Werner[1], H. Illhan[2], M. Mooz[1], S. Lehner[2], L. Papp[3], N. Zsótér[4], I. Schatka[5], D. O. Mügge[1], T. Higuchi[1], A. K. Buck[1], P. Bartenstein[2], F. Bengel[6], M. Essler[7], C. Lapa[1], R. A. Bundschuh[7]; [1]Department of Nuclear Medicine, Universitätsklinikum Würzburg, Würzburg, GERMANY, [2]Department of Nuclear Medicine, Ludwig-Maximilians-University Munich, Munich, GERMANY, [3]Department of Nuclear Medicine, Medical University of Vienna, Vienna, AUSTRIA, [4]Mediso Medical Imaging Systems Ltd., Budapest, HUNGARY, [5]Department of Nuclear Medicine, Charité - Universitätsmedizin Berlin, Berlin, GERMANY, [6]Department of Nuclear Medicine, Hannover Medical School, Hannover, GERMANY, [7]Department of Nuclear Medicine, University Medical Center Bonn, Bonn, GERMANY.

Introduction: Neuroendocrine tumors of pancreatic origin (pNET) are a rare, but aggressive tumor entity. Early identification of rapid tumor progression could improve decision-support in patients envisaged for endoradiotherapy (ERT). We aimed to elucidate the potential of intratumoral heterogeneity determined by baseline somatostatin receptor (SSTR)-PET/CT before ERT. **Subjects and Methods**: 31 patients suffering from G1/G2 pNET were enrolled (14 females, 60 ±10 years, n=23/31 G2). Before ERT with ^{177}Lu-labeled somatostatin analogs, baseline SSTR-PET/CT was performed. After manual segmentation of 162 (median per patient, 5) metastases, intratumoral textural features were computed. The impact of conventional PET parameters (mean/maximum standardized uptake value, SUV$_{mean/}$

$_{max}$), imaging-based heterogeneity features as well as clinical parameters (e.g. Ki67, prior therapy, Chromogranin A) for prediction of both progression-free (PFS) and overall survival (OS) was evaluated. **Results**: Within follow-up of median 4.4y, tumor progression was detected after a median of 1.5y in 21 patients; 13/31 deceased after a median of 1.9y. The parameter Entropy, reflecting derangement on a voxel-by-voxel analysis, predicted OS as proven by Cox analysis (p=0.03, PFS, p>0.05). In subsequent ROC analysis, its predictive ability for OS was supported (cutoff=6.7, AUC=0.71, p=0.02). Increasing Entropy could predict a longer survival (>6.7, OS=2.5y, 17/31), whereas less voxel-based derangement portended inferior outcome (<6.7, OS=1.9y, 14/31). Besides, these findings were supported in a G2 subanalysis (>6.9, OS=2.8y, 9/23 vs. <6.9, OS=1.9y, 14/23). None of the heterogeneity features correlated significantly with Ki67. Investigating clinical and conventional PET parameters, the proliferation index holds the potential of PFS prediction (p=0.002), whereas $SUV_{mean/max}$ failed in prediction for therapy response (AUC</=0.63, n.s.). **Conclusion**: The heterogeneity parameter Entropy derived by baseline SSTR-PET demonstrated superior prognostic performance in pNET patients envisaged for ERT, in particular for "borderline" G2 tumors. Strikingly, on a quantitative voxel-by-voxel analysis, a higher ordered pattern denotes less therapeutic response to peptide-based radiotherapy whereas an increase in derangement can predict longer overall survival.

OP-584

Hyperkalemia in patients treated with radioligand or peptide receptor radionuclide therapy

C. H. Pfob[1], A. Ott[2], F. Maurer[3], P. Luppa[4], K. Scheidhauer[1], U. Heemann[5], M. Schwaiger[1], C. Schmaderer[5]; [1]Department of Nuclear Medicine, Technische Universität München, Klinikum rechts der Isar, Munich, GERMANY, [2]Biomedical Informatics, Institute of Medical Statistics and Epidemiology, Technische Universität München, Klinikum rechts der Isar, Munich, GERMANY, [3]Hospital Pharmacy Department, Technische Universität München, Klinikum rechts der Isar, Munich, GERMANY, [4]TU MunichDepartment of Pathobiochemistry, Technische Universität München, Klinikum rechts der Isar, Munich, GERMANY, [5]Department of Nephrology, Technische Universität München, Klinikum rechts der Isar, Munich, GERMANY.

Background: PSMA-targeted radioligand therapy (RLT) and peptide receptor radionuclide therapy (PRRT) lead to severe hyperkalemia when combined with a potentially nephroprotective amino-acid co-infusion. This has been reported already for PRRT. The pathophysiology behind the rapid development of hyperkalemia is incompletely understood. We hypothesized that the infusion of cationic amino acids along with the acidity of the solution itself leads to increase of hydrogen ions that causes potassium shift to the extracellular space. **Methods:** 10 patients underwent cycles of PRRT or of RLT, respectively. Prior to the first cycles excretory kidney function was assessed by mercapto-acetyltriglycine (MAG-3) renal scintigraphy and serum biochemistry. For nephroprotection all patients received

co-infusion of the cationic amino-acids L-Arginine and L-Lysine starting 30 min prior each cycle and lasting for 4hrs. Clinical symptoms, electrolytes and acid-base status were measured at baseline and after 4hrs. Results: No patient developed clinical side effects. At baseline kidney function, acid base status and electrolytes were in the normal range except two patients with minor renal insufficiency. All patients developed hyperkalemia after 4hrs and more than half exhibiting severe hyperkalemia (defined as > 6mmol/l). Base excess and HCO3- were significantly lower after 4hrs. In parallel pH dropped. Whereas chloride did rise and the anion gap dropped slightly. Conclusion: Amino-acid co-infusion during PSMA-targeted RLT or PRRT leads to hyperchloremic, normal anion gap metabolic acidosis along with hyperkalemia. The metabolic acidosis might induce hyperkalemia by favouring exchange of potassium by hydrogen ions to the extracellular space. This finding offers an easy therapeutic option by correcting acidosis with commercially available bicarbonate solutions.

OP-585

Adjuvant post-operative radiosynovectomy in patients with rare cases of ankle pigmented villonodular synovitis (PVS)

I. Iakovou[1], J. Kotrotsios[1], K. Badiavas[1], M. Potoupnis[2], V. Mpalaris[1], G. Arsos[1]; [1]Academic Nuclear Medicine dpt, Papageorgiou hsp, THESSALONIKI, GREECE, [2]Academic Orthopedic dpt, Papageorgiou hsp, THESSALONIKI, GREECE.

Background: The most common location of the local nodular form of PVS is the knee joint, followed by the finger joints. Occurrence in the ankle joint is realy rare but should be considered if clinical findings are present. Treatment consists of isolated surgical resection of the neoplastic synovium. Radiosynoviorthesis (RS) is recommended as a post-operative treatment to increase the probability of a total removal of persisting PVS cells. **Methods-Patients:** We present our experience of 5 (3 women) young (19-31yrs) athletes with PVS of the ankle joint. All patient were treated in 2 stages: surgical synovectomy (SS) with arthroplasty of the ankle joint followed by adjuvant treatment with intra-articular injection of 2 mCi Re-186 performed within 2-3 months after SS. Treatment efficacy was evaluated 2,6 and 12 months after the initial RS by a questionnaire reporting the relief of limiting the daily activities pain as a percentage of the pretherapeutic joint discomfort using a visual analog scale (VAS). Relative uptake of Tc-99m-diphosphonate in the knee joint involved on the blood pool was also taken into consideration **Results***:* In the 1 out of the 5 cases a repeated Re-186 injection was needed for better outcome. The overall response rate for all knee treatments was 80%. Results in double treated joints were significantly worse than in single treated ones. A significant improvement in blood pool bone scintigraphic signs of inflammation was noticed. On the other hand, there was no influence on late diphosphonate uptake. **Conclusion:** A combination of debulking surgery with adjuvant intra-articular injection of Re-186 for the rare cases of PVS of the ankle joints seems to be a reliable treatment method, with encouraging results

OP-586

Impact of external cooling on PSMA uptake in salivary glands

*L. W. M. van Kalmthout, M. G. E. H. Lam, B. de Keizer, A. J. A. T. Braat;
University Medical Center Utrecht, Utrecht, NETHERLANDS.*

Aim: External cooling of the salivary glands with icepacks is currently common practice in patients treated with lutetium-177-PSMA-617 for advanced prostate cancer. Cooling of both parotid and submandibular glands is believed to cause vasoconstriction, resulting in a reduced blood flow to the salivary glands. Thus lowering PSMA uptake, in the hopes of decreasing the occurrence of the reported side effect xerostomia. To date however, this rationale has not been extensively investigated. Aim of this study was to determine the impact of cooling with icepacks on PSMA uptake in salivary glands. **Materials and Methods:** Nighty one patients referred for a gallium-68-PSMA-11 PET/CT for (re)staging of prostate cancer were consecutively included in this analysis. Twenty-six patients were scanned with unilateral icepacks on the left side, allowing intra-individual analysis, and 21 patients were scanned with bilateral icepacks. A control group of 44 patients was scanned without icepacks. Icepacks were applied at least 25 minutes prior to tracer injection. All icepacks were replaced for new ones 30 minutes prior to PET/CT acquisition to ensure effective cooling of the salivary glands. PET/CT acquisition started one hour post-injection. PSMA uptake (expressed by SUVmax, SUVpeak and SUVmean) was measured on standardized EARL reconstructions in both parotid glands and submandibular glands. **Results:** Patients with bilateral icepacks showed no differences in PSMA-uptake compared to the control group (all p>0.05); right parotid gland (SUVmax 11.62 versus 13.24), left parotid gland (SUVmax 11.26 versus 13.03), right submandibular gland (SUVmax 12.09 versus 12.65) and left submandibular gland (SUVmax 11.56 versus 12.37). In the unilateral icepack-group, merely a significant decrease in SUVpeak was found in the right parotid gland compared to the left side (11.07 versus 9.87; p=0.00). Regarding SUVmax and SUVmean, no differences in PSMA uptake were found between the right and left parotid gland (SUVmax 13.90 versus 11.09; p>0.05). All parameters on PSMA uptake in the right and left submandibular gland were comparable (SUVmax 13.00 versus 12.65; p>0.05). **Conclusion:** There is no need for external cooling of salivary glands using icepacks, because it does not influence PSMA uptake in salivary glands.

OP-587

Functional imaging of the salivary glands for evaluation of radiation-induced sialadenitis before and after Lu-177 PSMA radioligand therapy

T. Langbein, H. R. Kulkarni, A. Singh, R. P. Baum; Zentralklinik Bad Berka, Bad Berka, GERMANY.

Objective: During Lu-177 PSMA radioligand therapy (PRLT) of metastatic castration-resistant prostate cancer (mCRPC), an intense uptake of the radioligand in the salivary as well as in the lacrimal glands is observed. Hence, post-therapeutic xerostomia and potentially xerophthalmia are possible adverse effects. Objective of this study was to assess the function of the parotid and submandibular salivary glands by dynamic salivary gland scintigraphy (SGS) using Tc-99m pertechnetate before and after PRLT. **Methods:** We included 35 patients (median age 67 years, range 46-81), undergoing 1-3 cycles of PRLT applying a median cumulative activity of 13.3 GBq (range 6 - 24.8 GBq). For long-term follow-up 12 patients were analyzed, who received 3-9 cycles of PRLT (mean cumulative activity 32.3 GBq, range 20.1-56.4 GBq) up to 28 month after first cycle. A total of 183 SGS studies, performed since September 2015, were investigated. Dynamic images of the parotid and submandibular salivary glands were acquired 30 minutes after injection of Tc-99m pertechnetate. The salivary gland uptake and quantitative excretion fraction after an oral secretory stimulus at 15 minutes p.i. were evaluated. A standardized questionnaire (shorted xerostomia inventory) was used to investigate the occurrence of xerostomia. **Results:** Post PRLT, 12 patients reported mild dryness of mouth (mostly at night) with no influence on their everyday life. Only 3 patients reported significant xerostomia. However, 2 of them had received external beam radiation therapy for cervical spine metastasis and had scintigraphically confirmed salivary dysfunction prior to PRLT. SGS demonstrated a worsening of the salivary gland function in only 2 of the remaining 33 patients. In the follow-up-cohort, 1 out of 12 patients reported mild xerostomia, whereas 3 of the 12 SGS revealed a slightly decreased salivary function. **Conclusion:** Salivary gland scintigraphy is a very useful and easy to perform imaging modality for the objective evaluation of xerostomia following Lu-177 PSMA radioligand therapy. No significant parenchymal dysfunction of the salivary glands was observed even after several cycles of PRLT.

OP-588

Fluorocholine PET CT parameters predictive for hematological toxicity to 223Radium Therapy

M. Sinigaglia, L. Vija Racaru, S. Kanoun, S. Zerdoud, M. Bauriaud-Mallet, D. Bastié, L. Dierickx, D. Vallot, O. Caselles, P. Pascal, F. Courbon; Institut Universitaire de Cancérologie-Oncopole, Toulouse, FRANCE.

Introduction: The main objective is to identify fluorine-18 fluorocholine (FCH) PET/CT markers predictive for hematological toxicity induced by ^{223}Ra therapy, such as metabolically active bone tumor volume (MATV) and total bone lesion activity (TLA) in castrate-resistant prostate cancer (CRPC) patients. **Methods:** Baseline FCH PET/CT was performed in 15 patients with CRPC before treatment with ^{223}Ra. Bone metastatic disease was quantified on the basis of maximum standardized uptake value (SUVmax), MATV and total lesion activity (TLA = MATV × mean SUV). Tumor burden indices derived from total skeleton PET tumor volume measurements (such as MATV/ TBV, TLA/TBV, MATV/H, TLA/H; TBV: total bone volume measured on CT, H: height in m) were also evaluated. Bone metastatic disease and FCH PET/CT bone tumor burden and activity were analyzed in order to identify which parameters could predict hematological toxicity (on Hb, platelets and lymphocytes) at the end of ^{223}Ra therapy. Pearson correlation was used to identify correlations between age,

PSA, Gleason's score and FCH PET parameters. **Results:** MATV ranged from 75.15 cm^3 to 1259.38 cm^3 (median 392.72 cm^3). TLA ranged from 342.61 to 7198.11 cm^3 (median 1853.9 cm^3). 15 patients beneficiated from 56 cycles of ^{223}Ra. At the end of the therapy 33% (5/15) of patients presented grade 2/3 toxicity on hemoglobin and lymphocytes, while 20% (3/15) presented grade 2/3 platelet toxicity. Age was negatively correlated with both MATV (r=-0.612, p=0.015) and TLA (r=-0.596, p=0.018). Age, Gleason score, previous hormonal therapy, radiotherapy and docetaxel therapy were significantly associated with TLA (p<0.001). MATV, TLA and TLA/H predicted hematological toxicity on Hb, platelets and lymphocytes at the end of ^{223}Ra cycles (p<0.001, p<0.001, p<0.01). ROC curve analysis allowed to define cut-offs for MATV (914.97 cm^3), TLA (4197.76 cm^3) and TLA/H (23.31) which predicted platelet toxicity with an accuracy of 0.92, 0.99 and 0.77 respectively. **Conclusions:** The predictive value of pre-therapeutic FCH PET/CT markers: TLA and MATV for platelet toxicity after ^{223}Ra therapy may stem from the capacity of assessing whole body visceral and bone-osteomedullary infiltration, allowing better patient selection and treatment optimization.

OP-589

Baseline 18F-Fluoride PET-derived parameters predict modification of toxicity- and response-related blood biomarkers in prostate cancer patients treated with 223Ra-Dichloride: preliminary results

V. Ceriani[1], *G. Fornarini*[1], *M. Bauckneht*[1], *S. Morbelli*[1], *E. Zanardi*[1], *E. Pomposelli*[2], *A. Buschiazzo*[1], *I. Calamia*[1], *M. Ippoliti*[1], *F. Fiz*[3], *R. Piva*[1], *P. Mataceri Bettini*[1], *F. Boccardo*[1], *G. Sambuceti*[1]; [1]IRCCS AUO San Martino IST, Genova, ITALY, [2]Nuclear Medicine Unit, A.O. SS. Antonio e Biagio e Cesare Arrigo, Alessandria, ITALY, [3]Dep. of Nuclear Medicine and Clinical Molecular Imaging University Hospital, Tübingen, GERMANY.

Aim: Beyond lesion detection and staging, 18F-NaF PET can provide semiquantitative parameters expressing skeletal tumor burden and intensity of osteoblastic reaction. 223Ra-Dichloride therapy has been shown to improve survival in prostate cancer patients, however, heterogeneous responses to 223Ra has been reported. In particular, clinical variables able to identify responders before or early in the course of therapy need to be fully elucidated. In the present study we correlated baseline 18F-NaF PET-derived parameters with modification of both toxicity- and response-related blood biomarkers in prostate cancer patients treated with 223Ra-Dichloride. **Methods**: 13 patients with hormone-refractory prostate cancer undergoing 223Ra therapy in our center were enrolled in a single-institution trial from June 2016 to March 2017. Fluoride PET/CT scan was acquired at baseline and after thee cycles of 223Ra administration. Total alkaline phosphatase (ALP) and prostate-specific antigen (PSA) as well as blood cells counts were obtained at baseline, after three cycles (interim) and at the end of therapy. Maximum standardized uptake value of the hottest lesion (hSUVmax), mean SUV of all lesions (SUVmean) and total volume of fluoride avid bone metastases (TVF) were computed on Fluoride PET/CT images. Lin-

ear regression was used to assess correlation between baseline Fluoride PET-derived parameters and blood biomarkers levels at baseline, interim and end of treatment. **Results**: To date final blood biomarkers results were available in only five of the recruited patients. Accordingly, only interim evaluation was included in the present analysis. At baseline, hSUVmax, SUVmean and TVF were 50,27 (±22.2), 27,6 (±13,9) and 1628,68 (±467,9), respectively. As expected, TVF was directly related with baseline ALP and PSA (p<0.01). However, it was also directly proportional to the interim decline in platelets count and ALP (p<0.05). On the other hand, both hSUVmax and SUVmean were directly related with the interim raise in PSA (p<0.05). **Conclusion**: According to our preliminary analysis, baseline skeletal tumor burden is able to predict early signs of both response to therapy and bone marrow toxicity in prostate cancer patients treated with 223Ra. Moreover, Fluoride PET-derived indexes of osteoblastic reaction correlate with PSA flare in the early course of treatment. Whether confirmed, these preliminary data might imply a prognostic role for Fluoride-PET in prostate cancer patients candidates to 223Ra. Recruitment is still ongoing to confirm the predictive value of fluoride PET in the end of treatment setting and to correlate these data with overall survival.

OP-590

Mechanisms of Bone Marrow Failure in Prostate Cancer Patients treated with Radium-223 Therapy

F. Fiz[1], *C. Campi*[2], *S. Sahbai*[1], *J. Schwanck*[1], *M. Weissinger*[1], *M. Bauckneht*[3], *R. Piva*[3], *C. Marini*[4], *H. Dittman*[1], *M. Piana*[3], *G. Sambuceti*[3], *C. La Fougère*[1]; [1]University of Tuebingen, Tuebingen, GERMANY, [2]National Council of Resarch - SPIN, Genoa, ITALY, [3]University of Genoa, Genoa, ITALY, [4]CNR - IBFM, Genoa, ITALY.

Introduction: Radium-223 Therapy (223-Ra) is represents a safe and effective treatment options for metastasized prostate cancer. However, our previous analysis highlighted a variable distribution of bone-seeking tracers into the trabecular bone containing hematopoietic bone marrow (BM). A higher metabolism predicted a greater hematologic toxicity. Moreover, the entity of tumor burden has been linked to a higher incidence of BM toxicity. Aim of this study is to investigate the correlation between tumor burden, 223-Ra distribution to the trabecular bone and onset of Grade III-IV hematologic toxicity events. **Methods:** Pre-223-Ra whole body bisphosphonate-SPECT/CT of 76 prostate cancer patients were analyzed with a dedicated application. The algorithm automatically analyzed the bone structure, quantifying volume, mean density (HU) and mean counts (MC) of both trabecular bone as well as of the tumor voulume (TV) i.e. the bone metastases. Tumor burden was correlated with trabecular bone MC. TV, PSA level, presence of "superscan", number of lesions and presence of tumor burden in more than 50% of appendicular skeleton were tested as predictors of Grade III-IV toxicity with MANOVA. **Results:** A tight correlation between TV and trabecular MC was found (R=0,68, p<0,001). This correlation was present in the axial skeleton as well as in the long bones (p<0,01). At MANOVA, predictors of hematologic toxicity were: trabecular MC (p<0,05), TV (p<0,05), TV in long bones (p=0,008)

and appendicular invasion (p=0,004). **Conclusions:** A greater tumor burden can increase bone metabolism within trabecular bone. This could increase the delivered activity to the BM in the course of 223-Ra therapy and expose the patient to a higher risk of hematologic toxicity.

OP-591

Prediction of hematological toxicity in Radium-223 therapy in patients with advanced metastatic castration-resistant prostate cancer

M. Ø. Fosbøl, P. M. Petersen, A. Kjaer, J. Mortensen; Rigshospitalet, Copenhagen, DENMARK.

Aim: Investigate whether automated quantitative assessment of skeletal tumor burden on bone scintigraphy (Bone Scan Index) can serve as a predictive biomarker for hematological toxicity in patients with metastatic castration-resistant prostate cancer (mCRPC) receiving Radium-223-dichloride (Ra-223). **Methods:** National study of the Danish mCRPC patients who received ≥ 1 cycle of Ra-223 therapy from March 2014 to October 2015 and for whom a baseline bone scintigraphy was available. Baseline bone scintigraphies were reviewed and graded according to extent of disease (EOD). All scintigraphies were additionally analysed with the software EXINI Bone[BSI] Version 2(EXINI Diagnostics, Lund, Sweden) to obtain Bone Scan Index (BSI). Primary outcome was occurrence of hematological toxicity grade 2-5 according to Common Terminology Criteria for Adverse Events (CTCAE) commencing within 90 days from preceding Ra-223 administration. Association between BSI and hematological toxicity was evaluated in a multivariate logistic regression analysis including the following parameters: Baseline BSI, visual grading of EOD on bone scintigraphy, B-hemoglobin, leukocyte count, thrombocyte count, serum PSA and previous use of chemotherapy. **Results:** A total of 88 mCRPC patients were included in the study. EOD by visual assessment showed 75 % of patients (n=66) had > 20 metastases or superscan. Median baseline BSI was 5.0. Median number of completed Ra-223 cycles was four and only 27 patients (31%) completed all six cycles. Hematological toxicity was the cause of early discontinuation in 21 patients (23%). Anemia grade 2-4 occurred in 51 % of patients (n=45), leukopenia grade 2-4 in 30 % (n=26) and thrombocytopenia grade 2-4 in 24 % (n=21). One patient (1 %) died due to leukopenic infection following Ra-223 therapy and one patient (1%) due to thrombocytopenia and intracranial haemorrhage. Significant predictors of haematological toxicity in multivariate regression analysis were baseline BSI (OR 1.11 per unit increase, p=0.04), B-hemoglobin (OR 1.89 per unit decrease (mmol/l), p=0.04) and leukocyte count (OR 1.37 per unit decrease (10^9/l), p=0.02). Patients with baseline BSI > 5 had odds ratio of 3.02 (95% CI: 1.2-7.8, p=0.02) for grade 2-5 toxicity compared with patients with baseline BSI ≤ 5. **Conclusion:** Hematological toxicity occurred frequently in this cohort of mCRPC patients with advanced disease. BSI at baseline was a significant predictor of haematological toxicity and can potentially aid to identify patients at high risk of toxicity, for whom alternative therapy options should be considered.

OP-592

^{90}Y PET-CT based method of dose calculation to evaluate the efficacy of internal selective radiotherapy (SIRT)

E. Kalogianni, N. Heraghty, D. Levart, B. Corcoran, N. Mulholland, M. Vadrucci, G. Vivian; King's College Hospital, LONDON, UNITED KINGDOM.

Aim: The aim of this project is to evaluate the efficacy of yttrium-90 (^{90}Y) microsphere selective internal radiotherapy (SIRT) using a patient-specific PET-CT based method of dose calculation. **Methods:** Retrospective dosimetry of the standard radioembolisation treatment with resin ^{90}Y microspheres was performed for eight patients with unresectable liver metastases (six patients with colorectal liver metastases and two with cholangiocarcinomas). Injected activity calculation was performed using the body surface area (BSA) method. A 3D radiation absorbed dose distribution was estimated for each patient, using a voxel-based semi-Monte Carlo dosimetry method on post-therapy ^{90}Y-PET-CT images, with the Hermes Hybrid Dose 3D dosimetry software. Response was examined using the tumour lesion glycolysis (TLG) on ^{18}F-FDG-PET, as measured pre and post treatment (mean 2.9 ± 0.3 months post treatment). The TLG was estimated using the metabolic tumour volume at 50% threshold. Pre-treatment ^{18}F-FDG-PET was used for the VOI delineation and calculation of TLG per metastasis and was registered with the 3D absorbed dose distribution map. All processing performed using HERMES Hybrid Viewer. A linear fixed effects model was used to assess the dose and post-treatment TLG relationship. **Results:** 36 treated metastases were identified. Mean absorbed dose was 63±37 Gy (range: 4 - 156 Gy). The biological effective dose (BED) and Equivalent Uniform BED (EUBED) were calculated ($\alpha = 0.004$ Gy^{-1}, $\alpha/\beta = 10$ Gy, $T_{1/2}^{\text{Repair}} = 1.5$). BED was 77 ± 51 Gy (range: 4-214 Gy) and EUBED was 73 ± 48 Gy (range: 4 - 208 Gy). A significant relationship was found (p < 0.001), indicating that increased absorbed dose is associated with decreased post-treatment TLG (TLG$_{post}$). A significant relationship was found (p < 0.001) between pre-treatment TLG (TLG$_{pre}$) and TLG$_{post}$, indicating that the dose response-relationship depends on the TLG$_{pre}$. A statistically significant relationship was found (p < 0.001) between the BED and EUBED and TLG$_{post}$. The experimental tumour control probability (TCP) showed that TCP(50%) was 60Gy and 90Gy for tumours with TLG>100. **Conclusion:** A statistically significant dose response relationship was found as well as a relationship between the TLG$_{pre}$ and TLG$_{post}$. Individualised treatment planning options using the Technetium-99m macroaggregated human albumin (^{99m}Tc-MAA) SPECT-CT scan could potentially improve the treatment outcome.

OP-593

Correlation of SUVmax values & liver metastasis size/number with survival of colorectal Ca patients undergoing TARE treatment

B. Sönmezer[1], A. Gülcü[2], R. Bekiş[1], B. Polack[1]; [1]Dokuz Eylül University, Faculty of Medicine, Department of Nuclear Medicine, İzmir, TURKEY, [2]Dokuz Eylül University, Faculty of Medicine, Department of Radiology, İzmir, TURKEY.

Aim: In this study we aimed to assess the correlation between survival durations and SUVmax values, largest metastatic lesion size, and SUVmax tumor/background ratio in the liver on F-18 fluorodeoxyglucose (FDG) positron emission tomography (PET)/computerized tomography (CT) images of 22 patients with colorectal Ca diagnosis treated with Y-90 glass microsphere (terasphere) transarterial radioembolization (TARE) for liver metastasis at our center. **Method:** Twenty-two patients with mean age 66.1 (± 9.8) years underwent TARE treatment a total of 32 times (twice in 10 patients, once in 12 patients). On CT imaging before treatment, the sizes of metastatic foci in the liver were measured. They were classified as larger and smaller than 5 cm. SUVmax values were measured before treatment for liver metastasis. The obtained SUVmax values and background SUVmax measured in normal liver area were used to calculate the tumor/background ratio. Additionally, treatment response was evaluated according to the PET Response Criteria in Solid Tumors (PERCIST) criteria. The correlation between calculated quantitative values and survival duration was assessed with the Kaplan Meier method. **Results:** The mean size of lesions was 4.1 (1.3) cm, with mean SUVmax value of 9.7 (4.5). On F-18 FDG PET/CT images, the survival duration of patients with tumor/background ratio in the liver above 5 was 7.0 (1.6) months, while it was calculated as 20.5 (5.0) months in patients with this ratio below 5 (p=0.05). When investigated in terms of numbers of metastatic lesions in the liver on CT images before treatment, the survival duration of patients with 1 or 2 lesions was 41.0 (± 0.2) months, while for patients with multiple lesions it was 8.7 (± 1.2) months (p=0.02). For patients with largest lesion in the liver below 5 cm on CT images before treatment, survival was 16.1 (± 4.8) months, while for patients with lesions above 5 cm survival was 11.0 (± 2.1) months (p=0.9). When SUVmax values of liver metastasis measured on PET/CT images before and after treatment are assessed according to PERCIST criteria, patients with partial metabolic response survived 17.4 (± 4.2) months, while patients without partial metabolic response survived for 6.9 (± 0.7) months (p=0.3). **Conclusion:** It is considered that number of metastatic foci in the liver and tumor/background ratio may provide predictions related to survival before TARE treatment. Using these criteria in patient and treatment choice may contribute to patient management.

Prognostic impact of pre-treatment 18FDG-PET/CT restaging in patient with HNSCC

O. Delcroix[1], J. Leclère[2], P. Robin[1], S. Querellou[1], P. Le Roux[1], P. Salaun[1], C. Guezennec[1], U. Schick[3], G. Valette[2], J. Rousset[4], R. Abgral[1]; [1]Department of Nuclear Medicine, Brest University Hospital, BREST, FRANCE, [2]Department of Head and Neck Surgery, University Hospital of Brest, BREST, FRANCE, [3]Department of Radiotherapy, Brest University Hospital, BREST, FRANCE, [4]Department of Radiology, Military Hospital of Brest, BREST, FRANCE.

Introduction: Accurate initial staging of head and neck squamous cell carcinoma (HNSCC) is essential for appropriate treatment planning and outcome prediction. Several guidelines consider fluorodeoxyglucose positron emission tomography/ computed tomography (18FDG-PET/CT) as a valuable option to assess remote extension of locally advanced stage III/IV disease. This study evaluated the yield of 18FDG-PET/CT for each AJCC subgroup and the impact of 18FDG-PET/CT results on prognosis. **Subjects & Methods:** This study retrospectively included 477 patients (414M/63W; mean age 62.3 +/-9.7) with newly diagnosed HNSCC who underwent pre-treatment 18FDG-PET/CT from 2004 to April 2014. 18FDG-PET/CT staging (Stage$_{PET}$) was compared with those of conventional workups (CWU) alone

(Stage$_{CWU}$) comprising clinical examination, cervical contrast-enhanced computed tomography (CT) and/or contrast-enhanced MRI and chest CT. 18FDG-PET/CT findings were compared to histopathology when available. The prognostic impact was assessed with overall survival (OS) and progression-free survival (PFS). Tests of statistical significance were two-sided. **Results:** 18FDG-PET/CT changed the TNM (WHO classification) Stage$_{CWU}$ in 194 of 477 patients (40.7%; 95%CI = 36.3-45.1%). 18FDG-PET/CT modified nodal Stage$_{CWU}$ in 38.2% (95%CI = 33.8-42.5%) with an upstaging rate of 26.4% (95%CI = 22.5-30.4%) and a downstaging rate of 11.7% (95%CI = 8.8-14.6). Patients with 18FDG-PET/CT nodal upstaging had significantly worse 3-year OS (44.1% versus 55.9%, *P* =0.032) and PFS (30.8% versus 43.9%, *P*= 0.019) than patients with no Stage$_{CWU}$ changes. Among the 100 cases of nodal staging comparison with histopathology, 18FDG-PET/CT showed less misclassifications than CT or MRI (34 versus 40) but without statistical significacy (*P* =0.464).18FDG-PET/CT showed unsuspected distant metastases in 20 patients (4.2%; 95%CI = 2.4-6.0%). Among the 48 synchronous proven primary tumors, 35 were uncovered by 18FDG-PET/CT but not by CWU (7.3%; 95%CI = 5.0-9.7%). 18FDG-PET/CT modified TNM classification or discovered synchronous primary tumor in 16/59 (27.1%; 95%CI = 15.7-38.6%) stage I, 27/69 (39.1%; 95%CI = 27.5-50.7%) stage II and 47/76 (61.8%; 95%CI = 50.8-72.8%) stage III.Stage$_{CWU}$ I patients with 18FDG-PET/CT upstaging had significantly worse 3-year OS (50.0% versus 86.0%; *P*= 0.002) and PFS (43.8% versus 72.1%; *P*= 0.02) than other Stage$_{CWU}$ I patients. **Conclusion:** The yield of 18FDG-PET/CT appeared substantial in patients with a clinical stage I or higher HNSCC with a powerful prognostic stratification.

OP-599

Inter-observer and inter-contouring method variability for textural analysis in head and neck cancer in pre-therapeutic 18-FDG PET/CT

C. Guezennec, J. Corre, D. Bourhis, P. Robin, O. Delcroix, Y. Gobel, U. Schick, P. Salaün, R. Abgral; CHRU Morvan, Brest, FRANCE.

Aim: Characterizing tumor heterogeneity with texture indices extracted from 18F-fluorodeoxyglucose positron emission tomography (FDG-PET) is actually highly studied. Several series have showed promising results to predict survival in patients with head and neck squamous cell carcinoma (HNSCC), analyzing various tumor segmentation methods and texture indices. This preliminary study aimed at assessing the inter-observer and inter-contouring method variability when calculating different texture indices on HNSCC pre-therapeutic 18-FDG PET/CT. **Materials and Methods:** Consecutive patients with HNSCC referred in our department for a pre-treatment 18-FDG PET/CT (Biograph mCT, Siemens) from January to March 2016 were retrospectively included. Two nuclear medicine physicians independently segmented all tumors (VOI) using 3 different contouring methods: with a relative SUV threshold (40%SUVmax), a signal-to-noise adaptative SUV threshold (Daisne) and an image gradient-based method (PET EDGE™). Six usual texture indices (homogeneity, entropy, SRE, LRE, LGZE, HGZE) were calculated

using LIFEx software (www.lifexsoft.org). An intraclass correlation test was used to assess the inter-observer reproducibility, and a Pearson correlation test was used to compare texture indices measurements within the different contouring methods. **Results:** Forty-nine patients (mean age 63.8 +/- 9.4 yo) were analyzed. A too small segmented tumor VOI could not allow texture indices calculation by the software in 11, 16 and 6 cases using respectively 40%SUVmax, PET EDGE™ and Daisne contouring method. The inter-observer reproducibility analysis revealed an excellent agreement with an intraclass correlation coefficient higher than 0.97, 0.81, and 0.96 using respectively 40%SUVmax, PET-EDGE™ and Daisne method. For each texture index, a very strong correlation between results (Pearson correlation coefficient r > 0.89) was found regardless the segmentation method used, assessing a very good inter-contouring method reproducibility. **Conclusions:** This preliminary study showed an excellent agreement between observers for textural analysis of HNSCC in FDG-PET. The different methods used were also highly reproducible among themselves to measure usual texture indices.

OP-600

PET/CT imaging of angiogenesis in head and neck squamous cell carcinoma patients

D. Lobeek[1], S. Y. A. Terry[2], M. A. W. Merkx[1], R. P. Takes[1], P. J. Slootweg[1], W. J. G. Oyen[1,3], O. C. Boerman[1], M. Rijpkema[1]; [1]Radboud University Medical Center Nijmegen, Nijmegen, NETHERLANDS, [2]King's College London, London, UNITED KINGDOM, [3]Institute of Cancer Research, Royal Marsden NHS Trust, London, UNITED KINGDOM.

Introduction: One of the features of angiogenesis is the overexpression of integrins on the cell surface of endothelial cells. To study the process of angiogenesis, we have developed an $\alpha_v\beta_3$ integrin-targeting dimeric RGD peptide for PET/CT imaging: ^{68}Ga-DOTA-E-[c(RGDfK)]$_2$ (^{68}Ga-RGD$_2$). PET/CT imaging of $\alpha_v\beta_3$ integrins may be used to characterize tumours and predict and/or assess response of (anti-angiogenic) cancer therapies. The aim of the current study is to determine the feasibility and safety of ^{68}Ga-RGD$_2$ PET/CT imaging in head and neck squamous cell carcinomas (HNSCC) and to evaluate the optimal acquisition time for ^{68}Ga-RGD$_2$ PET/CT imaging. **Subjects & Methods:** Five patients with proven squamous cell carcinomas in the oral cavity were administered intravenously with ^{68}Ga-DOTA-E-[c(RGDfK)]$_2$ (70 µg) and subsequently underwent sequential whole body PET/CT imaging at 30, 60, and 90 minutes after injection. Tracer uptake in tumour lesions was quantified as peak Standardized Uptake Values (SUV$_{peak}$); tracer uptake in muscle tissue (trapezius muscle) and blood (aortic arch) was quantified as mean SUV (SUV$_{mean}$) within a spherical volume of interest. Safety analysis included clinical examination of vital signs and analysis of blood samples taken before, during and after radiotracer injection. Additionally, immunohistochemical analysis with the anti-$\alpha_v\beta_3$ monoclonal antibody LM609 on surgically removed tumour tissue was performed to assess $\alpha_v\beta_3$ integrin expression in tumour tissue. **Results:** After intravenous injection of ^{68}Ga-RGD$_2$ (mean activity 208.66 MBq/patient, range 201-217 MBq), tracer accumulation in the tumour was visible at all imaging time

points for all patients. No drug related adverse events or changes in kidney- or liver function were observed. Tumour SUV_{peak} of ^{68}Ga-RGD_2 at the three imaging time points were 5.2 ± 0.6, 5.1 ± 1.0, and 4.4 ± 0.9, respectively. Tumour-to-muscle (TMR) and tumour-to-blood (TBR) ratios at the three imaging time points were 9.0, 10.9, 11.0, and 4.9, 6.9, 8.2, respectively. Immunohistochemical analysis confirmed $\alpha_v\beta_3$ integrin expression on the tumour neovasculature. **Conclusion:** These preliminary results show that ^{68}Ga-RGD_2 PET/CT imaging of $\alpha_v\beta_3$ integrin expression in HNSCC patients is feasible. At this dose level, no toxicities or adverse events were observed. Whereas ^{68}Ga-RGD_2 uptake in tumour lesions was highest at 30 and 60 minutes post injection, TBR further increased over time. These findings support the hypothesis for an optimal acquisition time for ^{68}Ga-RGD_2 PET/CT at 60 minutes post injection.

OP-601

Voxel based comparison and texture analysis of ^{18}F-FDG and ^{18}F-FMISO PET of 38 Patients with head-and-neck cancer

M. Kroenke[1,2], K. Hirata[2], S. Watanabe[2], S. Okamoto[2], K. Magota[2], T. Shiga[2], Y. Kuge[3], N. Tamaki[2]; [1]Department of Nuclear Medicine, Klinikum rechts der Isar, Technical University Munich, München, GERMANY, [2]Department of Nuclear Medicine, Graduate School of Medicine of Hokkaido University, Sapporo, JAPAN, [3]Central Institute of Isotope Science, of Hokkaido University, Sapporo, JAPAN.

Introduction: ^{18}F-FMISO (FMISO) is a common tracer to assess tumour hypoxia but it is far less common than ^{18}F-FDG (FDG) in the evaluation of tumours in general. Hypoxia is an important factor for treatment as it can lead to increased radiation resistance and is an independent prognostic marker for outcome. Therefore, we try to predict hypoxia from FDG PET with new techniques of voxel based analysis and texture analysis. **Methods:** Thirty-eight patients with head-and-neck cancer underwent consecutive FDG and FMISO PET scans before any treatments. ROIs enclosing the primary tumour were compared in a voxel-by-voxel manner between FDG and FMISO PET. Tumour hypoxia was defined as the volume with a tumour-to-muscle ratio > 1.25 in the FMISO PET and hyper-metabolism was defined as 50 % SUVmax in the FDG PET. The concordance rate was defined as percentage of voxels within the tumour which were both hypermetabolic and hypoxic. Texture analysis was performed by calculating 38 different parameters on all ROIs and correlated. **Results:** A moderate correlation between FDG and FMISO uptake was found by a voxel-by-voxel comparison (r=0.664, p<0.001). The mean concordance rate was 27 %, ranging from 0 to 74 %. The hypoxic tumour regions showed a twice fold increased FDG uptake compared to the non-hypoxic tumour regions (SUVmean 10.9 vs. 5.4; p<0.001). The maximum of the significant correlation coefficients between texture analysis parameters of FDG PET and tumour hypoxia was 0.524. **Conclusion:** FDG uptake was higher in hypoxic tumour regions than in non-hypoxic regions. Moderate correlations between FDG and FMISO PET were found by voxel-based analysis. However, it may be difficult to predict tumour hypoxia even with the help of texture analysis.

OP-602

Role of FDG-PET in disclosing RECIST-based pseudoprogression in non-small cell lung cancer (NSCLC) patients treated with Nivolumab

M. Bauckneht, G. Rossi, R. Piva, C. Genova, E. Rijavec, G. Barletta, F. Biello, V. Ceriani, I. Calamia, G. Dal Bello, R. Di Stefano, G. Sambuceti, F. Grossi, S. Morbelli; IRCCS AUO San Martino IST, Genova, ITALY.

Background: Anti-cancer immune reaction provided by immune check-point inhibitors (ICPIs) might initially increase total tumor burden due to inflammation and may be confused with progressive disease (PD), hampering dimensional response evaluation based on RECIST criteria. The aim of the study is to explore the potential role of FDG-PET to provide an early prognostic stratification at first response in patients classified as RECIST-PD after Nivolumab administration for NSCLC. **Methods:** 55 patients with advanced NSCLC were treated with Nivolumab (4 mg/Kg every 14 days) within a single-institutional research trial. First-response after four cycles of Nivolumab was assessed by means contrast-enhanced CT and FDG-PET. CT scans were evaluated by means of RECIST criteria. In patients classified as RECIST-PD, metabolic response was evaluated either by means of PERCIST criteria or by computing the percentage of reduction of Metabolic Tumor Volume (MTV) and Total Lesion Glycolysis (TLG). Kaplan-Meier analysis estimated the overall survival (OS) according to the different outcomes PERCIST, MTV and TLG response groups after a follow-up of 20 months. **Results:** As expected RECIST criteria were rather insensitive in the evaluation of response to Nivolumab. In fact, 28/55 patients were classified as RECIST-PD at first response (21 male, 7 female; mean age 69±2.3 years). Conversely, among PD-RECIST, at first metabolic response 14, 24 and 22 patients were classified as PD, while 2, 4 and 6 patients were classified as in partial response according to PERCIST, MTV and TLG, respectively. The stratification according to PERCIST and TGL was able to identify a subgroup of patients with longer OS. In fact, after one year, 50% of PERCIST and 60% of TLG responders were still alive. The prognostic relevance of PERCIST response was still evident after 20 months of follow-up while at one year TLG responders and non-responders curves significantly approached each other. By contrast, percentage of variation in MTV was not able to discriminate pseudoprogression in the whole group of RECIST-PD. Similarly, patients classified as PERCIST stable disease showed an OS overlapping PD PERCIST. **Conclusion**: Metabolic response according to PERCIST and TLG seems to early identify a subgroup of RECIST-PD with a better prognosis. PERCIST predicted patients' survival as long as 20 months after therapy initiation, while TLG was able to identify a larger number of RECIST pseudoprogressions losing its prognostic power one year after therapy. Metabolic response based on either PERCIST or TLG may improve the therapeutic decision-making in NSCLC patients treated with Nivolumab.

OP-603

Heterogeneity in tumours; Validating the use of textural analysis and shape analysis on 18F-FDG PET/CT scans of lung cancer patients as a prognostic tool. Preliminary analysis

M. M. K. Krarup[1], L. Nygård[1], I. Vogelius[1], M. M. Siddique[2], G. Cook[3], V. Goh[2], F. L. Andersen[1], B. M. Fischer[1]; [1]University Hospital of Copenhagen, Rigshospitalet, Copenhagen, DENMARK, [2]St. thomas', Guy's Hospital/King's College, London, UNITED KINGDOM, [3]St. Thomas', Guy's Hospital/King's College, London, UNITED KINGDOM.

Aim: The purpose of this study is to validate selected textural features (TF) and shape features in a cohort of Non Small Cell Lung Cancer (NSCLC) patients. We will evaluate TF and shape features from 18F FDG PET/CT-scans as predictors of progression free survival (PFS) in combination UICC stage, histology and Gross Tumor Volume (GTV) measured for radiotherapy. With this study we wish to determine robust data, which can support texture and shape analysis as a clinical tool. **Materials and Methods:** TF and shape features previously reported to be diagnostic, prognostic and reproducible were chosen for the textural analysis (TA). 18F FDG PET/CT scans performed for radiotherapy planning in NSCLC patients were retrospectively retrieved. An isocontour corresponding to 40% of SUVmax was drawn semi-automatically on PET images, encompassing the primary tumour. TA was performed on Feature Analysis Software Tool (FAST) to evaluate TF and shape features on PET and CT images. The features were compared with PFS by a univariate cox regression analysis. Subsequently, Spearman Rank Test was done to evaluate correlation with GTV and other TF or shape features. Significant features from the univariate analysis with minimum correlation index were chosen for inclusion in a multivariate cox regression analysis as added value to a baseline model including histology, clinical stage and GTV. The baseline model were compared with the baseline model+ TF or shape feature using cross validation (100 Bootstrap samples) with AUC as the performance metric. **Results:** TA was performed on scans from 173 patients (105 males, 68 females, mean age: 66) with clinical stage II-IV, and histology being adenocarcinoma, squamous cell, and other. Mean GTV was 115 cm^3 (SD 112 cm^3). The univariate cox regression analysis showed the following features to be significant in predicting PFS: First Order Entropy (p=0,017), Difference Entropy (p=0,006) and Grey Level Non Uniformity (GLNU) (p=0,035) from CT-images. After testing for correlation using the spearman rank test, First Order Entropy and GLNU were chosen for inclusion in the multivariate analysis. First order entropy from CT images was independently significant (p=0,018) in the subsequent multivariate cox regression analysis with the baseline model. **Conclusion:** First order entropy from CT-images shows independently significant association with PFS in the multivariate cox regression analysis including UICC stage, histology and GTV. No TF or shape features derived from PET data were independent predictors.

Moscati Hospital, Avellino, ITALY, [15]Department of Medicine and Surgery, University of Salerno, Baronissi (SA), ITALY.

Aim: The ITALIANtrial sought to compare the diagnostic information by segmental PET/CT(s-PET/CT)with wb-PET/CT and to estimate dosimetric and temporal impacts of segmental imaging. **Methods:** Between 2014 and 2016, we retrospectively selected 314 consecutive patients(age 67years) investigated by FDG-PET/CT for SPN characterization. Patients in staging and those with prior cancer history were excluded. Patients were stratified according to clinical and instrumental pre-test and post-test probability of malignancy. SPN FDG uptake was semi-quantitatively assessed by a 4-point scoring system(from 1=absent to 4=intense). Significant predictors of extra-thoracic metastases were assessed by logistic univariate and multivariate analyses. **Results:** A total of 331 pulmonary nodules(average diameter of 16±7 mm)were found. Based on histological and followup data, there were 36.5% malignant, 36.5% benign and 27% indeterminate pulmonary nodules. Pre and post-test malignancy prediction risks were 27±24% and 41±39%, respectively. SPN FDG uptake was from 1 to 4 point in 28%, 26%, 10% and 36%, respectively. Among all patients, 15 (5%) had an extra-thoracic FDG uptake suspected for cancer. However, only in 7/15 patients, the extra-thoracic activity was suspicious for metastatic lesions from pulmonary nodule. CT dose length product was 573±385, with an estimate of the effective dose of 8.6±5.7 mSv. FDG dose was 277±70 mBq(4.4±1.1 mSv). At multivariate analysis, SPN FDG activity, emphysema, post-test probability of malignancy and thoracic cancer sites, were independent predictors of extra-thoracic metastases(all p<0.001). The number of beds for wb-PET/CT was 6.6±1, while those to cover the chest was 2.4±0.7, with a 2.75 ratio. Compared to wb-PET/CT, s-PET/CT with a standard FDG dose saved 6 min and 3 sec for scan. Moreover, segmental scan saved about 36% of the standard FDG dose (100 vs. 277 mBq). Mean effective dose was 13 mSv for wb-PET/CT and 4.7 mSv for s-PET/CT. **Conclusions:** The preliminary results of this

multicentre trial show that it is conceivable to perform s-PET/TC in patients with SPN. This imaging approach reduces the effective dose and associated risk of cancer. Failure to identify extra-thoracic lesions seems to be negligible in patients without intense FDG uptake of SPN, emphysema and thoracic metastasis. Thus, in selected populations segmental imaging might improve cost-effectiveness.

OP-605

Quantitative 99mTc-Galacto-RGD2 SPECT/CT to Evaluate Lung Cancer Physiology and Malignancy: A Comparative Multi-center Study with 18F-FDG PET/CT

T. Wang[1], Y. Liang[2], G. Zhang[1], M. Li[3], W. Fang[4], H. Dai[5], B. He[6], X. Wang[1]; [1]The Affiliated Hospital of Inner Mongolia Medical University, Hohhot, CHINA, [2]Navy General Hospital, Beijing, CHINA, [3]First Hospital of Shanxi Medical University, Taiyuan, CHINA, [4]Fuwai Hospital, Beijing, CHINA, [5]Dianli Hospital, Beijing, CHINA, [6]University of Missouri-Columbia, Columbia, MO, UNITED STATES OF AMERICA.

Objectives: 99mTc-Galacto-RGD2 (RGD) has been reported as a feasible tracer to assess tumor angiogenesis and metastasis, but limited to quantitatively evaluate tumor physiology and malignancy by only conventional SPECT/CT imaging. We aim to quantify integrin-$\alpha v \beta 3$ expression in lung tumors with quantitative RGD SPECT and compare physiological parameters with glucose metabolism by FDG PET. **Methods:** Twenty-eight biopsy-confirmed patients with non-small cell lung cancer were enrolled to receive both RGD SPECT/CT and FDG PET/CT scans at three medical centers in China. RGD SPECT images were reconstructed with full physical corrections (attenuation, scatter, collimator blur and noise) while PET images were processed according to the clinical routine. All SPECT, SPECT/CT and PET/CT cameras were pre-qualified to enter the study and cross calibrated imaging factors to measure radionuclide concentration in (Bq/ml). Localization of tumors in lung regions was performed by SPECT-CT and PET-CT image fusion. RGD and FDG SUVmax, SUVmean and metabolic volume (MTV, threshold≥45% SUVmax) were measured and compared to assess the malignancy of lung tumors. **Results:** When measuring Tc99m and F18 radionuclide concentration in cylindrical phantom, all SPECT, SPECT/CT and PET/CT cameras were able to achieve >97% accuracy. Total number of lung tumors (41 vs 43), SUVmax (7.74±3.38 vs 8.81±2.91), SUV mean (3.67±1.23 vs 4.46±1.38) found by RGD SPECT and FDG PET were comparable. Among matched tumors (n=38), linear correlation of RGD and FDG SUVmax was strong (y=0.49x, R=0.78) while correlations for SUVmean and MTV were moderate (SUVmean: y=0.38x, R=0.67; MTV: y=0.97x, R=0.28) (All p<0.0001). Increased RGD SUVmax highly corresponded with increased FDG SUVmax to indicate elevated tumor malignancy. **Conclusions:** Quantitative 99mTc-Galacto-RGD2 SPECT/CT with full physical corrections is a feasible approach to measure tumor integrin-$\alpha v \beta 3$ expression. It can provide another insight to quantitatively assess tumor physiology and malignancy beside FDG PET/CT scan.

Cardiovascular System: Myocardial Perfusion SPECT: Quantification & Artificial Intelligence

OP-606

Evaluating stress and rest absolute quantification of uptake in myocardial perfusion SPECT using GE Q.Metrix

I. Armstrong, N. Fyfe, P. Arumugam; Central Manchester University Hospitals, Manchester, UNITED KINGDOM.

Aims: Measurement of absolute myocardial blood flow (MBF) and coronary flow reserve (CFR) using PET is now a clinical tool that potentially overcomes some of the pitfalls of relative perfusion assessment. MBF measurement with myocardial perfusion SPECT (MPS) is technically challenging. It has been suggested that differences in absolute tracer uptake for stress-rest MPS may be a surrogate for CFR. We believe this is the first report to evaluate absolute uptake differences between stress and rest in clinical MPS studies. **Method:** Static stress and rest MPS data from 65 patients (39 male; median [inter-quartile range (IQR)] weight: 77.5kg [64.3-91.3kg]; median [IQR] BMI: 27.6kg/m^2 [25.3-32.3kg/m^2]) were included. Patients were administered tetrofosmin activity according to a sliding BMI-based protocol, and scanned at a median [IQR] time of 66 [52-77] minutes post-injection. All data were acquired on a GE Optima 640 with LEHR collimators, 180-degree orbit, 6.8mm pixels and 30-seconds/projection. Reconstruction of attenuation and scatter corrected images was performed using GE Q.Metrix as per vendor-defined parameters of 4 iterations, 10 subsets and no post-filter. SUV was calculated in the entire left ventricle (LV) of the myocardium and normalised to body weight. SUV$_{max}$ and SUV$_{mean}$ were calculated with the latter using a 25% threshold of the maximum voxel. **Results:** The median [IQR] LV SUV$_{max}$ and SUV$_{mean}$ for stress images were 10.6 [9.1-13.4] and 4.3 [3.7-5.1] respectively and for the rest images they were 11.1 [8.7-12.5] and 4.2 [3.6-4.8]. The median [IQR] in absolute LV SUV$_{max}$ and SUV$_{mean}$ difference for stress, relative to rest, was +0.4 [-1.0 to +1.9] and +0.3 [-0.3 to +0.7] respectively. The median [IQR] in relative LV SUV$_{max}$ and SUV$_{mean}$ difference for stress, relative to rest, was +4.6% [-10.9% to +18.0%] and +5.9% [-8.2% to +18.4%] respectively. Differences between stress and rest across the entire group were not significant however, for the 38 cases reported as normal, the SUV$_{mean}$ was significantly greater in the stress images compared with the rest (P<0.05) with a median [IQR] relative change of +9.1% [-7.8% to +19.4%]. **Conclusion:** These initial data suggest absolute SUV quantification in MPS shows promise and may aid reporter confidence for normal cases, with follow-up required to support findings. Q.Metrix is not a cardiac package and so results from SUV polar maps may be useful. Work is on-going to develop techniques to calculate regional SUV polar maps for MPS and evaluate the impact of alternative reconstruction parameters.

OP-607

Dynamic Single Photon Emission Computer Tomography in assessment of Coronary Flow Reserve in Patients with stable coronary artery diseases

A. Mochula[1], K. Zavadovsky[1,2], S. Andreev[1], Y. Lishmanov[2,1]; [1]Cardiology Research Institute, Tomsk NRMC, Tomsk, RUSSIAN FEDERATION, [2]National Research Tomsk Polytechnic University, Tomsk, RUSSIAN FEDERATION.

Purpose: To assess the coronary flow reserve in patients with one, two and multi-vessel coronary artery diseases by dynamic SPECT using semiconductor (cadmium-zinc-telluride)-based gamma camera. **Material and Methods:** This work included forty four patients with stable coronary artery diseases. The first group included patients with multi-vessel coronary artery diseases (MVCAD) (22 males and 8 females; mean age 60,1±4,3 years) with a lesion >70% in at least 2 major epicardial vessels according to invasive coronary angiography. Second group consisted of patients with single and two-vessel coronary artery disease (STCAD) (8 males and 6 females; mean age 61,5±3,8 years) with intermediate (40-70%) and significant (>70%) coronary artery stenosis. All patients underwent rest-stress dynamic SPECT as well as conventional myocardial perfusion imaging with 99mTc-MIBI as a radiopharmaceutical. Dynamic SPECT acquisition protocol was as follows: (1) rest radiopharmaceutical injection (volume 1 mL; dose 185 MBq); 5-min list-mode acquisition; (2) stress radiopharmaceutical injection (volume 1ml; dose 740 MBq) followed by two-minute adenosine infusion (160 mcg/kg/min); then additional two-minute adenosine infusion (160 mcg/k/min). All scintigraphic images were acquired on the hybrid SPECT/CT unit (GE Discovery NM/CT 570C). Using specialized software (4DM Reserve), we estimated the following indicators: summed stress score (SSS), coronary flow reserve for the heart as a whole (gCFR) as well as for the three coronary artery territories (LAD, LCx, RCA) - regional coronary flow reserve (rCFR). Patient with STCAD underwent invasive FFR detection. **Results:** The average value of the gCFR index was lower in a MVCAD group 1.28 (1,01;1.52) than in patient with STCAD 1.67 (1.36;2.13); p<0.05. However, in these groups there was no difference in the SSS values. Regional coronary flow reserve indexes did not differ significantly in patients with MVCAD and STCAD. ROC analysis showed that the gMFR ≤ 1,42 allows to identify MVCAD with a sensitivity and specificity 68% and 86,4%, respectively. In the second group we founded a strong correlation between the rCFR and FFR (r=0.76, p<0.05). **Conclusion:** Dynamic myocardial rest-stress SPECT using semiconductor (cadmium-zinc-telluride)-based gamma camera allows to determine low coronary flow reserve and identify MVCAD with sensitivity and specificity 68% and 86,4%, respectively. There is good relationship between rCFR and invasive FFR. It will allow to assess the hemodynamic significance of coronary artery stenosis by using dynamic SPECT. The study was supported by a grant from the Russian Science Foundation (№14-15-00178).

OP-608

One-day protocol for myocardial perfusion stress-testing by combination of Rutland-Patlak analysis of 99mTc-MIBI uptake and adenosine challenge

W. Y. Ussov[1], V. M. Gulyaev[1], E. N. Karpov[2], O. Y. Borodin[1,2], E. A. Aleksandrova[1]; [1]Institute of Cardiology, Tomsk, RUSSIAN FEDERATION, [2]Tomsk Regional Institute of Oncology, Tomsk, RUSSIAN FEDERATION.

Purpose: Currently the myocardial blood flow stress-testing with 99mTc-MIBI SPECT is being carried out with two-days protocol or employs splitting of dose. We attepted to design a protocol of myocardial blood flow (MBF) rest/stress 99mTc-MIBI SPECT imaging as single study. **Subjects and Methods:** The theory of the methods was based on assumption of unidirectional transport of 99mTc-MIBI to the myocardium for early minutes after injection. As the dynamic uptake of 99mTc-MIBI to myocardium is subjected to equation $(dC_{myoc}/dt) = EF*MBF*C_{blood}$, where C-concentration in myocardium and inflowing blood, EF - extraction fraction and the MBF - myocardial blood flow, the MBF can be obtained from running slope of plot drawn in coordinates (dC_{myoc}/dt) as ordinate and C_{blood} as abscissa, corrected for EF. Then the pharmacologic stress-test can be carried out without interruption of study, and quantified as rise in plot slope value. The technique was tested in 15 patients with stenosis of two or more coronary arteries for > 60% and previous myocardial infarction. The 99mTc-MIBI was infused intravenously slowly as 65 -74 Mbq/min for up to 12 min, with acquisition of whole-chest set of 7-10 mm slices every 20 sec, using dual-head SPECT-CT scanner, with subsequent CT coronary angiography. The calculation of MBF has been carried out as described, with simultaneous acquisition of C_{blood} from left ventricle (LV) cavity and C_{myoc} from 16 segments of the LV myocardium. In everybody the adenosine test was performed at 6 min of protocol as 2 min long infusion of 140 mkg/kgBW/min. Myocardial blood flow reserve was quantified as ratio $\{MBF_{stress} / MBF_{\text{brest}}\}$. **Results:** The average myocardial blood flow at rest was obtained as high as 68 +- 7 ml/min/100 g. Perfusion reserve in stenosis - dependent regiones of myocardium was as low as 1.10 - 1.45, whereas in normal ones as big as 1.75 - 2.90. In two patients all of whom have had transmural myocardial infarction adenosin test induced extensive deterioration of myocardial blood flow concomitantly with drop of mean arterial pressure for 15 - 25 mm Hg. Plaques with micro haemorrhages were concomitant with perfusion reserve below 1,28 in everyone and thus can be reported as of high risk in every case. **Conclusion**: Quantitative dynamic 99mTc-MIBI SPECT study combined with CT coronarography provides adequate quantification of myocardial blood flow in absolute units at pharmacologic stress-tests and reveals the clinic and haemodynamic significance of the coronary stenoses.

OP-609

Modelling Factors Affecting Apparent Transmural Flow Gradient in Ungated Tomographic Myocardial Perfusion Imaging

A. Bellini[1], C. Marini[2], F. Ticconi[1], S. D. Morbelli[3], M. Bauckneht[1], F. Fiz[4], I. Calamia[1], A. Nieri[1], S. Maggio[3], G. Sambuceti[1,3]; [1]Nuclear Medicine Unit, Department of Health Sciences, University of Genoa, Genoa, ITALY, [2]CNR Institute of Bioimages and Molecular Physiology, Milan, ITALY, [3]IRCCS AOU San Martino-IST, Genoa, ITALY, [4]Nuclear Medicine Unit, Department of Radiology, Uni-Klinikum Tübingen, Tübingen, GERMANY.

Purpose: Coronary physiology implies a greater vulnerability to ischemia for inner layers of the left ventricular (LV) myocardium. Despite a number of possible approaches to describe transmural flow gradient with nuclear methods, the need for relatively long acquisition time inevitably hampers this task due to the blurring effects caused by the cyclic modification of LV shape, volume and thickness during cardiac contraction. In the present study, we used a mathematical 3D model to test the theoretical implications of heart rate and LV function on estimated transmural flow gradient. **Subjects and Methods:** The LV mathematical model was created in MATLAB with the following assumptions: parabolic shape of external and internal wall and incompressible myocardium without any transmural gradient in blood flow. LV volume curve was modeled as a function of heart rate as previously described to account for the relative increase in diastolic phase duration under bradycardia. The partial volume effect was also taken into account by considering a progressive increase in regional counting rates up to its maximum with end-systole/end-diastole recovery coefficient ratio at 1.2. Heartbeat was divided in 8 frames and a representative short-axis view of LV myocardium was considered. Thereafter, all simulated frames were overlapped into one single image to estimate the sub-endocardial/sub-epicardial flow ratio. The model was tested at different heart rates (from 45 to 120 bpm) and different ejection fractions (from 35% to 55%). **Results:** Ungated image correctly reported a homogeneous transmural flow distribution only in the presence of a normal LV function and for heart rate approaching 90 bpm. However sub-endocardial/sub-epicardial radioactivity ratio progressively increased as a direct function of heart rate from a minimum 0.74 at 45 bpm up to its maximum of 1.38 at a heart rate of 120 bpm. This direct dependence of transmural radioactivity measurements on heart rate was further enhanced by the presence of LV dysfunction whose association with bradycardia decreased sub-endocardial/sub-epicardial radioactivity ratio down to 0.38. **Conclusion:** Our mathematical model shows that cardiac contraction profoundly affects the apparent transmural distribution of radioactivity in the LV wall when ungated images are analyzed. This effect is dependent upon the effect of heart rate on the shape of LV-volume curve during cardiac cycle and is further enhanced by the presence of contractile impairment. These data suggest the need for caution in interpreting transmural flow distribution in static images and indicate a potential relevance for ECG gated acquisition to approach this issue.

OP-610

Simulation of Patient Motion with Myocardial Perfusion CZT SPECT: Data-Driven Motion Detection and Correction

D. Daou[1,2], R. Sabbah[3], Y. Alattar[1], C. Coaguila[4], H. Boulahdour[3,5]; [1]Cochin Hospital, APHP, PARIS, FRANCE, [2]EA 7334 REMES, Université Paris-Diderot, Sorbonne Paris-Cité, Paris, FRANCE, [3]CHU Jean Minjoz, Besançon, FRANCE, [4]Centre Hospitalier de Bigorre, Tarbes, FRANCE, [5]EA 4662, Université de Franche-Comté, Besançon, FRANCE.

Aim: We previously reported the feasibility and impact on myocardial perfusion imaging (MPI) of a data-driven respiratory-motion (RM) correction method (REGAT, REspiratory GATing) applicable to CZT SPECT. In this study, we aimed to evaluate the use of REGAT for the detection and correction of simulated patient motion using MPI CZT SPECT. Materials and Methods: We used an acquired patient MPI CZT SPECT study (DNM 530c) and simulated patient motion in the X, Y and Z axis by generating dynamic studies consisting each of a combination of 16 CZT SPECT studies shifted linearly using different magnitudes. These magnitudes were (pixel size at acquisition=2.46 mm): X0Y0Z6 (maximal motion=6 pixels in +Z direction); X0Y0Z-6 (6 pixels in -Z direction); X0Y6Z0 (6 pixels in +Y direction); X0Y-6Z0 (6 pixels in -Y direction); X6Y0Z0 (6 pixels in +X direction); X-6Y0Z0 (6 pixels in -X direction); X4.5Y6Z0 (4.5 pixels in +X direction and 6 pixels in +Y direction); X-4.5Y0Z3 (4.5 pixels in -X direction and 3 pixels in +Z direction); X4.5Y0Z3 (4.5 pixels in +X direction and 3 pixels in +Z direction); X4.5Y0Z-3 (4.5 pixels in +X direction and 3 pixels in -Z direction); X4.5Y0Z3 (4.5 pixels in +X direction and 3 pixels in +Z direction); X0Y6Z-3 (6 pixels in +Y direction and 3 pixels in -Z direction); and X0Y6Z3 (6 pixels in +Y direction and 3 pixels in +Z direction). All simulated dynamic SPECT acquisitions were processed with REGAT. Briefly, REGAT generates motion curves, allows the generation of patient's motion GSPECT studies based on amplitude of curves, realigns studies and provides cardiac motion magnitudes in the patient's X, Y, and Z axis. Results: Cardiac motion magnitude detected by REGAT were -1.1 / -0.5 / 4.8 pixels for X0Y0Z6; +1.0 / +0.3 / -4.6 pixels for X0Y0Z-6; +0.1 / +5.7 / -0.1 pixels for X0Y6Z0; -0.1 / -5.8 / -0.1 pixels for X0Y-6Z0; -4.5 / -0.1 / -0.7 pixels for X6Y0Z0; +5.5 / +0.2 / -0.6 pixels for X-6Y0Z0; -3.9 / +6.4 / +0.2 pixels for X4.5Y6Z0; -3.8 / -0.3 / +1.7 pixels for X-4.5Y0Z3; +2.8 / -0.1 / +2.9 pixels for X4.5Y0Z3; +3.8 / +0.3 / -2.2 pixels for X4.5Y0Z-3; -0.7 / -6.0 / -2.4 pixels for X0Y6Z-3; and -0.4 / +5.5 / +2.3 pixels for X0Y6Z3 in respectively the X, Y and Z axis. Conclusion: Data-driven motion detection with REGAT is feasible. The detected motion magnitude is well concordant with the simulated motion magnitude.

Artificial Intelligence for Myocardial Perfusion Imaging Compared with Expert Interpretation

K. Nakajima[1], K. Kiso[2], T. Kudo[3], Y. Taniguchi[4], S. Matsuo[1], M. Nakagawa[5], T. Nakata[6], S. Hida[7], H. Tanaka[8], M. Sarai[9], K. Yokoyama[10], M. Momose[11], K. Okuda[12], L. Edenbrandt[13]; [1]Kanazawa University Hospital, Kanazawa, JAPAN, [2]National Cerebral and Cardiovascular Center, Osaka, JAPAN, [3]Nagasaki University, Nagasaki, JAPAN, [4]Hyogo Brain and Heart Center, Himeji, JAPAN, [5]Akita City Hospital, Akita, JAPAN, [6]Hakodate Goryoukaku Hospital, Hakodate, JAPAN, [7]Tokyo Medical University Hospital, Tokyo, JAPAN, [8]Tokyo Medical University Ibaraki Medical Center, Ibaraki, JAPAN, [9]Fujita Health University Hospital, Toyoake, JAPAN, [10]Public Central Hospital of Matto Ishikawa, Hakusan, JAPAN, [11]Tokyo Women's Medical University, Tokyo, JAPAN, [12]Kanazawa Medical University, Uchinada, JAPAN, [13]University of Gothenburg, Gothenburg, SWEDEN.

Aim: While application of artificial neural network (ANN) for the diagnosis of coronary artery disease (CAD) has been in-

vestigated, the diagnostic accuracy depends on how the ANN system learns expert interpretation. The purpose of this study was to create a new computer-aided diagnostic system with multicenter collaborations and to validate its diagnostic accuracy compared with nuclear cardiology expert interpretation. **Methods:** Twelve hospitals collaborated in accumulating training data for the ANN regarding presence or absence of ischemia and/or stress defects in gated stress-rest Tc-99m MIBI studies from 1,001 patients. First, an automated algorithm for detection and delineation of potential areas of ischemia or stress defects was applied. Second, an ANN was trained to classify these areas as true/false abnormality based on expert interpretations by six nuclear cardiology experts in the core center. Finally appropriate diagnostic features were adjusted for final ANN systems to provide optimal diagnostic accuracy. For the validation study, a new database consisting of 364 patients from multiple centers was used, and diagnostic accuracy of the ANN system was compared with the expert interpretation, which was used as a gold standard of abnormality. Conventional summed stress/rest/difference scores (SSS/SRS/SDS) were automatically calculated and used for comparison. Receiver-operating characteristic (ROC) was performed with area under the curve (AUC) calculation. **Results:** The training databases included ischemia and stress defect in 59% and 71% of patients, respectively. The ROC AUC for the training database was 0.91 with sensitivity/specificity of 86%/77%. The validation dataset included stress defect in 59% and ischemia in 73%, and multi-vessel disease in 40% of the patients. To identify abnormal perfusion during stress, ROC AUC of SSS was 0.82, while ANN provided better AUC (0.92, p<0.0001). Regarding stress-induced ischemia, ROC AUC of SDS was 0.75, and ANN provided significantly higher AUC (0.90, p<0.0001). ROC AUC with old myocardial infarction was 0.97 using rest-defect ANN, which was better than SRS (AUC 0.91, p=0.006). ROC AUC with and without history of revascularization using stress defect was 0.94 and 0.90, respectively, which was again better than SSS (p=0.006 and <0.0001, respectively). When the score and the probability of abnormality were compared, the SSS/SRS/SDS increased steeply when probability of abnormality was >0.80. **Conclusion:** The ANN system developed by the multicenter project showed high diagnostic accuracy in various clinical settings including history of myocardial infarction, coronary revascularization and multi-vessel diseases and could be used to assist diagnosis in patients suspected of having coronary artery disease.

OP-612

Diagnostic Performance of Artificial Neural Network for the localization of coronary artery disease

H. Shimoyama, S. Nakayama, Y. Kotake, S. Shimamoto, R. Futai; Itami City Hospital, Itami, JAPAN.

Aim: The purpose of this study was to evaluate segmental analysis of stress 99mTc-Sestamibi scintigraphy for the diagnosis and localization of coronary artery disease (CAD) using an artificial neural network (ANN) **Materials and Methods:** A total of

51 patients with CAD were studied with myocardial perfusion imaging(MPI) and coronary computed tomography angiography(CCTA). Automatic processing was carried out using ANN to obtain area of ischemia and Summed stress score (SSS) values based on the 17-segment model in the left anterior descending artery (LAD), left circumflex coronary artery (LCX) and right coronary artery (RCA) lesion. SSS more than 10% is defined ischemia. CCTA stenosis more than 50% is defined significant. We compared the coronary arterial territories diagnosis of SSS with that of ANN using CCTA as a standard of reference. **Results:** In LAD lesion, ANN showed a lower specificity than its SSS values (73vs 92%, p=0.062). In RCA lesion, ANN showed a higher specificity than its SSS values (86vs 83%, P=1.00). But difference between ANN and SSS in sensitivity and specificity for myocardial ischemia of LAD, LCX and RCA area were not significant. **Conclusion:** Although the coronary artery localization diagnosis of ANN was similar to that of SSS, ANN showed higher specificity than SSS in RCA and lower one in LAD lesion. Using ANN may contribute to lower false positive diagnosis rate in inferior ischemia patients with soft tissue attenuation artifacts, but not in LAD lesion.

Methods for reducing 'halo' scatter artefact in Ga-68 PSMA PET/CT and PET/MRI

T. Sanderson, B. A. Thomas, S. Wan, J. C. Dickson; Institute of Nuclear Medicine, University College London Hospital, London, UNITED KINGDOM.

Background: Ga-68 PSMA PET images are susceptible to 'halo' scatter artefacts, where regions with high uptake such as the bladder and kidneys appear surrounded by a photopenic region. This is caused by an over-correction for scattered photons, and is prominent for Ga-68 due to the presence of a 1077 keV prompt gamma photon emission. In this study, methods for dealing with this artefact have been explored for images acquired on three scanners; Siemens mMR PET/MRI, GE D710 PET/CT, and GE DVCT PET/CT. **Methods**: Images were analysed for seven patients who received both PET/CT and PET/MRI Ga-68 PSMA imaging on the same day, and four additional patients who only received PET/MRI imaging. If an artefact was present, the image was re-reconstructed without scatter correction. Five mMR patient studies affected by the artefact were also reconstructed offline using e7 tools software. Multiple reconstructions were carried out with varying maximum scatter fractions

(MSF) (20-75%) reduced from the default 75%. Artefact severity was quantified at each MSF by drawing a 2D profile over the bladder on a transaxial slice. The bladder-to-background ratio was measured for three concentric regions surrounding the bladder (inner, central, outer). This was expressed as a percentage of the 'true' bladder-to-background ratio, defined using the default 75% MSF image and outer region. **Results**: The artefact was present on 3/3 of the DVCT images, 7/11 of the mMR images, and 0/4 of the D710 images. Reconstructions with no scatter correction removed the artefact in all cases, but resulted in noisy images which are no longer quantitatively accurate. Reducing the maximum scatter fraction reduced the severity of the artefact at the cost of increased scatter remaining in the image. For 4/5 patients, a 50% MSF gave the closest result to the 'true' bladder-to-background ratio, with an average across all regions and patients of 87% of the true ratio. For the remaining patient the best MSF was 30%. **Discussion/Conclusion**: 'Halo' artefacts were observed for studies on the GE DVCT and Siemens mMR, but not for the GE D710, indicating an improved scatter correction. The artefact can be removed by reconstructing without scatter correction, but results in noisy, non-quantitative images. For the mMR, improvements can be made by reducing the maximum scatter fraction, with best results found at 50%.

OP-615

NEMA NU 2-2007 Performance Characteristics of GE Signa Integrated PET/MR: Impact of Using Different PET Isotopes

P. Caribé[1,2], M. Koole[3], S. Vandenberghe[1], T. Deller[4], K. van Laere[3]; [1]Medical Imaging and Signal Processing – MEDISIP, UZGhent; IMEC, Ghent, BELGIUM, [2]National Council for Scientific and Technological Development – CNPq, São Paulo, BRAZIL, [3]Division of Nuclear Medicine – UZ/KU, Leuven, BELGIUM, [4]General Electric Healthcare, Waukesha, WI, UNITED STATES OF AMERICA.

The aim of this study is to assess the impact of using different PET isotopes for the NEMA NU 2-2007 performance evaluation of the GE Signa integrated PET/MR. For this purpose, NEMA NU 2-2007 performance measurements for characterizing spatial resolution (SR), image quality (IQ), noise equivalent count rate (NECR) and linearity were performed using both ^{18}F and [68]Ga. **Methods:** For the NEMA NU 2-2007 SR measurements, a ^{18}F and ^{68}Ga point source inside a glass capillary tube was positioned at 1 and 10 cm off-center in the field of view. NECR were measured using a 70-cm-long polyethylene cylinder with a diameter of 20 cm and a line source inserted axially into the cylinder 4.5 cm off-centered filed with 871.01 MBq for ^{68}Ga and 679.54 MBq for [18]F (at first frame start). PET image quality was evaluated using the NEMA IQ phantom with a 4:1 ratio for the hot sphere to background activity concentration. For ^{68}Ga, the background region was filled to 5.0 kBq/mL at scan start time, while for [18]F a background activity concentration of 3.1 kBq/mL was used. For both isotopes, the accuracy of the attenuation and scatter correction was determined from the uniform background and could lung insert regions. **Results:** The SR of ^{68}Ga increased (transaxial) by 3.1%. In the axial direction values increased by 17.8% and 27.9%

(at 1 and 10 cm off-center) respectively as compared to ^{18}F in the axial resolution measurements as compared to [18]F. The ^{68}Ga NECR was slightly lower and at a slightly higher activity concentration than measured for ^{18}F while linearity was not affected by the use of different isotopes. In terms of image quality, the average lung residual error was lower than the 3% for the both isotopes. **Conclusion:** NEMA NU 2-2007 performance measurements using ^{18}F and ^{68}Ga resulted in substantially different system characteristics, specifically in terms of SR and recovery coefficients of the IQ measurements. This is due to the anisotropic higher positron range of ^{68}Ga compared to ^{18}F, with the highest positron range aligned with the main magnetic field and thus affecting the axial more than transaxial resolution. NECR differences between the two isotopes can be explained by the lower positron branching factor of ^{68}Ga and the additional 1.077 MeV gamma emission for 3.2% [68]Ga decays, which leads to additional block business and scattering into the energy window generating additional randoms or scatter.

OP-616

Influence of ignoring bone attenuation in standard PET/MRI of carotid plaques

I. Rausch[1], J. Cal-Gonzalez[1], D. Beizke[1], A. Haug[1], X. Li[1], M. Fenchel[2], T. Beyer[1]; [1]Medical University of Vienna, Vienna, AUSTRIA, [2]Siemens Healthcare GmbH, Erlangen, GERMANY.

Aim: Evaluation of the influence of ignoring bone in standard attenuation correction (AC) in positron emission tomography/magnet resonance imaging (PET/MRI) on standardized uptake values (SUV) of carotid plaque lesions located at the carotid bifurcation. **Methods:** Up to date eleven patients, who underwent a 68-Ga PENTIXAFOR PET/MRI examination (Biograph mMR, Siemens Healthcare) were included in this ongoing study. PET data was reconstructed on a 344x344 matrix using an OSEM algorithm with point spread function correction. AC was based on either the standard Dixon-AC and a model-based AC (non-commercial prototype software, Siemens Healthcare) that inserts spatially-variant bone information (skull and cervical vertebra) into the Dixon-AC. Plaque lesions near the carotid bifurcation were delineated manually on T2-weighted TSE MR images with a pixel size of 0.6x0.6 mm by an experienced radiologist and volumes-of-interest (VOI) were copied to the respective PET images (Hybrid3D v2.0 beta, Hermes Medical, Sweden). SUVs of the maximum (SUVmax) and mean (SUVmean) pixel values were extracted from all VOIs. We report relative differences in SUV between Dixon-AC and model-based AC PET. Significant differences were tested using a paired Wilcox test considering p<0.05 as statistically significant. **Results:** In total 22 plaque lesions were delineated on MRI. On average (±SD), an underestimation of 0.5 ± 0.6% (p<0.001) and 0.4 ± 0.6% (p<0.001) was found for SUVmax and SUVmean, respectively. **Conclusion:** Ignoring bone in standard DIXON-based AC resulted in statistically significant but clinically negligible underestimation of SUV values in carotid plaques located near the carotid bifurcation in 68-Ga PENTIXAFOR examinations.

OP-617

ZTE-based attenuation correction in head and neck PET/MRI

R. de Laroche[1,2], M. Khalifé[3], D. Bequé[4], B. Sgard[1,2], F. Pérez-Garcia[3], M. Soret[1], M. Habert[1,2], F. Wiesinger[4], A. Kas[1,2]; [1]Groupe Hospitalier Pitié-Salpêtrière, Paris, FRANCE, [2]Université Paris 6 UPMC, LIB Inserm U1146, Paris, FRANCE, [3]Institut du Cerveau et de la Moelle épinière (ICM), CNRS UMR 7225 - Inserm U1127 - Université Paris 6 UPMC UMR S1127, Paris, FRANCE, [4]GE Global Research Center, Munich, GERMANY.

Aim: Attenuation correction (AC) remains a major issue in head and neck PET/MR. In this study, we applied a Zero Echo Time (ZTE)-based AC map to account for bone attenuation in this area, and explored a new AC map derived from the combination of ZTE-based and Dixon-based AC maps. **Materials and Methods**: Seven patients underwent a PET/MR scan (SIGNA PET/MR, GE Healthcare) for maxillofacial oncology 1 hour after injection of 3.7 MBq/kg of ^{18}F-FDG. PET/MR acquisition was centered at the cervical region. The available MR-based AC method consists of a two-point Dixon MRI (Dixon-AC) that generates an AC map containing 3 tissue classes: fat, soft tissue and air. In addition to routine MRI sequences, a ZTE pulse sequence was added to the protocol and used to derive an AC map containing bone (ZTE-AC). The ZTE-based AC map contained three tissue classes: bone, air and soft tissue. A hybrid ZTE and Dixon-based AC map was generated by overlaying bone voxels from the ZTE-based AC map on the Dixon-based AC map. For comparison, a CT-derived AC map was used as reference. PET images were reconstructed with the 4 AC maps using a TOF-OSEM algorithm with all corrections. SUV values (SUVmean, SUVmax) were compared on 145 volumes of interest (VOI, 3cm^3) located in bones (n=39), physiological uptakes in oral cavity (n=37), oropharynx (n=28), nasal fossa/nasopharynx (n=13), pterygoid muscle (n=14) and parotid gland (n=14), and pathological uptakes measured in malignant tumors (n=7). **Results:** The Dixon-AC method underestimated FDG uptake with respect to CT-AC method by -4.3±18.0% for SUVmean and -1.3±15.7% for SUVmax. On the contrary, the ZTE-AC method overestimated considerably SUV measurements (12.6±13.9% for SUVmean, and 13.8±14.0% for SUVmax). ZTE-AC provided AC maps with satisfying mandible segmentation. All the methods mis-segmented air in nasal fossa and upper airways. The percentage of difference of all VOIs with the combined ZTE/Dixon method was improved by approximately 45% compared with Dixon-AC, with 2.4±13.6% and 4.6±14.0% overestimation of SUVmean and SUVmax respectively, compared with CT-AC. Accuracy of FDG uptake in bones was also improved by 74% with the combined AC method compared with Dixon-AC. Tumor metabolism was overestimated by 6.0±11.2%, 15.8±8.6% and 8.5±9.9% respectively by Dixon, ZTE and combined AC methods. **Conclusion:** The hybrid ZTE/Dixon AC method improved PET quantification in head and neck PET/MR, particularly in bone regions (mandible and maxilla). ZTE-AC showed limitation due to partial volume effect in upper airways and sinuses.

OP-618

Joint Hardware and Patient Attenuation Correction for Hybrid PET/MR Imaging

T. Heußer[1], Y. Berker[1,2], M. T. Freitag[1], M. Kachelrieß[1]; [1]German Cancer Research Center (DKFZ), Heidelberg, GERMANY, [2]RWTH Aachen University, Aachen, GERMANY.

Purpose: To jointly estimate external hardware and patient attenuation distributions from the PET emission data in hybrid non-TOF PET/MR imaging. **Materials and Methods:** Attenuation correction (AC) for both hardware and patient is required for accurate PET quantification. In hybrid PET/MR imaging AC is a major challenge since the available MR data cannot directly be transformed into accurate information on the attenuation distribution. MR-based AC (MRAC), as applied in current clinical routine, does not properly account for bone attenuation and neglects attenuation of flexible hardware components such as headphones or flexible body coils. Both effects result in severe activity underestimation, limiting the clinical value of hybrid PET/MR imaging. To avoid these effects, we developed a new reconstruction approach combining ideas of our recently developed reconstruction algorithms MR-MLAA (for emission-based patient attenuation correction using MR prior information) [IEEE TNS 63(5):2443, 2016] and xMLAA (for external hardware attenuation correction) [EJNMMI Physics 4:12, 2017]. The new algorithm, xMR-MLAA, is based on maximum-likelihood reconstruction of attenuation and activity (MLAA), which estimates both attenuation and activity distributions from the PET emission data. First, the attenuation of flexible hardware components is estimated by employing the MLAA attenuation update only outside the patient and table regions. Then, considering the estimated hardware attenuation, the initial patient attenuation map is updated while incorporating MR-based anatomical prior information. The thus-estimated attenuation distribution is refined, performing additional interleaved updates on hardware and patient attenuation. The proposed method was evaluated for three clinical ^{18}F-FDG head scans acquired with a Siemens Biograph mMR. Conventional T1-weighted MR images were used to derive the patient support as well as anatomical prior information on the patient attenuation distribution. CTAC was used as a reference. **Results:** Standard MRAC results in activity underestimation in the brain, caused both by neglecting headphone attenuation and by treating bone as soft tissue during AC. Across three FDG patients included in this study, average brain activity underestimation was 14.8% compared to CTAC. Using xMR-MLAA, bone attenuation information could be accurately recovered while preserving air cavities like the nasal sinuses and the inner ears. Moreover, accurate estimates of the headphone attenuation were obtained. Average brain activity underestimation with xMR-MLAA was 2.8% compared to CTAC. **Conclusion:** We propose a method to jointly estimate hardware and patient attenuation in hybrid PET/MR imaging. The proposed method was shown to significantly reduce activity underestimation for clinical ^{18}F-FDG patient data and can, potentially, be readily included into clinical workflow.

OP-619

Comparison of quality control between PET/MRI and PET/CT systems using NEMA tests

M. Abuqbeitah[1], M. Demir[1], N. Yeyin[1], T. Toklu[2], S. Sezgin[3], H. Çetin[3], K. Sönmezoğlu[4]; [1]Istanbul university, Istanbul, TURKEY, [2]Yeditepe university, Nuclear Medicine Department, Istanbul. TURKEY, [3]epsilon laboratory, Istanbul, TURKEY.

Aim: This work targeted to compare NEMA test results among PET/CT and PET/MRI of the same providing company. **Material & Methods:** This study was carried out over General Electric (GE) Signa PET/MR and GE Discovery PET/CT systems. The rescommended NEMA tests was similarly performed using F-18 radioisotope and NEMA fantom involving Spatial Resolution, Sensitivity, Scatter Fraction/Count Rate Performance, Image Quality as well as the accuracy of correction for count losses and randoms. **Results:** Spatial Resolution results were tabulated below: The Sensitivity of PET/MRI was (22.2 cps/kBq) higher than PET/CT (5.46 cps/kBq). Peak NECR and Scatter Fraction (%) findings of PET/MRI with 17.7 kBq/cc prepared activity was 218 kcps and %43.4 respictively, while the generated values for PET/CT using activity of 27.6 kBq/cc was 137.2 Kcps for peak NECR and %39.1 for scatter fraction. Regarding to image quality, the contrast of hot lesions with 8:1 activity concentartion of PET/MRI was 56, 72, 78, and % 85 while the results were as lower as 52, 54, 70, and 78% for PET/CT. Accuracy of correction for count losses and randoms was also measured inwhich the unaccuracy of PET/MRI and PET/CT was %3.40 and %5.13 respictively. **Conclusion:** PET/MRI system seems relatively superior to PET/CT in terms of performance characteristics and image quality.

Optimisation of penalized likelihood estimation reconstruction on a digital time-of-flight PET-CT scanner for four different PET tracers

E. Lindström[1,2], A. Sundin[1,3], C. Trampal[3], L. Lindsjö[3], J. Sörensen[1,3], M. Lubberink[1,2]; [1]Department of Surgical Sciences/Nuclear Medicine & PET, Uppsala University, Uppsala, SWEDEN, [2]Medical Physics, University Hospital, Uppsala, SWEDEN, [3]PET Centre, University Hospital, Uppsala, SWEDEN.

Introduction: Resolution and quantitative accuracy of PET images are highly influenced by reconstruction method. Penalized likelihood estimation methods allow for fully convergent iterative reconstruction, leading to a higher image contrast while limiting noise compared to the current clinical standard ordered subsets expectation maximisation (OSEM). Block-sequential regularized EM (BSREM) was compared to OSEM in this study. Various strengths of noise penalization factor β were tested along with scan duration with the aim to optimise the performance and clinical use of BSREM for four tracers, both in quantitative terms and in a qualitative observer study. **Methods**: Data from clinical whole-body PET-CT scans with ^{68}Ga-DO-TATOC, ^{18}F-FDG, ^{18}F-fluoride and ^{11}C-acetate acquired on a digital time-of-flight PET-CT (Discovery MI, GE Healthcare) were included. Each scan (n_{total}=47) was reconstructed using BSREM (Q.Clear) with β 133, 267, 400 and 533, and OSEM (3 iterations, 16 subsets, 5 mm Gaussian filter) with point spread function recovery, for different acquisition time/bed. A reference VOI was placed in healthy liver tissue and lesions were delineat-

ed employing a 41% threshold of the maximum voxel value. Noise, signal to noise ratio (SNR), signal to background ratio (SBR) and maximum standardized uptake value (SUV_{max}) were analysed. A blinded image quality evaluation of ^{18}F-FDG reconstructions, rating different aspects, performed by experienced nuclear medicine physicians complemented the analysis. **Results:** The lowest levels of noise were reached with the highest β resulting in the highest SNR and in turn the lowest SBR. Noise equivalence to OSEM was found with β 400 (^{68}Ga-DOTATOC, ^{18}F-FDG, ^{18}F-fluoride) and β 267 (^{11}C-acetate), combined with a significant increase of SUV_{max} (24%, 12%, 23% and 19%), SNR (27%, 23%, 12% and 30%) and SBR (24%, 13%, 25% and 18%) compared to OSEM. Decreasing acquisition time with BSREM, by 1 or 0.5 min/bed, reduced SNR although it remained higher or equal to OSEM at full acquisition durations for all tracers at their optimal β, and gave only small differences of SUV_{max}. The observer evaluation resulted in similar scores between reconstructions, β 267 was rated highest regarding overall judgement, contrast and tumour detectability, while β 400 obtained the highest mean score and achieved a better score than OSEM concerning noise, liver background and tumour detectability. **Conclusions:** BSREM reconstruction resulted in a tracer-dependent increase in tumour SUV_{max}, SNR and SBR compared to OSEM at matched levels of noise. Observers' evaluation and semi-quantitative measures coincides and BSREM performed better than OSEM in terms of tumour detectability.

OP-631

Bayesian Penalized Likelihood Image Reconstruction (Q.Clear) in 82Rb Cardiac PET: Impact of Count Statistics

N. Christensen, L. P. Tolbod; Dept. Nuclear Med. & PET-Centre, Aarhus University Hospital, Aarhus, DENMARK.

Aim: Q.Clear reconstruction is expected to improve detection of perfusion defects in cardiac PET due to the high degree of image convergence and effective noise suppression. However, 82Rb (T½=76s) possess a special problem, since count statistics vary significantly not only between patients but also during the acquisition. Image smoothening imposed by the noise penalty (beta) of Q.Clear may vary significantly between patients leading to exaggeratedly smoothened images with poor contrast in some patients and very noise images in others. In this study, we illustrate the effect of varying count statistics using a cardiac PET phantom as well as a selection of clinical patients referred for 82Rb cardiac PET. **Methods:** The study consistent of 3 parts: 1) A thorax-cardiac phantom was scanned for 10 minutes after injection of 1110 MBq 82Rb. Frames at 3 different times after infusion were reconstructed to yield images with total number of prompts (TP) ranging from 4 to 40 MCnts. Contrast of defect-to-LV and LV-to-cavity were characterized at a range of beta factors. 2) Body Surface Area (BSA) and TP in static frames 2.5-5 min post 82Rb infusion (1110 MBq) was extracted from 75 consecutive clinical 82Rb PET scans. 3) Static and dynamic images from a set of 7 patients (BSA: 1.6-2.2 m2) referred for 82Rb cardiac PET was analyzed using a range of beta factors. Results were compared to the institution's standard clinical

practice reconstruction protocol. All scans were performed on GE DMI Digital-Ready or D690 PET/CT. **Results:** 1) Contrary to the standard images, contrast of defect-to-LV and LV-to-cavity was found to depend highly on the number of TP when using Q.Clear. 2) TP in patient scans (static) could be approximated as a linear function of BSA (TP=-5e7xBSA+2e8, R2=0.7, range TP: 20-100 MCnts, BSA: 1.5-2.5 m2). 3) Optimum performance was found at beta factors ranging of 25-100. Interestingly, MBF measurements were consistent with standard protocol results within 10% at beta factors ranging from 10-100, even though, the smoothing resulting from the noise penalty varied highly from first passage (high counts, low smoothing) to the late uptake phase (low counts, high smoothing). **Conclusion:** The Q.Clear reconstruction algorithm can be used for the 82Rb cardiac PET. For a fixed administered 82Rb dose of 1110 MBq, the optimal range of beta factors is 25-100. However, the patient specific optimal beta factor seems to depend on both administered dose and patient BSA.

OP-632

Determining the Minimum Administered Activity for Tumour FDG PET/CT Imaging that satisfies EARL Specifications, and Investigation of Bayesian Penalised Likelihood Reconstruction

T. Sanderson, J. Dickson; University College London Hospital, London, UNITED KINGDOM.

An EARL procedure has been followed to determine the minimum administered activity (MBq.min.bed^{-1}.kg^{-1}) and OSEM-TOF reconstruction parameters that satisfy EARL specifications for activity concentration recovery coefficients (RCs) and image noise in FDG PET/CT imaging. A similar procedure is also performed for a Bayesian Penalised Likelihood (BPL) reconstruction. A NEMA-IQ phantom was filled, obtaining a 10:1 sphere-to-background ratio and representing a 75 kg patient administered with 300 MBq FDG at 1 hour post-injection. The phantom was imaged for 5 min.bed^{-1} in list mode on a GE D710 system. The data was reconstructed with OSEM-TOF (2i, 24s) with a range of post-reconstruction smoothing filters (5-8.5 mm). Mean (A50%) and maximum RCs for all spheres (10-37 mm) were determined. For two chosen filters the data was re-sampled into five additional reduced min.bed^{-1} images and identically reconstructed. The mean background coefficient of variation (CoV) in each image was fitted against the min.bed^{-1} using a power law. A similar procedure was performed for a BPL reconstruction (β=400). OSEM-TOF reconstructions with an 8.5 mm filter resulted in all RCs within EARL specifications. The minimum activity to meet the maximum EARL specified CoV of 15% was 4.8 MBq.min.bed^{-1}.kg^{-1}. Reconstructions using a 6.4 mm filter resulted in increased RCs, and for two spheres were higher than the maximum specifications. Images were noisier, and the minimum required activity was 10.5 MBq.min.bed^{-1}.kg^{-1}. BPL reconstructions demonstrated significantly increased RCs (0.88-0.98 for mean A50%) with a relatively flat recovery curve. Image noise was comparable to OSEM-TOF with a 6.4 mm filter, with a minimum required activity of 11.4 MBq.min.bed^{-1}.kg^{-1}.

Edge enhancement artefacts were observed, as PSF model-ling is incorporated. For OSEM-TOF reconstructions an activity of 4.8 MBq.min.bed^{-1}.kg^{-1} can meet EARL specifications for RCs and noise. This is significantly less than the stated EANM min-imum of 14 MBq.min.bed^{-1}.kg^{-1} (PET bed overlap <30%). If 370 MBq is administered for a 75 kg patient, this corresponds to <1 min.bed^{-1}, or an 8 minute WB scan (alternatively 120 MBq ad-ministered for 3 min.bed^{-1}). The maximum EARL specifications for RCs are lower than modern PET/CT systems are capable of to ensure equivalent image quality in multi-centre trials. The higher RCs obtained with a 6.4 mm filter may be preferable, and the required minimum activity of 10.5 MBq.min.bed^{-1}.kg^{-1} is still significantly less than the EANM minimum. The BPL recon-structions result in much greater RCs, and image noise can be comparable to OSEM-TOF.

OP-633

Investigation into Optimal PET-CT Image Reconstruction for the Detection and Quantification of Inflammation and Infection Associated with Implanted Cardiac Devices

Y. Bouchareb[1,2], J. Thomas[2], G. Delanerolle[1], H. Jan[1], N. Hartman[1], A. Haroon[1]; [1]Barts Health NHS Trust, London, UNITED KINGDOM, [2]Queen Marys University, London, UNITED KINGDOM.

Purpose: To optimise and assess PET image reconstruction for the detection, localization and quantification of metabolically active foci of infection/inflammation affecting Cardiac Implant-ed Electronic Devices (CIEDs). **Materials and Methods**: An an-thropomorphic torso-phantom with balloons filled and sealed with FDG solution was used to mimic the inflammation and infection around the myocardium insert. The balloon-to-myo-cardium (40.2 KBq/mL) ratio was 10:1 (total activity was 44 MBq). A metal object was placed on top of the torso phantom where the cardiac insert is situated to replicate the CIED and its metal artefacts. A population of 10 patients (6 males and 4 females: age range of 45 -77 years) with CIEDs was also used to assess the value of TOF PET reconstruction to accurately quantity the inflammation/infection associated with CIEDs. Phantom exper-iments and patients were scanned on the Gemini TF-TOF 64 slice PET/CT Philips scanner. To optimise image reconstruction, three different reconstructions: List-mode OSEM-TOF using 3 iterations and 33 subsets (Recon1), List-mode OSEM-TOF using 3 iterations and 20 subsets (Recon2) and non-TOF 3D-RAMLA (Recon3) and were performed. To assess the effect of relaxation parameters (filter sizes), four different relaxation parameters (1, 0.7, 0.6 and 0.5) were applied with each reconstruction. A to-tal of 12 reconstructions were compared on phantom images. Activity line profiles (ALP), SUVmax, Target-to-background ratio (TBR) and Noise were used to analyse phantom and patients reconstructed images. **Results**: On phantom experiments, ALP extracted through balloons diameters in transverse slices in-dicated an improvement 7%, 13% and 21% in Recon1 recon-structed balloons diameters using a relaxation parameter of 1 over Recon2, Recon3, respectively (relaxation parameter of 1 was adopted for patient images). On this patient population, SUVmax was 4.3, 3.1 and 3.6 on wire and was 2.1, 1.9 and 1.6 on

the pacemaker for Recon1, Recon2 and Recon 3, respectively. This reflects a better indication of the inflammation/infection around the wires was detected on Recon1 images. The TBR cal-culated on the wire was 2.2, 1.1 and 1.5 and on the pacemaker was 1.4, 1.1 and 0.9 for Recon1, Recon2 and Recon3, respective-ly. The noise was in favour of Recon1 and Recon2 over Recon3. **Conclusion**: TOF FDG-PET/CT image reconstruction using 3 it-erations and 33 subsets with a relaxation parameter of 1 proved to be the most suitable reconstruction method for better detec-tion and quantification of inflammation/infection around the wire and pacemaker in patients with CIEDs.

OP-634

SMART(SiMulAtion and ReconsTruction) PET: An efficient PET simulation-reconstruction tool

E. Pfaehler, R. Boellaard, J. De Jong; UMCG Groningen, Groningen, NETHERLANDS.

Purpose: PET simulations are useful for development and per-formance evaluation of e.g. segmentation methods and quan-titative uptake metrics. Several PET simulation-reconstruction packages exist but most are either computationally demanding or lack the implementation of time-of-flight (TOF) and resolu-tion modeling (RM). The aim of this study is to develop and vali-date a new PET simulation-reconstruction tool, SMART-PET, that includes state-of-the-art features such as TOF and RM. **Meth-ods:** The simulation-reconstruction tool allows the generation of 3D PET images based on an analytical simulator (forward projection). As input it requires 3D images representing activi-ty and attenuation coefficient distributions. SMART-PET allows the user adjustable TOF, RM, noise/counts, scatter and random fractions, blurring, iterative deconvolution and use of different matrix/voxel sizes. Moreover, random spatial shifts can be in-cluded to simulate effects of repositioning patients. To validate our simulator a 3D list-mode scan of 60 min was acquired on a Siemens mCT Biograph using the NEMA NU2 image-quality phantom filled such to obtain sphere-to-background ratios of 10 and 0.5. Ten statistically equivalent replicates, representative for 30, 60, 120 and 300s scan durations, were extracted from the list-mode acquisition and reconstructed using various iterative reconstruction methods (TOF on/off, RM on/off) and matrix siz-es(256x256, 400x400). All corrections necessary for obtaining quantitative PET data, such as e.g. attenuation, scatter etc, were included. Equivalent images were generated using SMART-PET. The statistically equivalent images (measured and simulated) were further processed to obtain mean and variance images for comparison. Moreover, SUV recovery coefficient (RC) and back-ground noise (COV,%) derived from simulated and actual data were compared. **Results:** Images obtained using SMART-PET were comparable to actual phantom data. Change in counts, reconstruction settings and RM resulted in comparable chang-es in image characteristics between simulated and actual data. Moreover, variation of TOF showed variation in background noise following theoretically expected SNR changes. Sphere RCs as function of sphere size in the simulated data agreed within 12% with those found in the actual phantom scans. Regarding

mean and variance images a difference of around 2% (mean) and around 20% (variance) was found between simulated and actual image in the spheres. **Conclusion:** The SMART-PET tool simulates PET images with comparable image characteristic as those seen in actual phantom data and allows fast simulation of PET data with different settings. Small discrepancies found can be resolved by more closely matching simulation settings, e.g. scatter/randoms fractions, with those seen in actual PET data using a specific calibration process.

OP-635

Comparison of a statistical analysis method and a visual assessment of Monte Carlo based SPECT reconstruction concerning liver metastases in ^{111}In-octreotide diagnosis

E. Wikberg[1], M. van Essen[2], T. Rydén[1], J. Svensson[3], P. Gjertsson[2], P. Bernhardt[1]; [1]Department of Radiation Physics, Gothenburg, SWEDEN, [2]Department of Nuclear Medicine, Gothenburg, SWEDEN, [3]Department of Oncology, Gothenburg, SWEDEN.

Aim: This work aims to accomplish an increase in diagnostic accuracy of ^{111}In-octreotide SPECT images. This is done by improving image quality through implementation of Monte Carlo (MC) based OSEM reconstruction and by application of an analysis technique called nNUFTI. **Materials and Methods:** The nNUFTI method, developed at Sahlgrenska University Hospital, is focused on the concept of homogeneity and is a statistical approach with the assumption that uptake foci distribution differs between livers with and without tumour involvement. The distribution of the normalized number of uptake foci is plotted against a threshold index (ThI) and the quantitative measure used is ThI at 25% of maximum uptake foci. Tumour involvement will shift the curves towards higher ThI. We have previously shown that in a group of 53 randomly selected ^{111}In-octreotide tumour negative patients (iterative reconstruction with attenuation correction, IRAC OSEM) nNUFTI was able to separate the group of patients (n=40) that stayed healthy in a three-year follow-up from the group of patients (n=13) that had emergent liver tumours (p<0,01). 5 out of these 13 patients were clearly above the normal group in ThI. In the present study, the patient material has been reconstructed using Sahlgrenska Academy Reconstruction Code (SARec) to improve image quality. SARec is a MC based iterative OSEM reconstruction method where MC simulations are used in the forward projection. An observer (a trained nuclear medicine specialist) has reviewed 15 patients (of which 9 had emergent liver metastases) once again using reconstruction with IRAC OSEM and using SARec. Criteria evaluated were liver metastases yes (1) or no (0) with confidence level 1-3 (1-low/uncertain, 2-moderate/probable and 3-high/certain). The observer was aware that some patients were found to have emergent liver metastases. **Results:** The observer could not locate any liver metastases in any of the patients, neither using conventional reconstruction nor using SARec. Confidence level was higher (mean=2,7) for IRAC OSEM than for SARec (mean=1,9). **Conclusion:** Although biased (the observer knew that nNUFTI had identified patients with ThI above normal) the observer could not locate any liver metastases. Higher image quality with SARec did not change the visual outcome but lowered the observer's confidence level concerning lack of metastases. This shows the importance of and need for a quantitative measure like nNUFTI. Future plans include nNUFTI analysis using SARec and improvement of the visual quality of SARec images to increase confidence levels.

OP-636

A post-acquisition normalization to co-analyze textural features from multi-center PET images

F. Orlhac[1], S. Boughdad[1,2], C. Nioche[1], J. Alberini[2], M. Soussan[1,3], I. Buvat[1]; [1]IMIV, CEA, Inserm, CNRS, Univ. Paris-Sud, Université Paris-Saclay, CEA-SHFJ, Orsay, FRANCE, [2]Department of Nuclear Medicine, Institut Curie-René Huguenin, Saint-Cloud, FRANCE, [3]Department of Nuclear Medicine, Assistance Publique - Hôpitaux de Paris, Avicenne Hospital, Bobigny, FRANCE.

Purpose: Intratumor heterogeneity characterized by PET textural features (TF) is increasingly used in retrospective studies. Yet, several studies demonstrated that TF values are affected by the acquisition and reconstruction parameters. We proposed a method to standardize TF measured in PET. **Methods:** Patients with breast non-metastatic lesions were included. In department (dpt) A, 110 patients were scanned using a Gemini TOF PET/CT scanner (Phillips) with a list-mode iterative reconstruction algorithm (BLOB-OS-TF, 2 iterations, 33 subsets, voxel=4x4x4 mm3). In dpt B, 69 patients underwent a PET/CT using a GE Discovery LS Scanner (GMS), reconstructed with OSEM algorithm (2 iterations, 24 subsets, voxel=2.7x2.7x3.3 mm3). For each patient, VOIs of 23 ml were set in the liver, spleen, lung, muscle and healthy breast tissue. For each VOI, we built a vector of biomarkers composed of 6 TF: Homogeneity, Entropy, SRE, LRE, LGZE, HGZE. To characterize the similarity between two biomarker vectors measured in two patients, we computed the component-wise ratio between the two vectors and calculated the standard deviation over the 6 ratios, called SDM as Standard Deviation Metric. If the vectors are homothetic, SDM is 0. We used this metric to measure the similarity between biomarker vectors in different patients. We computed the averaged SDM in patients from dpt A only, in patients from dpt B only and from pairs of patients consisting of 1 from dpt A et 1 from dpt B. We compared the values for TF calculated from the original images (M1), from the images resampled to the same voxel size (2x2x2 mm3, cubic B-spline interpolation) (M2), and using M2 then dividing each TF by the median TF measured in the liver of all patients of each department separately (M3). **Results:** In spleen, we found that SDM was 0.12±0.08 for patients from dpt A, 0.12±0.08 for patients from dpt B for M1, and 0.21±0.11 between patients from dpts A and B. This suggests that the spleen TF vector is different between the two dpts (inter-center variability). Between patients from dpts A and B, spleen SDM was 0.16±0.10 for M2 and 0.14±0.09 for M3. The same trend was observed in the other four tissues. **Conclusion**: Calculating TF using the same voxel size is useful but not sufficient to remove the multi-center variation of TF. Additional normalization using a patient-indepen-

dent measurement in a reference tissue (here the median liver TF) further reduces multi-center variability. Such a standardization could facilitate multicenter studies.

OP-637

Comparison of Tumor Heterogeneity Assessed with Textural Parameters in ^{68}Ga-PSMA PET/CT and ^{177}Lu-PSMA SPECT/CT in Patients with Metastatic Prostate Cancer

L. Schwarte[1], L. Thomas[1], E. Eppard[1], M. Meisenheimer[1], C. Weiss-Wichert[2], M. Essler[1], R. A. Bundschuh[1]; [1]Department of Nuclear Medicine, Universitätsklinikum Bonn, Bonn, Germany, Bonn, GERMANY, [2]Mediso GmbH, Münster, GERMANY.

Purpose: Tumor heterogeneity in PET/CT assessed by textural parameters is gaining importance as prospective and predictive feature for multiple clinical applications. Especially in theranostics, PET and SPECT images are often performed in the same patient. Therefore, the aim of this study was to compare, if tumor heterogeneity assessed in PET/CT and SPECT/CT imaging is correlating to each other in the same lesion. This was evaluated in phantom and patient data. **Subjects and Methods:** A self-built heterogeneity phantom as well as 37 patients with metastasized prostate cancer who underwent a peptide receptor radionuclide therapy (PRRT) received a ^{68}Ga-PSMA PET/CT before and ^{177}Lu-PSMA SPECT/CT directly after each therapy cycle. Some patients only had one cycle, most had two or three, and one patient received four cycles. The variety in cycles depends on the tolerance and the survival of the patients. Both PET/CT and SPECT/CT images were processed with Interview™ Fusion software (Mediso Medical Imaging Systems). The biggest lesions were selected and manually marked in both images. Consequently 36 textural features, including deviation, entropy and different emphases were calculated. In addition, conventional parameters as tumor mean and max SUV, and tumor volume were tested as well. Results were compared using Bland-Altman Plots. **Results:** Overall, 188 metastases from 37 patients were analyzed. In Bland-Altman Plots it was shown that for the majority of the 40 parameters there is no direct comparability between PET/CT and SPECT/CT values. Using the 95% confidence interval, the best variables could be identified. Long Zone Low Grey Level Emphasis had a high accordance. 94.7% of the data were contained in 95% confidence interval. For the Short Zone Low Grey Level Emphasis it was 32.8%, 32.3% for the volume, 34.9% for TLG, 23.8% for maximum and 21.7% for the mean. Variables such as entropy which are frequently used in tumor heterogeneity have low accordance values. Only 12.2% of the entropy data are contained in the 95% confidence interval. Intensity Variation and Zone Length Non Uniformity only have results of 4.2%. Different values were found for the phantom, in which a high correlation (p<0.01) was found for the different heterogeneity parameters. **Conclusion:** This study shows, that in contrast to data obtained by phantoms, in real patients tumor heterogeneity in PET/CT and SPECT/CT is not correlating. The importance and necessity of retrospective studies looking in to the clinical value of tumor heterogeneity obtained in SPECT/CT images is still given.

OP-638

First radiofluorination of LLP2A and In-vivo PET Imaging of α4β1 integrin-expressing tumors in mice

D. Perrin[1], A. Roxin[1], C. Zhang[2], K. Lin[2], F. Benard[2]; [1]University of British Columbia, Vancouver, BC, CANADA, [2]BC Cancer Research Centre, Vancouver, BC, CANADA.

Objectives: The peptidomimetic, LLP2A, is a specific, high-affinity ligand for $\alpha_4\beta_1$ integrin receptors. Our objective is to provide the first radiosynthesis of an F-18 labeled LLP2A-RBF$_3$ conjugate and investigate PET images in mice. Previously, various LLP2A conjugates were evaluated *in vivo* as imaging agents yet to date there has been no report of an ^{18}F-labeled LLP2A. Notably, F-18 is often preferred for PET imaging, yet its short half-life and general inactivity under aqueous conditions challenges peptide labeling. A simple method for labeling complex biomolecules can be achieved in a single, aqueous step by isotope exchange (IEX) on an organotrifluoroborate to readily capture ^{18}F-fluoride. **Methods**: PEGylated LLP2A was synthesized by standard solid-phase peptide synthesis to afford a C-terminal amide-linked PEG spacer terminated with an azide for eventual click conjugation to an alkyne-modified organotrifluoroborate. Following click-conjugation, the LLP2A-BF$_3$ bioconjugate was HPLC purified and aliquotted. For labeling, NCA ^{18}F-fluoride ion (~37 GBq) was trapped on a QMA cartridge and eluted into a solution of buffered aqueous DMF containing the LLP2A-BF$_3$ and heated for 15 min at 80-85 degrees. Following quench per standard protocols, radiochemically pure radiotracer was isolated in 50% ethanol following Sep-Pak desalting. Mice with xenograft tumors were imaged with standard blocking controls following injection of 3.7 MBq. Following imaging by PET in accord with standard humane use protocols, mice were sacrificed for organ dissection and biodistribution analysis. **Results**: Radiochemical yields were moderate (11%) with high specific radioactivities of 148 GBq/umol (n=5). ^{18}F-RBF$_3$-LLP2A accumulated in tumors with tumor uptake values of 10≠2%ID/g along with similar uptake values for gut and liver. Blocking controls with excess LLP2A demonstrated specific tumor uptake. Bone uptake was approximately 5%ID/g however bone uptake was blockable consistent with high $\alpha_4\beta_1$ integrin expression in bone marrow. **Conclusion**: In conclusion, we report the first labeling of LLP2A with NCA ^{18}F-fluoride ion. This is facilitated by isotope exchange in aqueous conditions by use of an organotrifluoroborate prosthetic group that affords efficient user friendly single-step labeling. Image data is promising as tumor uptake is high and T:NT ratios are high. These promising results highlight the use of RBF$_3$s for convenient labeling while indicating that other derivatives with longer PEG linkers may minimize gut/liver uptake.

OP-639

[^{18}F]fluorination of biorelevant arylboronic acid pinacol ester scaffolds synthesized by convergence techniques

G. S. Clemente[1], T. Zarganes-Tzitzikas[2], I. F. Antunes[1], A. Dömling[2], P. H. Elsinga[1]; [1]Department of Nuclear Medicine and Molecular Imaging, University Medical Center Groningen, University of Groningen, Groningen, NETHERLANDS, [2]Department of Drug Design, University of Groningen, Groningen, NETHERLANDS.

Aim: The development of small molecules through convergent multicomponent reactions (MCR) has been boosted during the last decade due to the ability to synthesize, virtually without any side-products, numerous small drug-like molecules with several degrees of structural diversity.[1] The association of positron emission tomography (PET) labeling techniques in line with the "one-pot" development of biologically active compounds has the potential to become relevant not only for the evaluation and characterization of those MCR products through molecular imaging, but also to increase the library of radiotracers available. Therefore, since the [18F]fluorination of arylboronic acid pinacol ester derivatives tolerates electron-poor and electro-rich arenes and various functional groups,[2] the main goal of this research work was to achieve the 18F-radiolabeling of several different molecules synthesized through MCR. **Materials and Methods:** [18F]Fluorination of boronic acid pinacol esters was first extensively optimized using a benzaldehyde derivative in relation to the ideal amount of Cu(II) catalyst and precursor to be used, as well as the reaction solvent. Radiochemical conversion (RCC) yields were assessed by TLC-SG. The optimized radiolabeling conditions were subsequently applied to several structurally different MCR scaffolds comprising biologically relevant pharmacophores (e.g. β-lactam, morpholine, tetrazole, oxazole) that were synthesized to specifically contain a boronic acid pinacol ester group. **Results:** Radiolabeling with fluorine-18 was achieved with volumes (800 µl) and activities (≤ 2 GBq) compatible with most radiochemistry techniques and modules. In summary, an increase in the quantities of precursor or Cu(II) catalyst lead to higher conversion yields. An optimal amount of precursor (0.06 mmol) and $Cu(OTf)_2(py)_4$ (0.04 mmol) was defined for further reactions, with DMA being a preferential solvent over DMF. RCC yields from 15% to 76%, depending on the scaffold, were reproducibly achieved. Interestingly, it was noticed that the structure of the scaffolds, beyond the arylboronic acid, exerts some influence in the final RCC, with electron-withdrawing groups in the para position apparently enhancing the radiolabeling yield. **Conclusion:** The developed method with high RCC and reproducibility has the potential to be applied in line with MCR and also has a possibility to be incorporated in a later stage of this convergent "one-pot" synthesis strategy. Further studies are currently ongoing to apply this radiolabeling concept to fluorine-containing approved drugs whose boronic acid pinacol ester precursors can be synthesized through MCR (e.g. atorvastatin). **References:** (1) Zarganes-Tzitzikas T. and Dömling A., *Org. Chem. Front.*, 2014, 1(7):834-837; (2) Tredwell M. *et al.*, *Angew. Chem. Int. Ed.*, 2014, 53:7751-7755.

OP-640

Synthesis and Evaluation of a Novel Tetrakis(3-Hydroxy-4-Pyridinone) Ligand for 89Zr-Labeling of Antibodies for ImmunoPET

C. Buchwalder[1], J. Rousseau[2], C. Rodríguez-Rodríguez[1], M. G. Jaraquemada-Peláez[1], C. Orvig[1], P. Schaffer[3,1], F. Bénard[1,2], K. Saatchi[1], U. O. Häfeli[1]; [1]University of British Columbia, Vancouver, BC, CANADA, [2]BC Cancer Agency, Vancouver, BC, CANADA, [3]TRIUMF, Vancouver, BC, CANADA.

Purpose: Zirconium-89 (89Zr) is a prominent radionuclide for antibody-targeted positron emission tomography (immunoPET) imaging. Desferrioxamine B (DFO) is currently the most widely used 89Zr-chelator, however there is concern that its hexadentate chelation may not be sufficiently stable in vivo. This has spurred recent efforts towards alternative 89Zr-ligands, which prevent the release of osteophilic 89Zr. In this study, we synthesized and evaluated a novel octadentate tetrakis(3-hydroxy-4-pyridinone) ligand (THPN) and its bifunctional derivative, as a potentially superior 89Zr-chelator for immunoPET imaging. **Methods:** The acyclic chelator THPN and its bifunctional derivative were synthesized and fully characterized. The Zr^{IV}-complex formation was studied experimentally and computationally and the concentration-dependence of 89Zr-radiolabeling was determined. The 89Zr-THPN stability was assessed in a direct transchelation challenge against DFO, in human serum, as well as in an EDTA challenge, and compared to 89Zr-DFO. The in vivo behavior of 89Zr-THPN was also studied in C57BL/6 mice. We are currently preparing and characterizing chelate-trastuzumab conjugates. Studies to assess the biodistribution and in vivo stability of these immunoconjugates in tumor-bearing mice are underway. **Results:** The chelator THPN quantitatively complexed $89Zr^{4+}$ within 10 min at ambient temperature using 10^{-6} M concentrations of the chelator and formed the monometallic 89Zr-THPN complex. Density functional theory (DFT) calculations indicate a well-ordered octadentate complex structure. A direct transchelation study demonstrated the high stability of 89Zr-THPN, which outperformed 89Zr-DFO. One equivalent of THPN ligand triggered transchelation of $89Zr^{4+}$ from 89Zr-DFO to form the THPN-complex. In contrast, 89Zr-THPN resisted a hundred-fold excess of DFO and did not transchelate. In human serum, the THPN-complex remained 93 ± 2% intact over 7 days. Challenge with a 100-fold excess EDTA did not affect 89Zr-THPN integrity at pH 6–8, and at pH 5 the THPN-complex integrity (41.6 ± 11.1%) greatly exceeded that of 89Zr-DFO, which completely disintegrated. Healthy mice rapidly cleared the 89Zr-THPN complex via urine with no substantial organ uptake. Results from the immunoconjugation of the bifunctional THPN-analogue and subsequent in vivo biodistribution results are expected shortly. **Conclusion:** The octadentate ligand THPN and its bifunctional analogue were synthesized and studied as 89Zr-chelators. THPN quantitatively formed the monometallic 89Zr-complex, which outperformed 89Zr-DFO in a direct transchelation studies. Moreover, mice rapidly excreted the radiocomplex without signs of demetallation. The investigation of the immunoconjugation and biodistribution of the chelate-trastuzumab conjugate is currently underway.

OP-641

Piscidin 1: from an antimicrobial peptide to anticancer peptide, a natural chelator for 64Cu

H. Hong, W. Lu, D. Yang, D. Chen; *University of Michigan, Ann Arbor, MI, UNITED STATES OF AMERICA.*

Purpose: Piscidins (PCD) were the first antimicrobial peptides discovered in vertebrates. Our recent investigation confirmed that one of the family members, PCD-1, possesses two unique properties: it shows decent cancer cell killing efficacy (IC_{50}: 4.8 µM for MDA-MB-231 cells), and it bears a Cu^{2+}-binding motif inside its structure. In this study, we hope to increase the cancer cell selectivity and accumulation of PCD-1, and use PCD-1 as a binding ligand for ^{64}Cu. Methods: A fused peptide containing PCD-1 sequence and another tumor-homing peptide F3 was synthesized and named PCD-1-F3. The cytotoxicity of PCD-1, natCu-PCD-1 (non-radioactive copper), PCD-1-F3, and natCu-PCD-1-F3 was measured in MDA-MB-231 cells and L929 fibroblasts by CCK-8 . Fluorescein was site-specifically introduced onto PCD-1-F3 and PCD-1 to study their interaction with cancerous and normal cells via flow cytometry and confocal fluorescence microscopy. ^{64}Cu-PCD-1-F3 and ^{64}Cu-PCD-1 was injected into MDA-MB-231 tumor bearing mice with serial PET imaging being conducted to examine their tumor accumulating behavior. Biodistribution studies and histological analysis were also carried out. A treatment study (n = 5 per group) was done in MDA-MB-231 tumor-bearing mice by using PCD-1 derivatives (5 mg/kg intravenously every other day for four weeks). Results: Both PCD-1 and PCD-1-F3 showed strong binding for copper, and natCu-PCD-1-F3 had the most potent killing efficacy for MDA-MB-231 cells. None of these PCD-1 derivatives showed significant impact for L929 growth and status. Flow cytometry and fluorescence microscopy both confirmed that the internalization of fluorescein-PCD-1-F3 into MDA-MB-231 cells was significantly stronger than that of fluorescein-PCD-1. ^{64}Cu-PCD-1-F3 was sufficiently stable to be used *in vivo* (<15% ^{64}Cu detached from it after a 4 h incubation with mouse serum). ^{64}Cu-PCD-1-F3 (~0.7 GBq/mg) had a circulation half-life of ~ 15 min in mice (from dynamic PET scans) and possessed potent and persistent uptake in MDA-MB-231 (3.6 ± 0.8 %ID/g at 24 h post-injection) than that from ^{64}Cu-PCD-1 (0.7 ± 0.2 %ID/g at 24 h p.i.), and this uptake could be successfully blocked (to 0.9 ± 0.3 %ID/g at 24 h p.i.) by co-injection of excessive amount of F3 peptide (10 mg/kg). Histological analysis of MDA-MB-231 tumors indicated that PCD-1-F3 indeed bound to nucleolin (overexpressed in tumor cell membrane) from tumors. At the treatment dose, natCu-PCD-1-F3 could significantly delay the growth of tumor burden. Conclusion: Our study confirmed the uniqueness of PCD-1 as an anti-cancer agent and a natural "chelator" for copper (radioactive or non-radioactive).

OP-642

Efficient preparation of 2-[¹⁸F]fluorophenylalanine (2-[¹⁸F]FPhe) by Cu-mediated radiofluorination

D. Modemann[1], B. Zlatopolskiy[2], J. Ermert[1], B. Neumaier[1,2]; [1]Forschungszentrum Jülich GmbH, Institute of Neuroscience and Medicine, INM-5, Jülich, GERMANY, [2]Institute of Radiochemistry and Experimental Molecular Imaging, University Clinic Cologne, Köln, GERMANY.

Objectives: 2-[¹⁸F]FPhe has been successfully applied as a PET tracer for imaging of cerebral infarction and tumors. However, the absence of convenient preparation methods of this probe precludes its broad clinical application. The aim of this work was to develop an efficient procedure suitable for the fast production of clinical doses of 2-[¹⁸F]FPhe based on the recently developed Cu-mediated ^{18}F-fluorination of (aryl)(mesityl)iodinium salts. **Methods:** Substrate for radiolabeling, Boc_2-2-[(I⁺Mes)BF_4⁻]PheOtBu, was prepared in four steps starting from HCl×HPheOt-Bu. Cu-mediated ^{18}F-fluorination was accomplished under "minimalist" conditions using only precursor, ^{18}F⁻ and Cu-catalyst. Alternatively, traces of base for ^{18}F⁻-elution were applied ("low-base" protocol)[1] The labeling conditions were optimized with respect to temperature, solvent, amount of $(MeCN)_4$CuOTf and TEABC ("low-base" approach). Boc_2-2-[¹⁸F]FPheOtBu was purified by solid phase extraction and hydrolyzed with 12 M HCl affording after HPLC-purification the desired PET probe. **Results:** The precursor was synthesized in a yield of 31%. Under optimized conditions 2-[¹⁸F]FPhe was prepared in up to 43% radiochemical yield (RCY) and with a radiochemical purity of >99% within 100 min. Unexpectedly, radiolabeling under "minimalist" conditions led to the formation of up to 20% D-enantiomer. Fortunately, adjustment of ^{18}F⁻ processing allowed to suppress racemization (*ee* >98%). Similarly, the "low-base" approach using Et_3NHCO_3 (1 mg) in MeOH enabled the preparation of enantiomerically pure 2-[¹⁸F]FPhe in 48±8% (n = 3) RCY. **Conclusions:** Clinical doses of 2-[¹⁸F]FPhe were efficiently prepared by Cu-mediated ^{18}F-fluorination of the easily accessible iodonium salt precursor under "low base" conditions. The simplicity of the translation of the proposed procedure to automated synthesis modules [2] should open up the venue for the clinical application of 2-[¹⁸F]FPhe. **Research support:** This work was supported by the DFG grant ZL 65/1-1. **Literature:** [1] B. D. Zlatopolskiy, Chem. Eur. J., 2015, 21, 5972-5979. R. Richarz, Organic & biomolecular chemistry, 2014, 12, 8094-8099. [2] J. Zischler, Appl. Radiat. Isot., 2016, 115, 133-137.

OP-643

Influence of composition of cysteine-containing peptide based chelators on biodistribution of ⁹⁹ᵐTc-labelled anti-EGFR affibody molecules

M. Oroujeni[1], K. G. Andersson[2], J. Garousi[1], M. Altai[1], A. Vorobyeva[1], X. Steinhardt[2], B. Mitran[1], S. Ståhl[2], A. Orlova[1], J. Löfblom[2], V. Tolmachev[1]; [1]Uppsala University, Uppsala, SWEDEN, [2]KTH-Royal Institute of Technology, Stockholm, SWEDEN.

Aim: Epidermal growth factors receptor (EGFR) is overexpressed in a number of malignant tumours. In vivo molecular imaging of EGFR expression may provide prognostic, predictive and pharmacodynamic information and facilitate selection of treatment and a therapy response monitoring. Earlier, we have demonstrated feasibility of imaging of EGFR expression in xenografts using ¹¹¹In-labelled anti-EGFR Z2377 affibody molecule. Feasibility of the ⁹⁹ᵐTc-labelling of anti-HER2 affibody molecules using anti-HER2 cysteine-containing peptide based chelators was shown. These chelators can be incorpo-

rated into sequence during recombinant production. In addition, the use of different amino acids permits modification of biodistribution. The aim of this study was to evaluate the use of chelators glycine-glycine-glutamate-cysteine (GGEC), glycine-glutamate-glutamate-cysteine (GEEC), and glutamate-glutamate-glutamate-cysteine (EEEC) for labelling of anti-EGFR affibody molecules with [99m]Tc. **Materials and Methods:** Variants of Z2377 containing C-terminal sequences GGEC, GEEC and EEEC were produced and characterised. The affibody molecules were labelled with ^{99m}Tc using transchelation from gluconate. In vitro characterisation was performed using EGFR-expressing A431, MDA468 and PC3 cell lines. Biodistribution of conjugates was measured in BALB/C nu/nu mice bearing A431 xenografts. To check in vivo specificity, EGFR in a part of xenografts was pre-saturated by injection of anti-EGFR antibody cetuximab. **Results:** Initial labelling experiments revealed a presence of a second binding pocket with weak binding of [99m]Tc. Incorporation of pre-purification cysteine challenge enabled obtaining of stable conjugates. The labelling yield was 83.5 ± 4.2 , 84.6 ± 4.9 and 54.9 ± 7.5 % for ^{99m}Tc-Z2377-GGEC, ^{99m}Tc-Z2377-GEEC, and ^{99m}Tc-Z2377-EEEC, respectively. After purification using size-exclusion NAP-5 cartridges, the radiochemical purity of all variants was higher than 95%. All ^{99m}Tc-labelled Z2377 variants retained specific binding to EGFR-expressing cells and high affinity. All conjugates demonstrated EGFR-specific targeting of A431xenografts. Composition of chelators had strong influence on biodistribution. Increase of number of glutamates in the chelators was associated with rapider clearance from blood and lower uptake in salivary gland, lung, liver, stomach, colon and muscle. At the same time, ^{99m}Tc-Z2377-EEEC had the highest retention in kidneys. ^{99m}Tc-Z2377-EEEC provided the highest tumour-to-blood ratio of 27±5 at 24 h after injection, which is higher than the value of ^{111}In-DOTA-Z2377 at this time point (14±4). **Conclusion**: Cysteine-containing peptide-based chelators can be used for labelling of anti-EGFR affibody molecules with preserved specificity. Amino-acid composition of such chelators has strong influence on biodistribution and can be used modification of pharmacokinetics of affibody molecules.

H4neunpa-trastuzumab: Evaluation of a Novel Bifunctional Chelator for 111In Radiopharmaceuticals and Immuno-SPECT Imaging

S. Spreckelmeyer[1,2], C. F. Ramogida[3], J. Rousseau[4], K. Arane[1], I. Bratanovic[3], N. Colpo[4], U. Jermilova[3], G. M. Dias[4], I. Dude[4], M. Jaraquemada-Pelaez[1], F. Benard[4], P. Schaffer[3], C. Orvig[1]; [1]Medicinal Inorganic Chemistry Group, Department of Chemistry, University of British Columbia, Vancouver, BC, CANADA, [2]Dept. Pharmacokinetics, Toxicology and Targeting, Research Institute of Pharmacy, University of Groningen, Groningen, NETHERLANDS, [3]Life Sciences, TRIUMF, Vancouver, BC, CANADA, [4]BC Cancer Agency, Vancouver, BC, CANADA.

Introduction: [111]In ($t_{1/2}$ = 2.8 days) is an attractive radiometal for both therapeutic and imaging applications. Our group has developed a series of "pa" (picolinic acid) chelators with specific binding properties for a great number of radiometals.[1] Herein, we report the synthesis, potentiometric determination of stability constants and several *in vitro* as well as *in vivo* radiolabeling experiments with respect to the evaluation of H[4]neunpa-trastuzumab as a potent radiopharmaceutical in comparison to CHX-A"-DTPA-trastuzumab. **Subjects and Methods:** H[4]neunpa-*p*-Bn-NCS was synthesized starting from the backbone diethylenetriamine and the functionalization was placed on the middle nitrogen atom to keep its symmetry. Coupling of HER2/*neu* targeting antibody trastuzumab was performed via the reaction between the mAb-amine(s) with the isothiocyanate functional group of H[4]neunpa-*p*-Bn-NCS. RCYs of ^{111}In-radiolabeling and serum stability experiments were determined by radio-HPLC, size-exclusion PD-10 columns or iTLC-SG. Immuno-SPECT imaging of [^{111}In]neunpa-trastuzumab with HER2/*neu* positive tumour bearing female mice was performed compared to gold-standard [^{111}In]CHX-A"-DTPA-trastuzumab. Additionally, potentiometric stability constants were determined. **Results:** Radiolabeling with ^{111}In of the precursor H[4]neunpa-*p*-Bn-NO[2] as well as the mAb derivative, H[4]neunpa-trastuzumab, was carried out. Both chelators show labeling efficiencies >90 % within 15 minutes at room temperature and 97% or 95% human serum stability over 5 days, respectively. Immuno-SPECT imaging showed promising tumour uptake of 27.5 ± 6.2% ID/g (n = 4), with respectable blood clearance and low dosage in other organs after 5 days post-injection. **Conclusion:** The acyclic chelator H[4]neunpa-trastuzumab shows outstanding *in vitro* ^{111}In-radiolabeling kinetics with good tumour uptake *in vivo*.

OP-645

2-[^{18}F]Fluoro-5-iodopyridine ([^{18}F]FIPy): a novel thiol reactive prosthetic group for the fast site specific labeling at ambient temperature

A. Omrane[1,2], B. Zlatopolskiy[2,3], B. Neumaier[1,2,3]; [1]Forschungszentrum Juelich GmbH: Institute of Neuroscience and Medicine, INM-5, Juelich, GERMANY, [2]Institute of Radiochemistry and Experimental Molecular Imaging, University Clinic, Cologne, GERMANY, [3]Max Planck Institute for Metabolism Research, Cologne, GERMANY.

Aim: Novel ^{18}F-labeled prosthetic groups for the site specific labeling of sensitive biopolymers under mild conditions are highly sought after. The aim of this work was the study of the applicability of Pd-catalyzed *S*-arylation for indirect radiofluorination of biomolecules. To this end the simple and reliable procedure for the preparation of the suitable radiofluorinated iodo(hetero)arene should be first developed. **Methods:** Hitherto unknown [^{18}F]FIPy was chosen as a potential radiolabeled building block for Pd-catalyzed C(sp[2])-S coupling. The appropriate radiolabeling precursor, 1-(5-iodopyridin-2-yl)-1,4-diazabicyclo[2.2.2]octan-1-ium triflate (**1**), was prepared by the direct reaction of 2-bromo-5-iodopyridine with DABCO followed by anion metathesis using TMSOTf. [^{18}F]Fluoride was eluted from a QMA cartridge with **1** in MeOH. MeOH was evaporated at 45 °C (250 mbar) within 4 min, the appropriate solvent was added and the resulting solution was heated affording [^{18}F]FIPy. The latter was purified by SPE and thereafter conjugated with Boc-

Cys-OMe and glutathione (H-Glu-Cys-GlyOH) in aqueous THF using Pd-G3-Xantphos as catalyst. The both reaction steps were optimized with respect to different reaction parameters. The developed procedure was translated to an automated synthesis module. **Results:** [18F]⁻ recovery from an anion exchange resin using **1** (3 mg) amounted > 98%. Heating of the resulting [18F] fluoride onium salt in DMSO at 100 °C for 15 min afforded [18F] FIPy in radiochemical conversions (RCCs) of 98±2%. [18F]FIPy was isolated in 67±4% radiochemical yield (RCY) and excellent radiochemical purity (RCP) of > 98%. The subsequent **S**-arylation step afforded under optimized reaction conditions (0.5 μmol thiol, 0.1 μmol G3-Xantphos, 3 μmol NEt₃ 240 μL 50% THF, rt, 5 min) the corresponding conjugates in RCCs > 97%. The automated radiosynthesis furnished **S**-2-[18F]fluoropyrid-5-yl substituted glutathione in RCY of 35% (EOB) on two steps within 60 min. **Conclusion:** Pd-catalyzed **S**-arylation with [18F]FIPy is a powerful tool for the fast thiol specific radiolabeling of biomolecules under ambient conditions. [18F]FIPy is a valuable radiolabeled prosthetic group easily accessible using the "minimalist" approach.

Regional hepatic glucose metabolism correlates with regional distribution of hepatic fat

A. Dunford¹, G. Keramida², M. Aplin¹, A. M. Peters³; ¹Royal Sussex County Hopsial ,Brighton, UK, Brighton, UNITED KINGDOM, ²Royal Brompton and Harefield Hospitals NHS,FT, London, UNITED KINGDOM, ³Royal Sussex County Hopsital ,Brighton, UK & Clinical Imaging Sciences Centre , Brighton Sussex Medical School, Brighton, UK, Brighton, UNITED KINGDOM.

Aim: Hepatic steatosis is associated with insulin resistance and hyperinsulinaemia. Insulin stimulates hepatic glucokinase, even in insulin-resistance, so hepatic glucose uptake (MRglu), which is the product of FDG clearance and blood glucose, is increased in hepatic steatosis. The intrahepatic distribution of fat is heterogeneous. The study aim was to test the hypothesis that, in addition to systemic stimuli, hepatic MRglu is also related to hepatic fat on a regional basis within the individual liver. **Methods:** Twenty patients undergoing routine PET/CT using 18F-fluorodeoxyglucose (FDG) also had dynamic PET for 30 min following FDG injection. They then had routine whole body PET/CT at 60 min post-injection. Hepatic FDG clearance was measured using Patlak-Rutland graphical analysis. The gradient of the Patlak-Rutland plot (Ki) was normalised to the intercept (V(0)), which represents hepatic FDG distribution volume. The 60 min CT was co-registered on to each of the 30 dynamic PET frames. Within transaxial sections, the liver was divided into multiple small regions of interest (ROI) of 5x5 pixels each in sections of 5 mm (range 118-586 ROI per liver). CT density (CTD) and Ki/V(0) were measured in each ROI. As FDG does not enter hepatic fat, normalisation of Ki to V(0) means that FDG clearance was referenced to lean liver, otherwise a correlation between Ki/V(0) and CTD would be inevitable. **Results:** The average mean grid value for Ki/V(0) for all 20 patients was 0.39 ± SD 0.23 ml/min/100 ml. There was a trend towards a negative correlation between mean grid Ki/V(0) and mean grid CTD (r = -0.39; p = 0.09). Throughout the 25-pixel ROIs in the individual liver, CTD and Ki/V(0) correlated negatively and significantly (p <0.05) in 16 of 20 patients, but significantly positively in none. A one-sample **t**-test on the entire set of correlation coefficients (μ = −0.244, σ = 0.12 and n = 20), with a null hypothesis of a correlation coefficient of zero, yielded a **p**-value of <0.0001. In some patients, parametric imaging showed a regional concordance between Ki/V(0) and hepatic fat, identified as reduced CTD. **Conclusions:** In addition to a systemically driven increase, hepatic MRglu is also regionally linked to the distribution of hepatic fat. This increased regional metabolism could be the stimulus for local fat deposition or conversely the result of increased FDG accumulation in metabolically active inflammatory cells migrating in response to regional fat deposition.

OP-651
Assessment of Effect of Fatty Infiltration on Hepatic FDG Uptake

F. Özülker¹, T. Özülker²; ¹University of Health Sciences, Okmeydanı Hospital, Department of Nuclear Medicine, Uskumruköy/Sarıyer/ İstanbul, TURKEY, ²University of Health Sciences, Okmeydanı Hospital, Department of Nuclear Medicine, Uskumruköy/Sarıyer/ İstanbul, TURKEY.

Purpose: Physiological liver FDG uptake in FDG PET/CT studies, has been used as a reference in the assessment of the FDG

uptake in pathological processes including malignancies. There is an ongoing debate on the effect of liver attenuation and the liver's FDG uptake. We aimed to assess the any possible effect of fatty infiltration on the standardized uptake value (SUV) of the liver. **Subjects and Methods:** A total of 88 patients were included in this study. Subjects were divided into 2 groups by calculating the Hounsfield unit (HU) of the liver from the unenhanced CT part of the PET/CT study and comparing it with that of the spleen. The fatty liver group included 42 patients (26 female, 16 male) with a mean age of 59,6 ±11,6, while the control group were consisted of 46 patients (22 female, 24 male) with a mean age of 60,2± 11. The patients whose mean liver attenuation value in terms of HU, equal and greater than that of spleen were enrolled in the control group, while the patients with a mean attenuation value of liver lower than spleen were assigned to fatty liver group. A subset of patients from the fatty liver group with a HU difference between liver and spleen of 10 or more (HUS-HUL >10) were evaluated separately. The age, DM and chemotherapy history, weight of the subjects, serum ALT and AST levels, simultaneous blood glucose levels during PET scan and the elapsed time between the FDG injection and beginning of PET scan were recorded. **Results:** The average SUVmean and SUVmax values were calculated as 2,7+/-0,7 and 3,6+/-0,9, in the fatty liver group, 2,8± 0,7 and 3,8 ± 1 in the HUS-HUL >10 group and 3,3+/-0,6 and 4,4+/-0,9, in the control group respectively. The average SUVmean and SUVmax values in the fatty liver group and the subset of of HUS-HUL >10 group were significantly different from the values in the control group (p < 0.05). The patients in the fatty liver group showed higher ALT (p=0,025), weight (p=0,001), glucose levels (p=0,001) and ratio of DM (p=0,002), than the patients in the control group. **Conclusion:** Hepatic steatosis causes a statistically significant decrease in SUVmean and SUVmax values in liver. Therefore we must be cautious while using the liver as an internal reference organ.

OP-652

The correlation between pathological profile and metabolic parameters of ^{18}F-FDG PET/CT in patients with gastroesophageal junction cancer

J. Song; Beijing Cancer Hospital, Beijing, CHINA.

Objective: Histopathologic features and molecular pathological indicators could affect the FDG uptake of primary gastroesophageal junction carcinoma (GEJC) and detection rate on ^{18}F-FDG PET/CT. The aim of this study was to evaluate the FDG uptake of local advanced GEJC by correlating it with the histopathologic features and molecular pathological indicators of the tumors. **Methods:** Data pertaining to patients with a histopathological diagnosis of GEJC between January 2010 and December 2015 were retrospectively analyzed. A total of 66 patients (59 years, 63.97±7.5 years) with locally advanced gastroesophageal junction adenocarcinoma who were referred for preoperative ^{18}F-FDG PET/CT scans were enrolled in this study. The maximum standardized uptake values (SUV$_{max}$), metabolic tumor volume (MTV), and total lesion glycolysis (TLG) of the primary tumor

were measured and calculated with the region of interest (ROI) technique. These relationship between metabolic parameters and Lauren's classification, histologic differentiation and the status of Ki-67, human epidermal growth factor receptor 2 (HER2), c-Met and epidermal growth factor receptor (EGFR) were investigated in all of GEJC patients. **Results:** Significant differences were observed between intestinal and no-intestinal (mixed and diffuse) adenocarcinoma in SUV$_{max}$ (8.23±2.83 vs 6.29±2.41, P = 0.008), SUV$_{mean}$ (4.85±1.47 vs 3.93±1.22,P=0.017), MTV (24.96 cm^3 vs 11.17cm^3; P = 0.004) and TLG (97.38 cm^3 vs 47.12 cm3, P = 0.005). SUV$_{max}$, MTV, and TLG of the moderately differentiated adenocarcinomas were significantly higher than those of the poorly differentiated ones. SUV$_{max}$ was significantly higher in the high Ki-67 index or c-Met-negative group (P=0.045, P=0.036). No significant correlation was found between metabolism parameters and the expression of Her2 and EGFR in GEJC. **Conclusion**: ^{18}F-FDG metabolism parameters in GEJC is associated with Lauren's classification, histologic differentiation, Ki-67 and c-Met expression. ^{18}F-FDG PET/CT may be useful for predicting the pathological characteristics and molecular pathological indicators and for determining the therapeutic strategy.**Corresponding author:**Xuejuan Wang

OP-653

Early variation of FDG-PET parameters as predictors of response after treatment in locally advanced pancreatic carcinoma patients

E. Incerti[1], P. Mapelli[1], E. G. Vanoli[1], S. Broggi[2], C. Gumina[3], N. Slim[3], P. Passoni[3], C. Fiorino[2], G. M. Cattaneo[2], L. Gianolli[1], N. Di Muzio[3], M. Picchio[1]; [1]Unit of Nuclear Medicine, IRCCS San Raffaele Scientific Institute, Milan, ITALY, [2]Unit of Medical Physics, IRCCS San Raffaele Scientific Institute, Milan, ITALY, [3]Unit of Radiotherapy, IRCCS San Raffaele Scientific Institute, Milan, ITALY.

Purpose: To assess the predictive role of FDG-PET parameters in locally advanced pancreatic cancer (LAPC) patients treated with induction and concomitant chemo-radiotherapy (CRT) on overall survival (OS), local relapse free survival (LRFS), distant relapse free survival (DRFS) and progression free survival (PFS). **Subjects & Methods:** Fifty-two LAPC patients (median age: 60 years; range: 35-85 years) were enrolled at San Raffaele Scientific Institute. Patients received 44.25 Gy in 15 fractions to the tumour: 24/52 patients received a simultaneous integrated boost (48-58 Gy) to a sub-volume infiltrating the great abdominal vessels. FDG-PET/CT was performed before CRT (PET-pre) and after CRT (PET-post) at a median time of 3 months after the end of CRT (range: 1-6 months). The predictive value of FDG-PET parameters between PET-pre and PET-post was investigated, including the percentage variation of mean/maximum standard uptake value (ΔSUV$_{mean/max}$), metabolic tumour volume (ΔMTV) and total lesion glycolysis (ΔTLG), estimated considering different uptake thresholds (40-50-60%). The percentage difference between gastrointestinal cancer-associated antigen (ΔGICA) levels measured at the same time of PET scans was also considered. For each parameters, the median percentage variation was used to categorize patients: log rank test and Cox regression were performed to assess the prog-

nostic value of the considered parameters on OS, LRFS, DRFS and PFS. **Results:** The median follow-up was 13 months (range: 4-129 months). Median OS, LRFS, DRFS and PFS after the start of the CRT treatment were 13, 12, 5, 4 months, respectively. ΔTLG50 showed borderline significance in predicting OS (*p*= 0.053; RR= 0.54) and was the most significant FDG-PET parameter correlated to LRFS (*p*= 0.001; RR= 0.22). The median value of LRFS was 33 months compared to 7 (*p* =0.0024) and 4 months (*p*= 0.0003), respectively for ΔMTV40 and ΔTLG50 lower/higher the best cut-off value. No correlation was found between the percentage variation of FDG-PET parameters and DRFS while the ΔGICA was a borderline significant predictor (*p*= 0.076; RR= 0.50). ΔTLG50 was significant in predicting PFS: a median PFS equal to 6 vs 3 months (*p*= 0.0009) was found depending on ΔTLG50 value. **Conclusion:** Early variation of FDG-PET parameters predicts LRFS in LAPC patients; in particular, a larger reduction of TLG50 was strongly associated to a better LRFS. The change of GICA values was found to be of borderline significance for DRFS. The combination of early variation of PET predictors and GICA is promising in identifying patients at higher risk of local and/or distant relapse.

OP-654

Robotic arm assisted real time ¹⁸F-FDG PET/CT guided percutaneous metabolic sampling of abdominal lesions-Initial Experience

R. Kumar, B. R. Mittal, H. Singh, T. K. Jain, A. Sood, A. Bhattacharya; PGIMER, Chandigarh, INDIA.

Objective: In this prospective study, we aimed to establish the feasibility of automated robotic arm (ARA) assisted ¹⁸F-FDG PET/CT-guided sampling of abdominal lesions and its diagnostic utility in patients with prior inconclusive conventional image-guided biopsies. **Materials and Methods:** Forty-nine patients (30 males, 19 females) with median age 51.84 years (22-78 years) with abdominal masses but prior inconclusive conventional biopsy results were subjected to ARA assisted PET/CT-guided biopsy. All patients underwent diagnostic ¹⁸F-FDG PET/CT scan prior to PET/CT-guided percutaneous biopsy. The site of biopsy was planned from the most accessible FDG avid lesion in each case. The intervention was planned 2 hours after the initial diagnostic study by obtaining a limited field of view PET/CT. The needle trajectory was planned with the help of automated robotic arm (ARA) needle navigation technique. After confirming the position of the needle tip to the target site, real time sampling was done. To check the accuracy of the interventional procedure, histopathology reports were reviewed. For confirmation of negative results, clinical or imaging follow-up was done. **Results:** Among the total 49 patients, PET-guided biopsy was performed from lesions in retroperitoneum (n=21), mesentery and anterior abdomen (n=8), iliac lymph nodes/ pelvis (n=6), liver (n= 5); kidney (n=3); pancreas (n=2), and one each from spleen, adrenal, stomach and ileocaecal junction. Diagnostic results were yielded in all biopsy procedures. Malignancy was detected in 36 patients while 7 patients with minimal residual FDG uptake on follow-up PET/CT did not show any residual tumor from the biopsy tissue. Remaining six patients had benign etiology

(tuberculosis-1 sarcoidois-1, follicular hyperplasia-1, hepatitis-1, pyelonephritis-1 and inflammation -1). Repeat biopsies were done in two patients, one with no residual tumor and other with inflammation on the previous biopsy, yielded the same results. So far, the clinical and imaging follow-up in disease negative patients was uneventful. No immediate complications or delayed life threatening event related to the procedure were noted in our patients. The diagnostic yield of real-time PET/CT-guided metabolic biopsy from abdominal lesions was 100%. **Conclusions:** ARA assisted ¹⁸F-FDG PET/CT-guided percutaneous real time metabolic sampling of abdominal lesions is technically feasible with high diagnostic yield in patients with prior inconclusive biopsies.

OP-655

The Role of ¹⁸F-Sodium Fluoride (NaF) PET-CT in the evaluation of metastatic bone disease in morbidly obese patients

S. Usmani, F. Marafi, A. Esmail, F. al kandari; Kuwait Cancer Control Center, kuwait, KUWAIT.

Purpose: Diagnostic imaging remains challenging in obese patients. The quality of conventional bone scintigraphy is generally poor in the morbidly obese due to a combination of factors including high background soft tissue activity. In comparison, ¹⁸F-sodium fluoride (NaF) PET-CT has a better target to background ratio attributed to rapid single-pass extraction and fast clearance from the soft tissues. The aim of the present study is to evaluate the emerging role of ¹⁸F-NaF PET-CT in the evaluation of bone metastases in morbidly obese patients. **Subjects and Methods:** Two hundred and twelve morbidly obese patients (BMI 45±5.1 Kg/m² and mean age, 57years; range 32-81years) with BMI >40kg/m² referred for ¹⁸F-NaF PET-CT for osseous staging of malignancy were retrospectively analyzed. All patients underwent PET-CT scan by injecting 0.06 mCi/kg of ¹⁸F-NaF. **Results:** ¹⁸F-NaF PET-CT was definitely benign in 145, possibly benign in 3; equivocal in 4; possibly malignant in 13 and definitely malignant in 47 patients. The sensitivity, specificity, PPV, NPV and accuracy of 18F-NaF PET-CT were 93.1%, 96.1%, 90%, 97.3% and 95.2% respectively (p<0.001). **Conclusions:** The results of the present study indicate that ¹⁸F-NaF PET-CT retains its high diagnostic accuracy in morbidly obese patients and may even be a preferred modality for this patient group.

OP-656

Tc-99m-DPD bone scan quantification: Metastasis of prostate cancer vs. osteoarthritis

F. Tabotta, M. Jreige, N. Schaefer, J. O. Prior, M. Nicod Lalonde; CHUV, Lausanne, SWITZERLAND.

Purpose: Bone scintigraphy with Tc-99m labeled DPD can identify metastatic prostate bone lesions with a high sensitivity but a low specificity, as benign conditions and especially osteoarthritis also trigger an osteoblastic reaction. The aim of this study is to investigated the emerging role of Tc-99m DPD

uptake quantification in order to compare the value of SUV in metastases and degenerative lesions. **Materials and Methods:** retrospectively assessed 12 patients (mean age 70±9 years) with known bone metastases of prostate cancer and 17 patients (mean age 70±12 years) with benign degenerative conditions without any known neoplastic condition. Quantitative xSPECT/CT (Siemens SYMBIA INTEVO) was acquired and SUV quantified on post-processed images with measurements of SUVmax and SUVmean (g/ml) in all bone metastasis and in the degenerative lumbar spine changes for the osteoarthritic group. We also used receiver operating characteristics (ROC) curves to determine the metastatic vs. benign origin of lesions. **Results:** A total number of 128 metastatic lesions (100 blastic, 3 lytic and 25 mixed) were analyzed showing a mean SUVmax and SUVmean (g/ml) of 46±29 (18-176) and 29±18 (11-96), respectively. In 17 osteo-arthritic lesions (mainly blastic) mean SUVmax and SUVmean were of 16.6±2.4 (12.4-20) and 11.8±1.7 (8.9-14.7) respectively. Comparison of both SUVmax and SUVmean between the metastatic and osteoarthritic groups showed a statistically significant difference with p<0.0001 for both, with SUVmax offering significantly better accuracy (AUC 0.989 vs. 0.959, p=0.009). Using a SUVmax threshold of 20 g/mL to define bone metastatic lesion, we found a sensitivity, specificity, positive and negative predictive vales of 94%, 94%, 99% and 67%, respectively. **Conclusions:** This study showed significant differences in Tc-99m-DPD uptake on bone scan between prostate metastatic lesions and osteoarthritic changes based on quantitative data analysis, with significantly higher SUVmax and SUVmean in metastases, with better accuracy for SUVmax. Thus, quantitative analysis of bone scan quantitative data can be helpful for diagnosing malignant lesions by increasing its specificity.

OP-657

Convolutional neural networks for segmentation of 49 selected bones in CT images show high reproducibility

M. Sadik[1], R. Kaboteh[1], O. Enqvist[2], J. Ulén[3], E. Trägårdh[4], M. H. Poulsen[5], J. A. Simonsen[6], P. F. Høilund-Carlsen[6], L. Edenbrandt[1]; [1]Department of Clinical Physiology, Göteborg, SWEDEN, [2]Department of Signals and Systems, Göteborg, SWEDEN, [3]Eigenvision AB, Malmö, SWEDEN, [4]Department of Translational Medicine, Malmö, SWEDEN, [5]Department of Urology, Odense, DENMARK, [6]Department of Nuclear Medicine, Odense, DENMARK.

Aim: An automated method to calculate Bone Scan Index (BSI) from bone scans has recently been established as a first imaging biomarker in patients with metastatic prostate cancer. BSI has shown to be an independent predictor of survival. PET/CT is more accurate than bone scans in detecting bone metastases. We therefore decided to develop an automated PET/CT based imaging biomarker for assessment of tumor burden in bone. The aim of this project was to develop a method for automated segmentation and volume calculation of bones in CT images, which is the first step in the process of developing a PET/CT based imaging biomarker. **Materials and Methods:** Convolu-

tional neural networks (CNN) were trained to segment 49 selected bones (12 thoracic vertebrae, 5 lumbar vertebrae, sacrum, 2 hip bones, 24 ribs, 2 scapulae, 2 clavicles and the sternum) using manual segmentations in CT images from 23 patients performed by experienced image readers. Anatomical landmarks were detected using a CNN and pruned using a shape model. These landmarks and the CT image were fed to a second CNN, segmenting the 49 selected bones. After the training process, the CNN segmented the bones in CT images in a separate validation group consisting of 46 patients with prostate cancer. All patients had undergone both 18F-Choline and 18F-NaF PET/CT within a time frame of 3 weeks as part of a previous research project. The two CT scans from each patient were segmented by the CNN and the two volumes of each bone were calculated. **Results:** The total volume of the 49 bones was on average 3,086 mL in the 46 patients. The individual bones ranged in volume from 8 mL (left 12th rib) to 440 mL (left hip bone). The reproducibility measured as ratio volume difference/mean volume was on average less than 2% for all bones except for the ribs. The mean volumes, differences and reproducibility for the bones of five anatomical regions were as follow: thoracic vertebrae 39mL, 0.6mL, 1.5%; lumbar vertebra 71mL, 0.8 mL, 1.2%; sacrum, hip bones 386mL, 0.9mL, 0.3%; ribs 26mL, 2.0mL, 8.5%; scapulae, clavicles, sternum 97mL, -0.1mL, -0.4%. **Conclusion:** Our CNN based method for automated segmentation of bones in CT images showed high reproducibility. A reproducible way to segment the skeleton and to measure the bone volume will be important in the development of a PET index relating volumes of abnormal PET tracer uptake to the bone volume.

OP-658

Prognostic Value of Quantitative Coronary Artery Calcium and Myocardial Blood Flow Assessed by Hybrid Rubidium-82 PET/CT Imaging in Patients With Suspected Coronary Artery Disease

E. Zampella[1], R. Assante[1], T. Mannarino[1], G. De Simini[1], A. Genova[1], M. Panico[2], V. Gaudieri[2], C. Nappi[1], C. Mainolfi[1], W. Acampa[1], M. Petretta[3], P. Arumugam[4], A. Cuocolo[1]; [1]Department of Advanced Biomedical Sciences, University Federico II, Naples, ITALY, [2]Institute of Biostructure and Bioimaging, National Council of Research, Naples, ITALY, [3]Department of Translational Medical Sciences, University Federico II, Naples, ITALY, [4]Department of Nuclear Medicine, Central Manchester University Hospitals, Manchester, UNITED KINGDOM.

Aim: In this study we sought to evaluate the long-term prognostic value of coronary artery calcium (CAC) score and myocardial blood flow (MBF) by hybrid 82rubidium (82Rb) positron emission tomography (PET)/computed tomography (CT) imaging in a cohort of patients with low-intermediate risk of coronary ar-

tery disease (CAD). **Materials and Methods:** A total of 410 consecutive patients (mean age 56±13 years) with suspected CAD were studied. CAC score was measured according to the Agatston method and patients were categorized into 3 groups (0, 1-400 and >400). Baseline and hyperemic MBF were automatically quantified. Coronary flow reserve (CFR) was calculated as the ratio of hyperemic to baseline MBF and it was considered reduced when <2. Patients were followed up for the presence of composite endpoint of cardiac death, nonfatal myocardial infarction, or unstable angina requiring coronary revascularization whichever occurred first. **Results**: The median follow-up was 47±15 months and follow-up data were not available in 26 patients (6%). Patients who experienced events showed higher CAC score (P<0.001) and lower hyperemic MBF (P<0.05) and CFR (P<0.001) values compared to patients without events, while there were no differences in baseline MBF between the two group of patients. Event rate significantly increased with increasing of CAC score categories (P for trend <0.001) and it was higher in patients with reduced CFR (P<0.001). At multivariable analysis, CAC score >400 (P=0.006) and CFR (P=0.004) were independent predictors of events. Event-free survival decreased with worsening of CAC score category (P<0.001) and in patients with reduced CFR (P<0.005). CAC score added prognostic information to a model including in hierarchical order clinical variables, increasing the global chi-square from 23.16 to 33.70 (P=0.002). The addition of CFR to a model including clinical data and CAC score further increased the global chi-square from 33.70 to 42.45 (P=0.001). **Conclusion**: In patients with low-intermediate risk of CAD both the extent of coronary calcification and the presence of coronary vascular dysfunction are associated with increased risk of adverse cardiac events, even after adjustment for cardiovascular risk factors. CAC score and CFR are independent predictors of events, however CFR provides incremental prognostic information over established CAD risk factors and CAC score. Combined evaluation of functional and structural abnormalities by hybrid 82Rb PET/CT imaging might allow risk stratification in patients with low-intermediate risk of CAD.

OP-659

Cardiac ⁸²Rb PET/CT: The added value in diabetic Heart Transplant Patients

M. L. De Rimini[1], G. Borrelli[1], A. Russo[2], S. Carrino[3], C. Maiello[4], P. Muto[1]; [1]Nuclear Medicine Unit - AO Ospedali dei Colli - Monaldi, Naples, ITALY, [2]Cardiovascular Unit; Vanvitelli University of Campania, Naples, ITALY, [3]Pharmacy Unit - AO Ospedali dei Colli - Monaldi, Naples, ITALY, [4]Cardiac Transplant Unit - AO Ospedali dei Colli - Monaldi, Naples, ITALY.

Introduction: The integration of cardiac PET in CAD disease management algorithms, with evaluation of myocardial blood flow (MBF) and flow reserve (MFR), will advance quality of care. This capability can be even more effective in heart transplant (HTx) recipients, considering that chronic immunologic responses afflicts first small vessels rather than the main ones and that it appears to be the cause of the occlusive long term cardiac allograft vasculopa-

thy (CAV). At state, it remains unclear whether mild, diffuse intimal thickening in the epicardial arteries of HTx recipients affects the functional status of the coronary tree. Aim: To evaluate the value of cardiac PET and MFR evaluation in HTx patients (pts). Methods: 82Rb (50mCi/phase) PET/CT (Siemens, 3D PET/CT Biograph, 16 slices) was obtained in Basal conditions and after Dypiridamole (0.56 mg/kg over 4 min) in 20 HTx pts. Dynamic protocol in list-mode was obtained and these dynamic studies were reconstructed from list mode. MBF, MFR and semiquantitative perfusion analysis were obtained with Quantitative PET (Q-PET) - Cedars-Sinai (by Germano). MFR value <2.0 was considered abnormal. Pts were selected in a larger population of HTx recipients, based on the following criteria: transplantation for at least 5 years, the absence of history of acute and chronic rejection and of stenosis at coronary angiography. 9 pts out of 20 were diabetic for at least 5 years, treated with oral therapy. Results: No evidence of transient ischemia at ECG during pharmacological test. Normal perfusion scans were found in all pts (average summed scores obtained: SSS=3; SDS=1; Extension perfusion defect Dypiridamole less than 2%). MBF and MFR were shown markedly reduced in diabetic pts than in non-diabetic ones, with a range of estimated values of MFR ranging from a maximum of 1.9 to a minimum of 1.1. Discussion: Chronic rejection still remain the major drawback of long-term positive outcome after HTx. In apparently healthy HTx subjects a reduced MFR in diabetic pts, compared with the normal MFR of non diabetic ones, can be a strong and independent predictor of outcome in HTx diabetic patients without evidence of main coronary artery disease and with negative dipyridamole stress test. Conclusion: In our limited, but strictly selected population of HTx pts, diabetes can be confirmed as a factor influencing MFR. Therefore, our results suggest that PET/CT with MFR evaluation could be particularly suitable for improving detection of CAV and for clinical management of HTx pts.

OP-660

Relationship between microvascular disease assessed using myocardial flow reserve with 82Rubidium positron emission tomography and the severity of diabetic nephropathy

*L. Potier[1], R. Chequer[2], C. Amouyal[3], K. Mohammedi[4], A. Hartemann[5], M. Marre[4], R. Roussel[4], D. Le Guludec[2], **F. Hyafil**[2]; [1]Department of Diabetology, Bichat Hospital, AP-HP, PARIS, FRANCE, [2]Department of Nuclear Medicine, Bichat Hospital, APHP, PARIS, FRANCE, [3]Department of Daibetology, Pitié-Salpetrière Hospital, APHP, PARIS, FRANCE, [4]Department of Diabetology, Bichat Hospital, APHP, PARIS, FRANCE, [5]Department of Diabetology, Pitié-Salpetrière Hospital, APHP, PARIS, FRANCE.*

Introduction: Diabetes mellitus is a cardiovascular risk factor for coronary atherosclerosis but is also involved in the alteration of myocardial microcirculation. 82Rubidium PET imaging (Rb-PET) offers to assess the microcirculation through the quantification of myocardial flow reserve (MFR). Our objective in this study was to evaluate in diabetic patients the link between alterations of microcirculation in the myocardium measured with Rb-PET and the severity of diabetic nephropathy.

Methods: Myocardial flow reserve (MFR) was measured with Rb-PET in 219 patients referred for screening of CAD. Patients with CAD were excluded from the analysis. Among the 184 remaining patients, global myocardial flow were calculated on PET acquisitions at rest and under pharmacological stress (dipyridamole) using the FlowQuant software. Global MFR was calculated as the ratio between stress and RPP-corrected rest myocardial flow. Plasmatic creatinin and urinary albumin concentrations were retrospectively collected in diabetic patients for the grading of the severity of diabetic nephropathy. **Results:** Mean age of patients was 59.1 ± 10.2 years ; 55.8 % of patients were women. Among the 184 patients, 127 were diabetic patients with an average exposure to diabetes of 13.0 ± 9.2 years and a mean HbA1c of 8.5 ± 1.7 %. Micro-albuminuria was present in 35 patients (27.6%) and macro-albuminuria in 12 patients (9.4 %). Rest LVEF was similar in patients with absent, micro- or macro-albuminuria (56.0±1.0 % ; 56.2±1.8 % ; 54.1±6.0 %, respectively ; p = 0.80). Mean global MFR was lower and the prevalence of patients with MFR < 2 was higher in diabetic than in non-diabetic patients (2.7 ± 1.1 vs. 3.4 ± 1.8, p < 0.01 ; 30.7 vs. 15.8 %, p < 0.05; respectively). Patients with absent, micro- or macro-albuminuria had mean global MFR measured at 2.9 ± 1.2, 2.3 ± 1.0 and 1.8 ± 0.7, and a prevalence of abnormal MFR of 18.8 %, 42.9 % et 75.0 %, respectively (p < 0.05 for differences between groups). In logistic regression analyses using different model of adjustment, microalbuminuria and macroalbuminuria were associated with a 3 and 13-fold increased risk of impaired MFR respectively. **Conclusions:** In this study, we found a strong association between the decrease of MFR quantified with Rb-PET and the severity of diabetic nephropathy. These results suggest that microvascular dysfunction in the heart and in kidneys might share common mechanisms in diabetic patients and represent an early marker of diabetic cardiomyopathy.

OP-661

Low-dose myocardial blood flow imaging using 82Rb-PET (RUBILOW 2.0)

C. M. Hoff, L. P. Tolbod, H. J. Harms, K. Bouchelouche, J. Frøkiær, J. Sørensen; Aarhus University Hospital, Aarhus, DENMARK.

Aim: Relative and absolute measures of myocardial blood flow (MBF) can be derived from a 82Rb PET/CT scan using list mode data to extract static, gated and dynamic PET series. High doses of 82Rb are used to maximize image quality in especially static images. High doses require large eluate volumes, may degrade scanner dead time performance at first pass and decreases generator lifetime. Lower doses will expand the availability of 82Rb PET/CT and lower doses to personnel and patients. The aim of the current study was to examine MBF with a low dose (LD) 82Rb protocol compared to the institution's standard (STD) protocol. **Methods:** Twenty-one patients referred to 82Rb PET were included in the study. Patients were examined during rest and stress with repeated LD (740 MBq) and STD dose (1110 MBq) Rb-PET during the same imaging session. Regional and global rest and stress MBF values, total perfusion deficit (TPD), ejec-

tion fraction (EF) and %-perfusion using the 17-segment model were calculated using commercially available software QPET (Cedars Sinai). **Results:** Five patients had to be excluded due to motion during STD (n=2) and LD (n=3). For the remaining patients, there was excellent correlation between STD and LD global MBF (STD=0.91xLD+ 0.08, R^2=0.95, p<0.001). Mean global MBF (±SD) at rest was 1.01 ±0.31 and 1.06±0.30 mL/g/min at STD and LD (p=0.17), and at stress 2.44±0.48 and 2.57±0.55 mL/g/min at STD and LD (p=0.07), respectively. On the segmental level, correlation between STD and LD MBF was high (STD=0.91xLD+0.09, R^2=0.92, p<0.001). Mean segmental MBF (±SD) at rest was 1.01 ±0.35 and 1.06±0.35 mL/g/min at STD and LD (p<0.001), respectively. At stress mean segmental MBF was 2.44±0.70 and 2.58 ±0.75 mL/g/min at STD and LD (p<0.001), respectively. There was an excellent correlation between STD and LD TPD (STD=0.90xLD-0.42, R^2=0.95, p<0.001). Mean TPD with STD was 7.5±6.9% and 8.8±7.5% with LD (p<0.001). Mean %-perfusion with STD was 77.3±9.0% and 76.4±9.1% with LD patients (p<0.001) with a good correlation between STD and LD %-perfusion (STD=0.92xLD+7.15, R^2=0.86, p<0.001). Mean EF with STD patients was 65±9% and 65±8% in LD patients (p=0.90) with a good correlation (STD=1.06xLD-3.70, R^2=0.90, p<0.001). **Conclusions:** The 82Rb dose can be lowered to 740 MBq without loss of diagnostic accuracy for both absolute and relative measurements. The low dose protocol should be implemented into clinical routine if a modern scanner is available. This will reduce radiation burden and increase patient throughput per generator.

OP-662

Value of Rubidium-82 Flow Measurements in Patients with CABG

B. J. H. G. van Gageldonk[1], A. T. L. Fiolet[1], I. E. M. Bank[2], A. Mosterd[1], H. J. Verberne[3], J. M. H. de Klerk[1], **A. M. Scholtens**[1]; *[1]Meander Medical Center, Amersfoort, NETHERLANDS, [2]University Medical Center, Utrecht, NETHERLANDS, [3]Academic Medical Center, Amsterdam, NETHERLANDS.*

Purpose: Rubidium-82 Positron Emission Tomography (Rb-82 PET) is a reliable technique to detect ischemia. Global myocardial stress flow in native coronary arteries (cut-off 2.0mL/g/min) is strongly related to clinical outcome. However, grafted coronary arteries may have different myocardial stress flow, due to differences in blood-to-vessel wall interactions and differences in diameter between arterial and venous grafts compared to native coronary arteries. Rb-82 PET myocardial stress flow values have not been validated for grafted coronaries specifically. Therefore we investigated Rb-82 PET global myocardial stress flow in patients who had undergone coronary artery bypass grafting (CABG). **Methods:** A retrospective analysis of all Rb-82 PET scans (n=2819) performed in our institution between February 2014 and May 2016 identified 295 scans in post-CABG patients. These patients were divided based on global myocardial stress flow ((<1.8mL/g/min; low (group 1, n=106), 1.8-2.0mL/g/min; borderline-low (group 2, n=39), >2.0mL/g/min; normal (group 3, n=150)). Left ventricular ejection frac-

tion (LVEF), myocardial blood flow and summed difference scores (SDS, indicating extent of ischemia) were compared across groups. During follow-up coronary revascularizations and acute coronary syndromes (ACS) were recorded. **Results:** Group 1 was minimally older than groups 2 and 3 (74.6±7.9 vs 71.6±10 vs 71.4±9.1 years, p<0.05) and had a higher percentage of males (86.8% vs 76.9% vs 64.7%, p<0.05). Grafts in group 1 were implanted longer ago than in the other groups (Graft age 13.1±7.9 vs 9.2±6.3 vs 9.7±7.2 years, p<0.05). Rb-82 PET measurements in the 'borderline-low' and 'low' group were comparable in terms of SDS (6.1±5.4 vs 4.2±4.4, p=0.100) and both resting LVEF (50.8±15.5% vs 55.3±13.6%, p=0.203) and stress LVEF (51.2±15.5% vs 57.3±14.0%, p=0.067). The 'normal' group had lower SDS (2.4±3.5) and higher LVEF in rest and at stress (62.1±11.5% and 64.5±11.6%, respectively). There was a significant difference across groups in patients free of ACS and/or revascularization during follow-up (71.4% vs 79.5% vs 88.1%, p=0.003; mean follow-up 644 days). **Conclusion:** Established Rb-82 PET myocardial blood flow velocity cut-off values provide useful (prognostic) information in CABG patients, comparable to the evaluation of native coronary arteries.

OP-663

Higher diagnostic performances of 82Rubidium-PET in comparison to SPECT myocardial perfusion scintigraphy for the detection of three-vessel coronary artery disease

F. Hyafil[1], R. Chequer[1], E. Sorbets[2], T. Alfaiate[3], H. Regaieg[1], F. Rouzet[1], N. Mikail[1], G. Ducrocq[4], R. Ben Azzouna[1], S. Leygnac[1], M. Milliner[1], C. Estellat[3], D. Le Guludec[1]; [1]Department of Nuclear Medicine, Bichat Hospital, AP-HP, Paris, FRANCE, [2]Department of Cardiology, Avicennes Hospitall, AP-HP, Bobigny, FRANCE, [3]Unite de Recherche Clinique Paris Nord, Bichat Hospital, AP-HP, Paris, FRANCE, [4]Department of Cardiology, Bichat Hospital, AP-HP, Paris, FRANCE.

Introduction: PET-MPS provides absolute quantification of stress and rest myocardial blood flow (MBF) and might improve the detection of balanced myocardial ischemia. The aim of this study was to compare the diagnostic performance of [99m]Technetium (Tc)-MIBI-SPECT-MPS and [82]Rubidium (Rb)-PET MPS for the detection of three-vessel coronary artery disease (3V CAD) in a population with a pre-test intermediate prevalence of CAD. **Methods:** All patients underwent gated MPS with ^{99m}Tc-MIBI using CZT cameras in association to the best stress test feasible and gated MPS with [82]Rb-PET during pharmacological stress with dipyridamole. Patients with at least one MPS considered as positive were referred for coronary angiography (CA). Patients were classified as positive for myocardial ischemia in case of significant stenosis (≥ 70%, or ≥ 50 % and FFR ≤ 0.8) on CA or, in absence of CA, occurrence of cardiovascular event during the following year. **Results:** Among 292 patients after exclusion of 16 patients with missing data, 17 patients had 3V-CAD or equivalent (LM stenosis > 50 % or significant stenosis of the proximal LAD), 17 patients 1- or 2-vessel CAD and 29 no significant coronary stenosis, or normal SPECT and PET-MPS with no cardiovascular event at follow-up (n = 229). The presence of LV end-di-

astolic dilatation ≥ 20 ml between stress and rest acquisitions had sensitivity and specificity for 3V-CAD of 31 % and 96 % with SPECT-MPS and 56 % and 86 % with PET-MPS (p = 0.01 for sensitivity; p < 0.001 for specificity); the presence of LVEF difference between stress and rest ≤ - 10 % for SPECT and ≤ 0 % for PET a sensitivity and specificity of 6 % and 91 % with SPECT-MPS, and 75 % and 83 % with PET-MPS, respectively (p < 0.05 for both). Sensitivity and specificity for the detection of 3V-CAD was 94 % and 60 % for stress MBF ≤ 1.8 ml/mn/g, and 81 % and 73 % for MFR ≤ 2.0. The association of diff. LVEF ≤ 0 % and decreased global stress MBF ≤ 1.8 ml/mn/g allowed for the identification of patients with 3V-CAD with a sensitivity of 75 %, a specificity of 92 % and an accuracy of 91 %. **Conclusions:** The detection of LV dysfunction and decreased global stress MBF with Rb-PET-MPS translates into higher diagnostic performances for the detection of patients with 3V-CAD in comparison to SPECT-MPS.

OP-664

Need for Correction of Myocardium Movement during Dynamic Rubidium-82 Stress PET for Accurate Myocardial Blood Flow Quantification

S. S. Koenders[1,2], J. D. van Dijk[1], P. L. Jager[1], C. H. Slump[2], J. Ottervanger[3], J. A. van Dalen[4]; [1]Department of Nuclear Medicine, Isala, Zwolle, NETHERLANDS, [2]MIRA: Institute for Biomedical Technology and Technical Medicine, University of Twente, Enschede, NETHERLANDS, [3]Department of Cardiology, Isala, Zwolle, NETHERLANDS, [4]Department of Medical Physics, Isala, Zwolle, NETHERLANDS.

Introduction: The use of myocardial blood flow (MBF) quantification with Rubidium-82 PET is rapidly growing. However, an upward creep of the myocardium may occur during dynamic stress acquisition due to an increase in lung volume and thereby repositioning of the diaphragm and myocardium in the post-pharmacological exercise period. This effect may result in a biased MBF measurement and hence hamper diagnostic accuracy. Our aim was to determine the impact of correcting for myocardium movement on MBF quantification during Rubidium-82 stress PET. **Subjects & Methods:** We retrospectively included 46 consecutive patients who underwent dynamic rest-pharmacological induced (Regadenoson) stress PET/CT (GE Discovery 690, GE Healthcare) with Rubidium-82. Dynamic data of both the rest and stress examinations were processed using Corridor4DM (v2015.02.64) software. Myocardium contours were automatically detected in both rest and stress. Upward creep during stress was assessed by identifying differences between the contour and the activity as observed in each of 26 reconstructed time-frames. If differences were observed, manual re-alignments were performed. Rest MBF and uncorrected and motion-corrected stress MBF were calculated for the three vascular territories: left anterior descending (LAD), left circumflex artery (LCX) and right coronary artery (RCA). MBF was calculated using the one-tissue compartment model of Lortie et al. based on region of interest methodology. Furthermore, coronary flow reserve (CFR, ratio of MBF at stress to rest) was calculated. **Results:** Myocardium movement was observed in 25 (54%) of the

46 patients. The mean differences in MBF between the non-corrected and motion-corrected stress data were -0.20 (range: -1.48 to 0.74), 0.05 (-1.00 to 1.35) and 1.60 (-0.68 to 7.67) ml/min/g for the LAD (p=0.15), LCX (p=0.3) and RCA (p<0.001), respectively. Motion correction resulted in a decreasing MBF in the RCA in 23 of the 25 patients. The lower MBF of the RCA also resulted in a significant decrease in mean CFR from 4.2 to 2.7 (p<0.001). **Conclusion:** Correction of the upward creep during Rubidium-82 stress PET significantly changes myocardial blood flow and coronary flow reserve quantification of the RCA, but neither of the LAD nor LCX. Myocardium movement detection and correction during dynamic Rubidium-82 stress PET likely improves accurate MBF quantification.

OP-665

Estimation and reliability of myocardial blood flow after motion correction with dynamic PET using a Bayesian framework

A. Saillant[1,2], K. Saint[3], M. Memmott[3], I. Armstrong[3], V. Shah[2], S. Zuehlsdorff[1], J. Declerck[4], M. Jenkinson[2], M. Chappell[2]; [1]Siemens Healthineers, Knoxville, TN, UNITED STATES OF AMERICA, [2]University of Oxford, Oxford, UNITED KINGDOM, [3]Central Manchester University Hospital, Manchester, UNITED KINGDOM, [4]Siemens Healthineers, Oxford, UNITED KINGDOM.

Introduction: The measurement of myocardial blood flow (MBF) in dynamic PET can be biased by many different processes. A major source of error is motion. The objective of this study was to measure the MBF along with an estimate of confidence in MBF from dynamic PET imaging. We employed a Bayesian inference framework that represents the kinetic parameters as a probability distribution, from which a confidence was estimated. We studied the percentage change of confidence in MBF after a manual motion correction in patients. **Subjects & Methods:** A cohort of 10 patients comprising Rubidium dynamic stress datasets was examined. The datasets were screened by an independent reviewer and considered to have a significant patient motion. The blood input function (BIF) and the time activity curves (TACs) were extracted using *syngo*.via (Siemens Healthineers). The motion was corrected using a rigid frame wise manual registration, starting from the last frame as reference. Only 3D translations were applied. The TACs were fitted with a one compartment model, with spillover factor (SF). We used a Variational Bayes (VB) algorithm for nonlinear model fitting. Each parameter (K1,k2,SF) was represented by a Normal (marginal) distribution $N(\mu,\sigma^2)$, where μ is taken as the best estimated parameter value, and σ as a measure of confidence in the estimate. Here K1 is used a surrogate for MBF. The percentage difference $\sigma/\mu(K1)$ is calculated before and after correction for the global value and individual coronary territories. It is calculated as follows: 100*(Original - MotionCorrected)/ Original. **Results:** On average for all patients, there was a 39% increase in the global value after motion correction implying that the correction impacted positively the confidence. For LAD, LCX and RCA territories increase of 25%, 50% and 69% was observed respectively. A large rise was seen in the RCA on average, imply-

ing that motion correction was most important here. **Conclusion:** In this preliminary study, we have demonstrated the use of a Bayesian inference scheme for MBF estimation that permits not only kinetic parameter estimation, but also the provision of confidence estimates. This could be used to examine the effectiveness of a rigid motion correction strategy, but could be extended in future to automatically assess the effectiveness of other pre-processing tasks.

Do.MoRe: Dosimetry in Diagnostic Nuclear Medicine

OP-666

Voxel based internal dosimetry of radiopharmaceuticals in diagnostic nuclear medicine

N. Petoussi-Henss[1], J. Ocampo Ramos[2], M. Zankl[1], W. Li[1], W. Rühm[1]; [1]Helmholtz Zentrum München, Neuherberg, GERMANY, [2]Universidad National de Colombia, Medellín Branch, COLOMBIA.

Aim: The aim of this presentation is to discuss the new framework of the International Commission of Radiological Protection, ICRP, for internal dose assessment for radiopharmaceuticals and highlight the differences from the previous framework. A further aspect is to discuss the accuracy of the calculations when applied to a real patient rather than the standard individual. Effective and organ doses per administered activity for reference as well as non-reference adults and for exposures due to some frequent diagnostic nuclear medical examinations will be presented. Furthermore, the mass scaling assumption used when the organ masses of the patient are known is investigated. **Background**: Radiation dose estimates require the use of biokinetic models, radionuclide decay scheme data, and values of Specific Absorbed Fractions (SAF). Recently the ICRP has released SAF for photons, electrons, alphas and fission-spectrum neutrons derived from Monte Carlo radiation transport simulations in the ICRP reference adult male and female voxel phantoms as well as in the human alimentary and respiratory tract models (ICRP Publication 133, 2017). **Methods:** A new user-friendly computer program with graphical user interface has been developed aiming at estimating the organ and effective doses to an individual due to internal exposures in nuclear medicine once the kinetic model is defined. In contrast to other programs which utilize a single adult male and a single adult female stylized phantom of reference size, the new software is employing, besides the new ICRP SAFs, a library of pre-calculated SAFs of photons and electrons, based on several anthropomorphic voxel phantoms of non-reference size. Furthermore, the software is using the most recent nuclear decay data and has been extensively beta-tested against other methods. **Results:** 1) Organ and effective dose coefficients for the reference person will be shown for some commonly used radiopharmaceuticals, calculated using the new ICRP data set (Publication 133). These values will be compared with those of ICRP Publication 128 (2015) and potential differences will be discussed. 2). Organ

and effective dose coefficients for non-reference persons will be calculated using the respective SAFs, previously obtained with Monte Carlo methods. 3) Organ and effective dose coefficients for the non-reference persons will be calculated using the SAFs of ICRP Publication 133 based on reference phantoms and by applying the mass scaling assumption. These will be compared with those calculated as in (2). The accuracy of the calculations when applied to a real patient rather than the standard individual will be discussed.

OP-667

IDAC-Dose 2.1, an internal dosimetry program for diagnostic nuclear medicine using the official ICRP specific absorbed fractions for the adult ICRP/ICRU reference computational voxel phantoms

M. Andersson[1], L. Johansson[2], K. Eckerman[3], S. Mattsson[1]; [1]Medical Radiation Physics, Malmoe, SWEDEN, [2]Department of Radiation Sciences, Umeå, SWEDEN, [3]Center for Radiation Protection Knowledge, Oak Ridge National Laboratory, Oak Ridge, TN, UNITED STATES OF AMERICA.

Aim and Background: Committee 3 of the International Commission on Radiological Protection (ICRP) Task Group 36 estimates of absorbed dose in organs and tissue and the effective dose to patients from various radiopharmaceuticals to date have been derived using the computed program Internal Dose Assessed by Computer (IDAC). IDAC-Dose 1.0 has been used to perform the dose calculations based on photon specific absorption fractions (SAF) simulated from the mathematical phantoms created by Cristy and Eckerman in 1987. To improve the accuracy of the calculations, ICRP has now adopted a more realistic voxel phantom to incorporate in Monte Carlo (MC) simulations of new photon, electron and alpha SAF-values. The internal dosimetry computer program, IDAC-Dose, has been substantially upgraded (IDAC-Dose 2.1) and incorporates these SAF-values (ICRP 133) for calculations of the absorbed doses and the effective dose. **Material & Methods:** With IDAC-Dose 2.1 it is possible to calculate the dose from 1252 different radionuclides. The program uses the latest biokinetic models and assumptions of the ICRP TG 36, which also includes the incorporation of the Human Alimentary Tract Model (ICRP 100) and the latest tissue weighting factors (ICRP 103). The S-values are generated through mono-energetic photon, electron and alpha SAF-values given in ICRP Publication 133 generated for the adult voxel phantoms and decay data of ICRP publication 107. The IDAC-Dose 2.1 has 83 source regions where activity uptake can be placed and the program calculates the mean absorbed dose to 43 different organs and tissues. IDAC-Dose 2.1 has been harmonized with the other ICRP sanctioned computer program Dose and Risk Calculation (DCAL), which is used to estimate doses for occupational intakes of radionuclides. **Results & Conclusions:** The harmonization between IDAC-Dose and DCAL mean that there is no longer any difference in the dose calculations between decays calculated with radiopharmaceuticals or radionuclides decaying in occupational, public or environmental situations. With the update of the IDAC-Dose 2.1, more realistic absorbed dose estimations can be performed on adults and enables the implementation of the effective dose estimations defined in the ICRP Publication 103.

OP-668

Image based preclinical absorbed dose estimation through GATE Monte Carlo simulation using ^{18}F-FDG PET/CT images of mice

A. Gupta[1], M. S. Lee[1], J. H. Kim[2], S. H. Park[3], H. S. Park[3], S. E. Kim[3], D. S. Lee[1], J. S. Lee[1]; [1]Seoul National University (SNU), Seoul, KOREA, REPUBLIC OF, [2]Korea Research Institute of Standards and Sciences, Daejeon, KOREA, REPUBLIC OF, [3]Graduate School of Convergence Science and Technology, Seoul, KOREA, REPUBLIC OF.

Purpose: High level of accuracy in internal dosimetry is essential to obtain appropriate absorbed dose response-effect relationships during preclinical research. Due to the various limitations associated with organ level MIRD based dosimetry (MBD) methods, the voxel based dosimetry (VBD) which contributes to a more accurate assessment of absorbed dose has become essential. Recently, the GATE Monte Carlo (MC) simulation has gained attention in preclinical VBD application. In this study, we used real PET/CT images of mice to estimate absorbed dose using GATE MC and compared with MBD to evaluate the feasibility of GATE image-based dosimetry. **Subjects and Methods:** PET/CT imaging of C57BL/6 mice (n=4, body weight: 30.49 ± 3.62 g) in overnight fasting condition were performed using nanoScan PET/CT. Dynamic PET images were acquired in list mode for 90 min followed by a CT acquisition after IV injection of 13.50 ± 3.54 MBq of ^{18}F-FDG. GATE MC toolkit was applied to estimate absorbed dose in various organs of mice using real CT and PET images as voxelized phantom and voxelized source respectively as the input for simulation. Absorbed dose was calculated from dosemaps obtained as an output of GATE simulation using 3D VOIs drawn on organs in CT and PET images. MIRD based absorbed dose were also calculated using published S-values which were based on Moby phantom (Xie *et al* 2012 *Phys. Med. Biol.*). Organ mass correction was performed for MIRD based method. Absorbed dose estimated from GATE and the MIRD methods were compared and relative percentage differences were reported. **Results:** GATE based absorbed dose (mGy/MBq) were estimated and compared to MIRD based absorbed dose which showed comparable results. The percentage difference in brain, heart, liver, lungs, stomach, spleen, kidneys and urinary bladder were 24.32%, 9.33%, -1.72%, -73.16%, 4.78%, 17.27%, 24% and 29.52% respectively. The absorbed dose in lungs was highly overestimated by MIRD method. This was due to the difference in mass and anatomical position of lungs in Moby and real mice. The average percentage difference between GATE and MIRD method was < 5%. GATE MC simulation provided individualized absorbed dose based on specific activity distribution in each mouse when using real PET/CT images. **Conclusion:** Voxel based absorbed dose estimated by GATE simulation using real mouse imaging data would be more accurate and mouse specific. Hence, this method can be used in targeted radionuclide therapy for personalized dosimetry.

OP-669

Radiation dosimetry of the tau PET Tracer ^{18}F-PI-2620 in humans

J. Seibyl[1], O. Barret[1], A. Stephens[2], J. Madonia[1], D. Alagille[1], A. Mueller[2], H. Schieferstein[2], M. Berndt[2], H. Kroth[3], S. Bullich[2], C. Papin[1], V. Carroll[1], C. Sandiego[1], A. Pfeifer[3], A. Muhs[3], L. Dinkelborg[2], G. Tamagnan[1], K. Marek[1]; [1]Molecular Neuroimaging, New Haven, CT, UNITED STATES OF AMERICA, [2]Piramal Imaging, Berlin, GERMANY, [3]AC Immune SA, Lausanne, SWITZERLAND.

Introduction: Intracellular tau deposition is a key pathologic feature of Alzheimer's disease (AD) and other neurodegenerative disorders. Recently, positron emission tomography tau probes have been developed for in vivo detection of brain tau load, although quantification is challenging due to high off target binding and slow kinetics. Further, different tau radiotracers have different affinities for tau species. ^{18}F-PI-2620 is a novel tracer with a high affinity for binding to aggregated tau that has shown high signal in brain regions of expected tau pathology in AD and PSP subjects in an initial clinical study. The purpose of this study was to determine the biodistribution and radiation dosimetry of ^{18}F-PI-2620 in humans. **Subjects & Methods:** 6 subjects (3 male, 3 female, mean age 31 ± 9 yrs) were injected with a a single bolus of ^{18}F-PI-2620 (mean dose 354 ± 5 MBq) followed by serial whole body PET imaging scans of up to 6 hours. Urine samples collected over the imaging period were evaluated to measure the excretion of ^{18}F-PI-2620 through the urinary tract. Time-dependent source organ counts were assessed based on individualized VOIs and residence times were calculated using the area under the time-activity curve method. Radiation absorbed dose estimates based on the MIRD methodology utilizing urine data and International Commission on Radiological Protection (ICRP 30) gastrointestinal tract kinetics were determined. **Results:** ^{18}F-PI-2620 shows elimination mainly via the hepatobiliary route with some minor elimination by the urinary pathway. Target organs with highest effective dose are gallbladder wall and upper large intestine. The Effective Dose per 185 MBq (5 mCi) injection is 4.1 mSv with no bladder voiding, and 4.0 mSv with 2 hour bladder voiding interval for an adult male. **Conclusion:** The radiation dosimetry of ^{18}F-PI-2620 is suitable for human use and is similar to other ^{18}F-labelled radio-pharmaceuticals.

Preliminay Results of Biodistribution and Dosimetric Analysis with [^{68}Ga]Ga-DOTA[ZOL]: A new bone seeking PET radionuclide

A. Khawar[1], E. Eppard[1], H. Ahmadzadehfar,[1], S. Kürpig[1], M. Meisenheimer[1], F. C. Gaertner[1], F. Roesch[2], M. Essler[1], R. A. Bundschuh[1]; [1]Department of nuclear medicine, University Hospital, Bonn, GERMANY, [2]Institute for nuclear chemistry, Johannes Gutenberg-University, Mainz, GERMANY.

Purpose/Introduction: Recently [^{68}Ga]Ga and [^{177}Lu]Lu DOTA labelled hydroxy-bisphosphonates have been proposed as new theranostic agents for metastatic skeletal disease. Animal studies have shown pharmacokinetics of [^{68}Ga]Ga-DOTA[ZOL] with high skeletal uptake and fast clearance from blood pool better than [^{18}F]NaF. This study aims at first in human biodistribution and dosimetric analysis of [^{68}Ga]Ga-DOTA[ZOL]. **Subjects & Methods**: A total of three patients (mean age: 77yr) having metastatic skeletal disease with refractory prostate carcinoma (male) and breast carcinoma (female) patients were included in this study. Patients were injected [^{68}Ga]Ga-DOTA[ZOL] intravenously (150-185MBq). All patients underwent an initial dynamic imaging of the abdomen for 30 min (list mode) followed by static PET/CT imaging (skull to mid-thigh) at 45 min and 2 h with a Siemens Biograph 2 PET/CT camera. For qualitative and quantitative analysis dynamic images were reconstructed as 6 images of 300s. Source organs were identified on qualitative analysis. Source organs VOI's were drawn on CT image and KBq/ml counts from PET image were determined using MEDISO interview fusion software. Time integrated activity coefficients were generated for source organs, marrow and urinary bladder. Organ absorbed doses and effective doses were calculated using OLINDA/EXM after applying a correction factor for patient weight. **Results:** Qualitative analysis revealed intense tracer uptake in kidneys, urinary bladder, skeletal tissue and faint uptake in liver, spleen and salivary glands. High bone to soft tissue as well as tumor to bone uptake was found. Quantitative time activity analysis showed rapid blood clearance, early uptake and fast clearance from kidneys and maximum uptake in bone achieved in less than half an hour followed by gradual decline on average. The measured effective dose was 0.016 mSv/MBq, with the urinary bladder, osteogenic cells, kidneys and red marrow receiving the highest doses of 0.22, 0.037, 0.036 and 0.026 mSv/MBq, respectively. 150 MBq of [^{68}Ga]Ga-DOTA[ZOL] results in 2.38 mSv of effective dose. **Conclusion:** These first results are showing that [^{68}Ga]Ga-DOTA[ZOL] with favourable bio kinetics and modest radiation exposure is a promising new bone seeking theranostic agent that can be labelled with [^{177}Lu]Lu for theranostic purposes. However, further large studies are required.

OP-671

PET-based human dosimetry of ^{68}Ga-NODAGA-exendin-4, a tracer for beta cell imaging

M. Boss, M. Buitinga, T. J. P. Janssen, M. Brom, E. P. Visser, M. Gotthardt; Radboud University Medical Center, Nijmegen, NETHERLANDS.

Background: The stable glucagon-like peptide-1 (GLP-1) analogue exendin-4 specifically binds the GLP-1 receptor. ^{68}Ga-NODAGA-exendin-4 is a promising tracer for beta cell imaging using PET/CT with a wide range of possible applications. In patients with insulinoma, ^{68}Ga-NODAGA-exendin-4 PET/CT shows promising results in tumour visualization. Furthermore, this technique can contribute to the knowledge of the role of beta cell mass in the pathofysiology of type 1 and type 2 diabetes (T1D, T2D, respectively). Also therapeutic approaches in diabetes, like islet transplantation in patients with T1D and remission of T2D after Roux- and Y gastric bypass can be examined using this novel tracer. Calculating the radiation dose from ^{68}Ga-NODAGA-exendin-4 is important for use in patients, to estimate the possibility of repeated PET scans to follow disease progression,

and the possibility for use in children. **Methods:** 6 patients with hyperinsulinemic hypoglycaemia (2 men, 4 women, mean age ± SD: 54.0 ± 15.5 y, mean weight ± SD: 77.1 ± 11.2 kg) were included. After intravenous injection of the tracer (105.6 ± 2.3 MBq), 4 successive PET/CT scans were obtained at 30, 60, 120 and 240 minutes post injection on a Siemens Biograph mCT-40 time-of-flight PET/CT scanner. Images were acquired of 2 bedpositions including liver, pancreas and kidneys at 10 min per bedposition and analyzed using Inveon Research Workplace software. Volumes of interest were drawn over the pancreas and kidneys and tracer activity in the remainder of body was determined. Time-integrated activity coefficients were calculated and OLINDA/EXM version 1.1 software was applied to calculate radiation doses using the reference adult male and female models. **Results:** Highest uptake was in the kidneys and pancreas. The mean effective doses were 24.6 ± 5.5, and 1.2 ± 0.4 µSv/MBq respectively. The effective dose was 32.0 ± 6.1 µSv/MBq. **Conclusion:** When using the radiopharmaceutical 68Ga-NODAGA-exendin-4 the kidneys are the dose-critical organs, which receive the highest radiation dose of 24.6 ± 5.5 µSv/MBq. The kidney dose will thus be well below 1Gy after injection of 100 MBq of 68Ga-NODAGA-exendin-4. For this injected activity , the expected effective radiation dose is 3.2 ± 0.6 mSv. This dose could be diminished in the future by optimizing protocols leading to possible reduction of injected activity. The here calculated doses show that 68Ga-NODAGA-exendin-4 can be safely used for imaging and are promising for the possibility of the use of this tracer in children in which we expect a similar biodistribution of the tracer.

PET-based biodistribution and radiation dosimetry of [64Cu]copper dichloride, first-in-human healthy volunteer evaluation

M. A. Avila-Rodriguez[1], *C. Rios*[2], *J. Carrasco-Hernández*[1], *J. Manrique-Arias*[1], *R. Martinez-Hernández*[2], *E. Martínez-Rodríguez*[2], *F. O. García-Pérez*[3], *M. Romero-Piña*[3], *A. Jalilian*[4], *A. Díaz-Ruiz*[2]; [1]*Universidad Nacional Autónoma de México, CDMX, MEXICO,* [2]*Instituto Nacional de Neurología y Neurocirugía, CDMX, MEXICO,* [3]*Instituto Nacional de Cancerología, CDMX, MEXICO,* [4]*International Atomic Energy Agency, Vienna, AUSTRIA.*

Purpose/Introduction: In recent years Copper-64 in the chemical form of copper dichloride ([64Cu]CuCl$_2$) has been identified as a potential agent for PET imaging and radionuclide therapy targeting the human copper transporter CTR1, which is overexpressed in a variety of cancer cells. Future clinical applications of [64Cu]CuCl$_2$ will require of accurate dosimetric data, especially for therapeutic procedures; however, limited human biodistribution and radiation dosimetry data is available for this tracer. The aim of this research was to determine the biodistribution and estimate the radiation dosimerty of [64Cu]CuCl$_2$, using whole-body (WB) PET scans in healthy volunteers. **Subjects & Methods:** Six healthy volunteers were included in this study (3 women and 3 men, 54.3±8.6 y, mean weight 77.2 ± 12.4 kg). All of them signed an informed consent. After I.V. injection of the tracer (4.0 MBq7kg), 3 consecutive whole-body (WB) emission scans were acquired at 5,

30, and 60 min after injection. Additional scans were acquired at 5, 9 and 24 h post-injection. Low-dose CT scan without contrast was used for anatomic localization and attenuation correction. OLINDA/EXM software was used to calculate human radiation doses using the reference adult model. **Results:** The injection of 310±50 MBq of [64Cu]CuCl$_2$ solution in physiological saline produced no observable adverse events or clinically detectable pharmacologic effects in any of the 6 subjects. The highest uptake was in the liver, followed by lower and upper large intestine walls, and pancreas, in descending order. Elimination by urine was negligible. The critical organ was liver with a mean absorbed dose of 421±56 µGy/MBq for women and 310±67 µGy/MBq for men, while the mean effective doses were 61.8±5.2 µSv/MBq for women and 51.2±3.0 µSv/MBq for men. **Discussion/Conclusion:** To the best of our knowledge this is the first report on biodistribution and radiation dosimetry of [64Cu]CuCl$_2$ in healthy volunteers. Capasso et al. (Ann. Nucl. Med. 2015;29:482-8) obtained human biodistribution data from patients with prostate cancer and estimated dosimetric values, reporting the liver as the critical organ with a mean absorbed dose of 294 µGy/MBq, and a mean effective dose of 33.8 µSv/MBq. Note that these values are underestimated in comparison with the values obtained for healthy volunteers. However, the discrepancy could be explained by the altered biodistribution of copper in patients, as the uptake of [64Cu]CuCl$_2$ in the tumor, reduces the amount of radiotracer available for other organs and tissues. Research supported by CONACYT 233815, and International Atomic Energy Agency RC20569.

OP-673

Validation of semi Monte Carlo, voxel-based radionuclide dosimetry software using 3D printed phantom experiments with TLD measurements and patient indium-111 Exendin scans using SPECT/CT

W. D. Wormgoor[1], *A. P. W. Meeuwis*[2], *I. Sechopoulos*[2], *E. Hippeläinen*[3], *A. Sohlberg*[4], *E. P. Visser*[2]; [1]*ZGT, Hengelo, NETHERLANDS,* [2]*Radboud University Medical Center, Nijmegen, NETHERLANDS,* [3]*University of Helsinki and Helsinki University Hospital, Helsinki, FINLAND,* [4]*Joint Authority for Päijät-Häme Social and Health Care, Lahti, FINLAND.*

Purpose: The purpose of this study is to validate an experimental software package for patient-specific, voxel-based radionuclide dosimetry using both patient SPECT-CT data and another dosimetry software, and using measurements with a 3D printed phantom and thermoluminescent dosimeters (TLD). **Subjects & Methods:** A program based on semi-Monte Carlo simulations (sMC) (Hermes Medical Solutions, Stockholm, Sweden) was used to estimate the dose distributions from 18 patient 111In-Exendin SPECT-CT scans, each consisting of 3 or 5 acquisitions. The resulting mean kidney dose estimates were compared to those obtained using OLINDA/EXM 1.1 from the same SPECT-CT acquisitions. A previously developed 3D printed phantom of the pancreas and kidneys inside a shell of a NEMA IEC body phantom was filled with aqueous 111In-chloride solutions of different activity concentrations in the background and in the organs. Dose distribution estimates for both the photon and electron contribution were obtained with the sMC software of a time series of 5

SPECT-CT scans of the phantom. The absorbed dose as a result of the photon contribution was compared with local dose measurements performed using TLDs at 16 locations inside the phantom. **Results:** The mean kidney doses in the patient studies obtained using the sMC software correlated strongly with the values from OLINDA/EXM (slope = 0.86, R^2 = 0.92). The phantom study resulted in a photon contribution in the sMC software that was 1.52 times higher (SD = 0.37) than the absorbed dose as measured by the TLDs (mean factors of 1.5, 1.3, 1.8, for kidneys, pancreas and background, respectively). **Discussion / Conclusion:** Electron absorption in the walls of the phantom organs and a sub-voxel inhomogeneity could explain part of the difference between the software and the TLD measurements. Furthermore, the TLD calibration could be affected by the electrons emitted by [111]In. Therefore, further work is needed to quantify these factors and to validate the TLD measurements. Although good agreement was obtained when comparing software-based estimates, the experimental validation led to differences that could not be fully explained and need to be validated further.

Clinical Evaluation of Data-driven Motion Correction for PET Imaging

C. F. Uribe[1], E. Rousseau[1], F. Lacroix-Poisson[1], T. Alden[1], S. Wollenweber[2], F. Benard[1]; [1]BC Cancer Agency, Vancouver, BC, CANADA, [2]GE Healthcare, Waukesha, WI, UNITED STATES OF AMERICA.

Aim: Respiratory motion degrades the ability to detect and quantitate lung/abdomen lesions using PET. Our purpose was to evaluate data driven gating (DDG) as an approach to perform respiratory motion correction, and validate it in comparison to conventional device-based gating methods. **Methods:** Sixteen patients with liver, lung, esophageal, or gastric cancer underwent an FDG-whole-body PET/CT scan on a GE-Discovery 690 PET/CT scanner. Three methods were used to measure the respiratory waveform: 1) infrared camera with a reflective block on the abdomen, 2) a combination of data from a pressure and temperature sensors, and 3) DDG based on principal component analysis. Three 75 kBq Na-22 sources were placed fixed on the bed, and moving on the patient's chest. Data was collected over 3 bed positions for 5 minutes each with list mode enabled for retrospective reconstruction. Gated images (8-bins) were created using MATLAB-based tools using the resulting waveforms and three sub-methods: a) phase, b) displacement, and c) equal-duration displacement. Two non-gated images were also created using 100% (NGL) and 1/8 (NGS) of the data in the list file. The latter was to obtain similar statistics between gated images and NGS. Reconstructions were performed with OSEM algorithm (32 subsets, 2 iterations), and scatter/attenuation correction. ROIs were drawn around 17 lesions and sources using a 40% fixed-threshold. Volumes, displacements, SUVmax, SUVmean, and SNR were compared between gated and non-gated images using a nonparametric Kruskal-Wallis test (p=0.05). Additionally, gated images were scored (Likert scale) by two physicians based on lesion identification, noise, motion tracking, and diagnostic improvement. **Results:** Lesion displacement range was within 0.39-1.04 cm with the various methods. No significant differences in volumes (6.7±1.4 mL) were found between gating methods. Gating did not significantly increase SUVmax compared to NGS, but showed an increase of up to 40% with respect to NGL for both lesions and sources. Gating showed 16% and 28% increase in lesion SUVmean compared to NGS and NGL, respectively. For the Na-22 sources using gating, SUVmean increased up to 35% but was only significant with respect to NGL. SNR was 40% lower with respect to NGL but was comparable to NGS. The qualitative analysis demonstrated no difference between different gating methods. **Conclusion:** DDG and the other device-based gating methods were qualitatively and quantitatively similar for use in respiratory gating. Increases in SUV with gating appear to depend on image statistics and lesion displacement range, and this effect is still under investigation.

OP-686

ParaPET, A New Statistical Methodology to Derive 3D Maps of FDG-PET Kinetic Parameters

E. Colard[1], L. Padovani[2], S. Delcourt[3], S. Thureau[4], B. Farman Ara[3], P. Gouel[5], I. Gardin[6], P. Vera[6], D. Taïeb[7], D. Barbolosi[8], S. Hapdey[6]; [1]LITIS QuantIF EA4108, Rouen, FRANCE, [2]Department of Radiotherapy, La Timone University Hospital, Marseille, FRANCE, [3]Department of Nuclear Medicine, La Timone University Hospital, Marseille, FRANCE, [4]Department of Radiotherapy, Centre Henri Becquerel and LITIS QuantIF EA4108, Rouen, FRANCE, [5]Department of Nuclear Medicine, Centre Henri Becquerel, Rouen, FRANCE, [6]Department of Nuclear Medicine, Centre Henri Becquerel and LITIS QuantIF EA4108, Rouen, FRANCE, [7]Department of Nuclear Medicine, La Timone University Hospital and European Center for Research in Medical Imaging (CERIMED), Marseille, FRANCE, [8]SMARTc, INSERM, UMR 911 CR02, Marseille, FRANCE.

Purpose: We extended a statistical method recently proposed by Barbolosi et al. (Barbolosi, MBEC 2016) to generate 3D images of kinetic parameters in FDG PET: PARAPET. The major improvements rely on the integration of a new error model of PET measurement, a non-invasive blood activity measurement (NIBAM) and the measurement of 3D kinetic parameters. **Subjects & Methods**: The PARAPET method requires a late dynamic PET acquisition of 15 minutes centered over the lesion. Five images of FDG mean activity concentration, associated with five images of its variability are generated to model the errors of PET measurements necessary to our statistical approach. To avoid multiple blood samples needed for Barbolosi's method, a late NIBAM is determined from FDG PET images. Regions of interest manually drawn over blood compartment are used to extract the mean blood activity concentration and its variance. Our method is applied on each voxel to derive parametric PET images. Our approach was evaluated and compared to Patlak analysis as a reference. Hunter and Barbolosi methods (with blood samples or with NIBAM) were also investigated and compared to Patlak. Two kinetic parameters were investigated: K_i, the net influx rate and $K_{i,max}$, corresponding to the maximum value of K_i in the lesion. **Results**: The methods were evaluated on 16 non-small cell lung cancer lesions from 8 patients planned for radiochemotherapy included in the on-going ParaPET clinical trial (NCT 02821936). Patients had between 4 to 5 blood samples. Results show that our approach presents an excellent correlation with Patlak (r = 0.99) compared to Hunter (r = 0.94), Barbolosi with blood samples (r = 0.97) or with NIBAM (r = 0.95) methods. The mean errors (± SD) in $K_{i,max}$ estimate were -0.2% ± 10.2% for our approach, 40.5% ± 34.6% for Hunter, -4.9% ± 10.0% for Barbolosi and -1.3% ± 15.5% for Barbolosi with NIBAM. **Conclusion**: Our methodology allows a more accurate estimate of $K_{i,max}$ and is a non-invasive alternative to methods using multiple blood samples, using only a late PET acquisition, easily adaptable to clinical routine. It also proposed to compute a set of kinetic parameters at the voxel level, giving access to additional quantitative information. These preliminary results should be further statistically confirmed with more data. **Research Support**: The author received a grant support for education between the University of Rouen and GE Medical System. The study was also funded by the Cancéropôle PACA and the Centre Henri Becquerel.

OP-687

Assessment of whole-body scatter correction for Ga-68 PSMA PETCT

H. Bal[1], I. Hong[1], F. Buther[2], M. Aykac[1], K. Schaefers[2], M. Conti[1]; [1]Siemens Healthineers, Knoxville, TN, UNITED STATES OF AMERICA, [2]University of Muenster, Muenster, GERMANY.

Introduction*:* Multi-bed PETCT oncology studies are processed bed-by-bed in conjunction with data acquisition for efficient workflow. This process however limits the axial field of view for the scatter estimation to a single bed, leading to possible inaccuracies in the scatter shape. In this work we investigated the performance of whole-body scatter correction (WBSC) relative to single bed scatter correction (SBSC). **Methods***:* A two-bed Monte-Carlo simulation was performed for a hot bladder phantom consisting of a large cylinder containing a hot sphere (250:1 sphere to background ratio) axially centered in the bed overlapping region. Additionally, experimental data using long uniform cylinder phantoms (20 cm diameter and 37 cm diameter) and a hot bladder phantom were acquired using two-bed acquisition. Further, 8 Ga-68 PSMA clinical datasets selected based upon the indication of scatter overcorrection were also chosen for analysis. All data were reconstructed with TOF based OSEM (3it, 21 subsets) using WBSC and SBSC strategies. A background region surrounding the hot sphere was used to compute bias in the activity estimates for the simulated data. For the experimental uniform phantom data axial uniformity was computed as the maximum variation in axial planes. Clinical data were analyzed by computing SUVs in a 3D liver region of interest as well as a region suffering from scatter overcorrection. **Results:** The Monte Carlo results showed that background surrounding the hot bladder was 5% lower with whole-body scatter and 33% lower with single bed scatter relative to simulated background. The uniform phantom study had better axial uniformity with WBSC (3% (20 cm); 9% (37cm)) compared to SBSC (4% (20 cm); 12% (37 cm)). Visual assessment of hot bladder phantom indicated a more uniform background with WBSC compared to SBSC. All patient data demonstrated considerably improved visual image quality with whole-body scatter compared to single bed scatter. In general, SUVs were higher with WBSC compared to SBSC (3% for liver and 400% for scatter overcorrected regions). The pooled data of voxel-wise relative difference showed that 5% data had 50% (or greater) higher quantitative estimates with WBSC compared to SBSC. **Conclusion:** Scatter estimation with WBSC was found to be more accurate compared to SBSC due to extended axial coverage for scatter estimation. This in turn results in higher and more accurate activity estimates with WBSC compared to SBSC while also improving image quality.

OP-688

Impact of motion compensation and partial volume correction on ^{18}F-NaF PET/CT imaging of coronary plaque

J. Cal-Gonzalez[1], C. Tsoumpas[2], M. Lassen[1], S. Rasul[3], M. Hacker[3], K. Schäfers[4], T. Beyer[1]; [1]QIMP group, Center for Medical Physics and Biomedical Engineering, Medical University of Vienna, Vienna, AUSTRIA, [2]Division of Biomedical Imaging, University of Leeds, Worsley Building, LIGHT Labs, LS2 9NL, Leeds, United Kingdom., Leeds, UNITED KINGDOM, [3]Division of Nuclear Medicine, Department of Biomedical Imaging and Image-guided Therapy, Medical University of Vienna, Vienna, AUSTRIA, [4]European Institute for Molecular Imaging, University of Münster, Münster, GERMANY.

Aim: Recent studies suggest that ^{18}F-NaF PET enables visualization and quantification of plaque micro-calcification in the cor-onary tree. However, PET imaging of plaque calcification in the coronary arteries is challenging because of the respiratory and cardiac motion as well as partial volume effects. The objective of this work is to implement an image reconstruction framework, which incorporates compensation for respiratory and/or cardiac motion (MoCo) and partial volume correction (PVC), for cardiac ^{18}F-NaF PET imaging in PET/CT. **Materials and Methods**: Realistic simulations (Biograph TPTV and Biograph mCT) and phantom acquisitions (Biograph mCT) were used. Different uptake values of the plaques (spherical shape, 4 mm diameter) were evaluated in the simulated datasets, with lesion-to-background ratios (LBR) of 10, 20, 50 and 70:1. The experimental phantom included three plaque-type lesions of 18, 31 and 36 mm³ respectively, with a LBR of 70:1. After validation of the MoCo and PVC methods, they were applied to four pilot ^{18}F-NaF PET/CT patient studies. In all cases, the MoCo-based image reconstruction was performed using the STIR software. The PVC was obtained from a local projection (LP) method, previously evaluated in preclinical and clinical PET. We evaluated the noise in the image (measured in a background region) and the lesion-to-background ratio (LBR) values of the plaques, using the maximum (LBR$_{max}$) voxel value within the segmented plaque. **Results**: After applying MoCo and PVC, LBR$_{max}$ increased by 200% to 1110% in the simulated data, by 212% to 614% in the phantom experiments and by 14% to 188% in the plaques with positive uptake observed in the patients. Similar noise values were observed in all images, in contrast to the significantly higher noise observed when using respiratory or cardiac gating. **Conclusions**: A combined MoCo and PVC approach for PET/CT imaging was implemented within the STIR reconstruction framework. The simulated datasets, experimental and patient data show significant improvement in the quantification of small coronary lesions when MoCo and PVC are taken into account. **Acknowledgments:** This work was supported by the EU COST Action TD1007.

OP-689

A phantom evaluation of a commercial algorithm for photopenic artefact reduction in high contrast PET/CT and implications for ^{124}I PET/CT

P. Braad, P. F. Høilund-Carlsen; Department of Nuclear Medicine, Odense University Hospital, Odense C, DENMARK.

Purpose: Overcorrection of scatter in PET/CT images may cause photopenic artefacts in regions close to organs that have a high specific uptake of activity. On the new GE Discovery MI (DMI) PET/CT system (General Electric, USA) a scatter limit is automatically activated during image reconstruction to circumvent this problem. For non-pure positron emitters, e.g. ^{124}I, additional modelling is performed during scatter correction to account for prompt gamma coincidences (PGCs). The present phantom study aimed to validate the photopenic artefact reduction algorithm with ^{68}Ga and ^{124}I on the new DMI system. **Methods**: ^{124}I (1-50 MBq) was distributed to the spheres, background, and lung insert of the NEMA/IEC torso phantom. Scanning was performed on the DMI with and without PGC correction. Images were visually assessed. Contrast recovery, background variabil-

ity and the accuracy of activity quantification in the phantom background were measured at a sphere-to-background ratio of 5 and at lung-to-background activity ratios (LBR) of 0, 40, 120, 400, and 1200. Similar scans and subsequent analyses were performed with [68]Ga. All scans were repeated on the GE Discovery 710 (D710) PET/CT system and results compared to those obtained on the DMI. **Results:** With ^{68}Ga and [124]I, scatter appeared undercorrected on both the DMI and D710. A positive bias on activity quantification in the phantom background caused a contrast reduction between the spheres and the background at high LBRs. No spheres were visible at a LBR of 1200, the 3 ([124]I) to 4 (^{68}Ga) largest spheres could be identified at a LBR of 400 whereas all spheres were visible with both ^{68}Ga and [124]I at lower LBRs. The image quality was superior, background variability lower, and activity quantification more accurate on the DMI compared to the D710. With ^{68}Ga there were no photopenic areas or any appreciable difference between results obtained with and without PGC-correction. PGC-correction on the DMI also had no noticeable impact on [124]I-images. Photopenic areas were localized around the hot lung insert at LBRs > 40. However, these artefacts only had a minor impact on sphere detectability. Without PGC-correction enabled on the D710, scatter was significantly overcorrected in the center of images which caused large photopenic areas around the hot lung insert. PGC correction acceptably solved the problem. **Conclusion:** The new GE Discovery MI PET/CT system provides acceptable activity quantification accuracy and image quality under challenging imaging conditions where high organ-to-background activity ratios stress the accuracy of scatter correction algorithms.

OP-690

Evaluation of respiratory motion correction in PET/CT using a 3D printed phantom

J. H. Vilsbøll[1], S. W. Hasler[1], L. D. L. Duchstein[2], J. E. Wilhjelm[1], M. N. Lonsdale[2]; [1]Technical University of Denmark, Copenhagen, DENMARK, [2]Bispebjerg and Frederiksberg Hospital, Copenhagen, DENMARK.

Objective: Respiratory movement during PET/CT scan causes blurred images and misalignment between the two modalities. The aim of this study was to evaluate the performance of two motion correction algorithms, Q.Static (rejection of events during inhalation) and Q.Freeze (5 bin gated acquisition with subsequent alignment of PET and CT bins) in combination with an advanced PET reconstruction algorithm, Q.Clear. **Methods:** A 3D printed phantom was designed with six cylindrical holes of varying diameter (3mm, 6mm and 10mm) and filled with 18F-FDG. The phantom was fixed on a motor simulating breathing cycles of a patient during a PET/CT study. Data was acquired on a GE Discovery 710 PET/CT equipped with a Varian RPM respiratory gating system. PET acquisition was done in listmode with motion tracking. CT was acquired as gated CT cine and conventional helical CT. PET data was reconstructed (using Q.Clear) with Q.Static and Q.Freeze for motion correction. As recommended for clinical studies, PET Q.Freeze bin 50% and bin 70% were combined with neighboring CT cine bins (40%/60%

and 60%/80%, respectively). Q.Static PET was compared with the conventional helical CT. Using the known dimensions of the phantom, the extent and pixel values of the hot spots in the PET images and the misalignment (mean difference between center of hot spots) between PET and CT were evaluated. **Results:** The best alignment was found with PET Q.Freeze 50%/CT cine 40%, and PET Q.Freeze 70%/CT cine 60%. Compared to Q.Static/helical CT, misalignment dropped from 13.8mm to 2.7mm. A good match between bins in Q.Freeze PET and CT cine is crucial - misalignment for suboptimal matching was three times higher than for PET Q.Freeze 70%/CT cine 60%. The size of the hot spots in axial PET images was robust and more or less independent of reconstruction or slice location. Furthermore, intensity of the hot spots was reduced in Q.Freeze reconstructions, and the highest intensities were found in Q.Static reconstructions. **Conclusion:** These results show that motion correction with Q.Freeze reconstruction is effective and performs better than Q.Static, but the matching of bins and decrease in intensity is important to keep in mind.

OP-691

Evaluation of the Impact of Using TOF Technique on Metal Artifact Reduction in PET/CT Images

R. Sharifpour[1,2], P. Ghafarian[3,4], M. R. AY[1,2]; [1]Department of Medical Physics and Biomedical Engineering, Tehran University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF, [2]Research Center for Molecular and Cellular Imaging, Tehran University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF, [3]Chronic Respiratory Diseases Research Center, National Research Institute of Tuberculosis and Lung Diseases (NRITLD), Shahid Beheshti University of Medical Sciences, Tehran, Tehran, IRAN, ISLAMIC REPUBLIC OF, [4]PET/CT and Cyclotron Center, Masih Daneshvari Hospital, Shahid Beheshti University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF.

Purpose: The potentials of new technique like time of flight (TOF) can positively affect metal induced artifact in PET/CT imaging. The aim of this study was to evaluate the impact of TOF reconstruction on reduction of metal artifact in PET/CT images. **Subjects and Methods:** NEMA IEC body phantom with 2:1 activity ratio was used in this study. In the first step, the phantom was adapted to hold an ICD on removable lung insert and in the second step, pacemaker generator was also fastened to the internal wall of phantom. Both ICD and battery generator were placed opposite to the sphere with 13 mm in diameter. The phantom was scanned by Discovery 690 GE PET/CT scanner, equipped with 64-slice CT. The PET images were retrospectively reconstructed using two reconstruction algorithms, including non-TOF (routine protocol in our department: OSEM+PSF with 3iterations, 18subsets, 6.4 mm post-smoothing filter) and TOF (TOF+OSEM+PSF: 2iterations, 18subsets, 6.4 mm post-smoothing filter). All images were quantitatively analyzed using the CT number, SUV_{max} and SUV_{mean}. **Results**: In analysis of hot spheres of phantom, spheres with 13 and 17 mm in diameter more than the other affected by streak artifact. The relative differences of maximum CT number in these two spheres between image with metal artifact and image without metal artifact were

327.0% and 89.8% for 13 and 17 mm sphere, respectively. TOF led to increase in SUV_{max} for all spheres except for 13 and 17 mm spheres. In these spheres that strongly affected by streak artifact, TOF decreased the SUV_{max} versus to non-TOF. In place of pacemaker generator and its surroundings a virtual activity was observed, while ICD did not produce any virtual activity. The relative differences of SUV_{max} and SUV_{mean} of the virtual activity between image with metal artifact and image without metal artifact were also considered. The image with a metal artifact that reconstructed using the non-TOF algorithm, demonstrated 71.5% and 54.1% increases in SUV_{max} and SUV_{mean}, respectively, while image with a metal artifact that reconstructed using TOF algorithm, demonstrated 38.3% and 32.7% increases in SUV_{max} and SUV_{mean}, respectively. **Conclusion:** Both the pacemaker generator and ICD produced metal artifact in CT image, but metal induced artifact was only observed for pacemaker generator in PET/CT image. That was interesting that integration of TOF technique to reconstruction, reduced metal induced artifact efficiently so that false positive activity in place of metal and near it, was obviously decreased.

OP-692

Acquisition optimization for Lutetium-177 SPECT quantification

D. M. V. Huizing[1], B. J. de Wit - van der Veen[1], E. J. Rijkhorst[2], M. P. M. Stokkel[1]; [1]Department of Nuclear Medicine, Netherlands Cancer Institute - Antoni van Leeuwenhoek, Amsterdam, NETHERLANDS, [2]Department of Medical Physics and Technology, Netherlands Cancer Institute - Antoni van Leeuwenhoek, Amsterdam, NETHERLANDS.

Introduction: Quantitative imaging in Lutetium-177 (^{177}Lu) therapy is essential for dosimetric analysis. Although in many studies single photon emission computer tomography (SPECT) is performed, there is limited consensus on imaging protocols. In this study the effects of collimators, photopeaks of ^{177}Lu, and scatter and attenuation correction (SC and AC) have been evaluated to optimize acquisition settings for ^{177}Lu-SPECT. **Materials and Methods:** A NEMA 2012/IEC phantom with sphere-to-background ratios of 1:50 and 1:10 was imaged. ^{177}Lu-SPECT acquisitions were performed on a Siemens Symbia at 13 and 20 sec/view in step-and-shoot mode (48 views) equipped with either a ^{99m}Tc/Krypton (Mullekom) or Medium Energy General Purpose (MEGP) collimator. 20% energy windows were positioned around the 113 and 208 keV photopeaks with a 10% downscatter window (reconstructed at 113, 208 and 113+208 keV). All acquisitions were reconstructed using FLASH 3D (10 iterations, 8 subsets) with AC and with or without SC. Calibration factors (CF) were calculated using three large background volumes of interest (VOI), converting counts into kBq/ml. Recovery coefficients (RC) were determined by large VOIs around the spheres and subtraction of background in all acquisitions. Line profiles of the largest sphere (37mm) were created and normalized for activity concentration. **Results:** The background standard deviation for ^{99m}Tc/Krypton ranged from 0.07-2.09 and 1.63-4.05 kBq/ml for the 1:50 or 1:10 ratios, respectively, and from 0.36-1.57 and 0.74-2.90 kBq/ml for MEGP. Moreover, better count-statistics were achieved in all MEGP reconstructions, consequently images acquired with the ^{99m}Tc/Krypton appear to have more noise. The RC-curves showed severe underestimation for spheres smaller than 17mm in all acquisitions. For 1:50 and 20 sec/view with either MEGP or ^{99m}Tc/Krypton the 13mm sphere was still accurately quantified. Due to low count-statistics 113 keV reconstructions proved less suitable for quantification. High contrast images for visual evaluation were obtained using the AC+SC 208 keV photopeak, as shown by line profiles. However, for quantification the 208 or 113+208 keV peak without SC might be more suitable given the arbitrary correction choices that some SC algorithms produce resulting in overestimation of counts by as much as 50%. **Conclusion:** For ^{177}Lu-SPECT, high contrast images suitable for quantification can be best obtained with the MEGP collimator for the Siemens Symbia at 13-20 sec/view (20% window around 208 keV photopeak) with attenuation correction. The MEGP and ^{99m}Tc/Krypton collimator perform similarly in visual assessment and quantification, yet ^{99m}Tc/Krypton has a lower signal-to-noise ratio and MEGP is more sensitive.

Injected Mass is a Limiting Factor for Small Animal PET Studies Using High-Affinity Radioligands: Evidence from a Study Using [11C]- and [18F]Fallypride

M. Toth[1], S. Nag[1], Z. Jia[1], J. Haggkvist[1], J. Mukherjee[2], A. Varrone[1], C. Halldin[1]; [1]Karolinska Institutet, Stockholm, SWEDEN, [2]University of California-Irvine, Irvine, CA, UNITED STATES OF AMERICA.

Introduction: The aim of this study was to show that extra caution should be taken with regards to the injected mass of high-affinity radioligands in small animal positron emission tomography (PET) studies. To examine the relationship between injected mass and receptor availability in mice we have used the structurally identical [^{11}C]- and [^{18}F]fallypride high affinity (0.2 nM) dopamine D_2/D_3 antagonist radioligands. Materials and Methods: [^{18}F]Fallypride was administered intravenously in a high specific radioactivity (SA) condition (45 ± 11 GBq/μmol) and low SA condition (21 ± 5 GBq/μmol) in C57BL/6J mice. To administer the same high-affinity ligand with much lower mass [^{11}C]fallypride was used with SA (153 ± 82 GBq/μmol) that was ~3 times higher than the high SA of [^{18}F]fallypride. Each animal underwent three dynamic PET measurements within two weeks with at least 1 day between the different conditions. The outcome measure was the non-displaceable binding potential (BP_{ND}) obtained with Logan graphical analysis and cerebellum as reference region. Results: BP_{ND} was 13.5 ± 1.1 for the [^{11}C]fallypride experiments. BP_{ND} obtained with [^{18}F]fallypride was 8.6 ± 2.2 with the high SA condition and 5.3 ± 1.3 with the low SA condition. The corresponding injected masses were 0.05 ± 0.04

µg with [^{11}C]fallypride, 0.11 ± 0.03 µg and 0.21 ± 0.05 µg with [^{18}F]fallypride (high SA and low SA condition respectively). BP_{ND} showed a strong negative correlation with injected mass (R2 = 0.95, P < 0.05). Conclusion: The advantage of fluorine-18 radioligands is the possibility of long distance transportation or multiple injections from one production. However, for PET studies in mice with high-affinity radioligands the amount of injected ligand is important due to the lower amount of available binding sites per gram of tissue compared with non-human primates and humans. Therefore, radioligands with high affinity such as [^{18}F]fallypride should be used in mice with precaution and specific attention to SA and mass injected.

OP-694

Quantitative PET of GABA-A receptor binding in gerbils after intra-peritoneal F-18-Flumazenil injection does not resemble accurate results obtained in rats after intravenous administration

M. Mamach[1,2], M. Kessler[1,2], J. P. Bankstahl[1], T. L. Ross[1], F. M. Bengel[1], L. Geworski[1], G. M. Klump[3,2], G. Berding[1,2]; [1]Hannover Medical School, Hannover, GERMANY, [2]Cluster of Excellence Hearing4all, Hannover/Oldenburg, GERMANY, [3]University of Oldenburg, Oldenburg, GERMANY.

Aim: Changes in the inhibitory GABAergic neurotransmitter system are of major importance in hearing disorders. This study aims to adapt and transfer established quantitative measurements of GABA-A-receptors with F-18-Flumazenil (FMZ) PET in rats to the Mongolian gerbil, which is a preferred animal model for hearing research due to its audio frequency range similar to humans. **Methods:** We compared PET results in 12 Sprague Dawley rats to those in 4 gerbils. 10-20 MBq FMZ were injected intravenously (IV) in the tail vein of rats. Gerbils were injected intraperitoneally (IP) as species specific adaptation. All animals were anesthetized using isoflurane. Scans were acquired using a Siemens Inveon PET system for 45min in rats and 60min in gerbils - to account for transfer time of tracer from the peritoneal to blood space. Frames of uptake with consecutively increasing duration were reconstructed iteratively (OSEM3D): 5x2s, 4x5s, 3x10s, 8x30s, 5x60s, 4x5min plus 1x5min, 1x10min in rats and 3x10min in gerbils. Co-57-transmission scans were employed for attenuation correction. PMOD3.6 software was used for motion correction and bio-kinetic modeling utilizing Logan plot (LP) and 2-tissue-compartment-models (2T) with an image derived input function (IDIF) of the left ventricle. Values of non-displaceable binding potentials (BPnd) for auditory cortex (AC) and inferior colliculus (IC), were calculated using pons as a reference region in rats and cerebellum in gerbils. **Results:** Besides slow tracer clearance from the peritoneal space, whole body bio-distribution was similar after both types of application. IV injection showed faster distribution in rats (left ventricle peak ≈2min, brain tissue peak ≈4min) than IP injections in gerbils (ventricle peak ≈4min, tissue peak ≈9min). The modeling approaches yielded comparable BPnds in rats in AC (LP: 1.35±0.35; 2T: 1.20±0.35) and IC (LP: 1.38±0.25; 2T: 1.31±0.30). However, BPnds in gerbils were considerably lower and showed a larger variation with both models in AC (LP: 0.09±0.14; 2T: 0.20±0.20) and in IC

(LP: 0.22±0.20; 2T: 0.45±0.20). **Conclusions:** Flumazenil allows to display GABA-A receptor binding in rats and gerbils. However, there are differences in bio-kinetic between IV and IP application, i.e. delayed kinetics after IP Injection. As a result quantitative measures of GABA-A receptor binding could not be determined with sufficient accuracy after IP application. The standard deviation of the mean BPnds approached up to 29% after IV and 156% after IP injection. The present data suggests the need to explore IV injections in gerbils as a sound basis for quantification of GABA-A receptor binding.

OP-695

In Silico, Design, Synthesis, Pre-clinical studies of [^{11}CH$_3$]-BTZ-MPP: PET neuroimaging agent for 5-HT$_{1A/1A}$/5-HT$_{1A/7}$ Dimeric Serotonin receptors

P. Jha[1,2], S. Chaturvedi[1], P. P. Hazari[1], S. Pal[1], N. Jain[2], A. K. Mishra[1]; [1]Institute of Nuclear Medicine and Allied Sciences, DRDO, Delhi, INDIA, [2]Indian Institute of Technology, Delhi, Delhi, INDIA.

Purpose: Serotonin receptors (5-HTR) sub-types, 5-HT$_{1A}$ and 5-HT$_7$ are implicated in neurological disorders. These are highly co-expressed in brain regions as heterodimers and represent an important pharmacological target for the treatment of depression, anxiety and mood regulation. 5-HT$_7$R acts as a modulator for 5-HT$_{1A}$R and the formation of 5-HT$_{1A}$R/5-HT$_7$R complex is one of the mechanisms for inactivation and desensitization of 5-HT$_{1A}$R. Imaging of 5-HT$_{1A}$R/5-HT$_7$R complex can be utilized to assess the quantitative and functional aspect of neurological disorders. We report the development of a novel ^{11}C-labelled PET radioligand for targeted imaging of 5-HT$_{1A/7}$ neuroreceptors. **Methods:** The mixed affinity ligand based on methoxyphenyl piperazine (MPP) and benzothiazolone (BTZ) was designed on the basis of physicochemical parameters predicted by ADME and the K$_i$ values reported for similar kind of structures. 3D-structures of 5HT$_{1A/7}$Rs were generated using Homology Modeling and extensively validated through Ramachandran Plot, stereochemical quality parameters, docking and MD. All intermediates and final compound were synthesised and characterized using NMR and Mass Spectrometry. Cytotoxicity studies were performed on HEK cell lines. Labelling conditions were established a prior by reaction of methyl iodide and HPLC profiling was used for characterization. **Results:** Receptor ligand interaction of [CH$_3$]-BTZ-MPP reveals the presence of conserved residues in binding sites of 5HT$_{7/1A}$Rs. The G-Score for dimeric 5-HT$_{1A}$-5-HT$_{1A}$, 5-HT$_7$-5-HT$_7$ and 5-HT$_{1A}$-5-HT$_7$Rs were -11.151, -8.816 and -9.0 respectively, which indicated good binding affinity. The values of logPo/w, logBB and logS were calculated to be 3.9, 0.35 and -3.85 respectively using QikProp. Experimental logPo/w of [^{11}CH$_3$]-BTZ-MPP was 0.26 indicating brain penetration and drug likeliness. Synthesis involved the formation of following intermediates and the respective final molecule: (a)BTZ-Cl (98%), (b) N-BOC-BEA (98%), (c) MPP-N-BOC-BEA (80%), (d) MPP-NH$_2$(99%), (e) secondary amine BTZ-MPP (90%), (e) [CH$_3$]-BTZ-MPP (98%). No significant cytotoxicity was observed at concentration range 1nM - 1mM. Radiolabeling was carried using [^{11}C]-CH$_3$I. Initial in vivo biodistribution

studies showed maximum uptake in brain corresponding to 5.19 %ID/g. Significant uptake in hippocampus (74.94%) and cortex (5.95%) indicate affinity and specificity for the dimeric 5-HT$_{1A/1A}$/5-HT$_{1A/7}$ receptors. The uptake in liver indicate hepatobiliary route of excretion. **Future Work:** The imaging studies to confirm brain uptake and selectivity studies are underway. **Conclusions:** Novel neuroimaging agent based on mixed pharmacophore MPP-BTZ to target dimeric 5-HT$_{1A/1A}$/5-HT$_{1A/7}$Rs was theoretically evaluated, synthesised and evaluated. Initial studies indicate brain penetration and preferential uptake in receptor rich regions. Further work will establish its potential application as radiopharmaceutical for neuro-receptor imaging.

OP-696

Head to head comparison of (R)-[^{11}C]verapamil and [^{18}F]MC225 in non-human primates; tracers for measuring P-gp function at the blood-brain barrier

J. Toyohara[1], *L. Garcia-Varela*[2], *T. Kakiuchi*[3], *O. HIroyuki*[3], *S. Nishiyama*[3], *T. Tago*[1], *D. Vallez-Garcia*[2], *R. Boellaard*[2], *P. H. Elsinga*[2], *H. Tsukada*[3], *G. Luurtsema*[2]; [1]*Tokyo Metropolitan Institute of Gerontology, Tokyo, JAPAN,* [2]*University of Groningen, Groningen, NETHERLANDS,* [3]*Hamamatsu Photonics, Hamamatsu, JAPAN.*

Introduction: A number of substrate for P-glycoprotein (P-gp), such as (*R*)-[^{11}C]verapamil ([^{11}C]VER), has been developed for imaging P-gp function with positron emission tomography (PET). These substrates have high affinity for P-gp and can measure decreased function which results in an increased tracer brain uptake. However, it is not possible to measure over-expression of P-gp function, because the concentration of the tracer at baseline is already extremely low. Recently developed [^{18}F]MC225 is a selective substrate for P-gp with a good metabolic stability and showed higher baseline uptake than that of other P-gp substrates. In addition, [^{18}F]MC225 is a weaker P-gp substrate than [^{11}C]VER. These properties would be suitable for measuring over-expression of P-gp in the brain, which is associated with drug resistance e.g. in case of epilepsy and depression. For clinical application in humans, direct comparison using both tracers in the non-human primate was conducted. **Subjects and Methods:** A total of 12 PET measurements with [^{11}C]VER and [^{18}F]MC225 under baseline and blocking conditions were performed in 3 conscious state male monkeys (*Macaca mulatta*) with arterial blood sampling. The blocking effect of P-gp was evaluated with tarquidar loading at a dose of 8 mg/kg. The total distribution volume (V_T) of both tracers reflects P-gp function and was calculated by Logan graphical analysis using a metabolite-corrected plasma input function. **Results:** The baseline uptake of [^{11}C]VER into the brain was low (standardized uptake value; SUV = 0.5-1) and stable till the end of PET measurements (90 min). After tarquidar infusion, the brain uptake of [^{11}C]VER was significantly increased (SUV = 2-3) and peaked at 10 min after tracer injection, and then gradually decreased to SUV=1.5-2. The baseline uptake of [^{18}F]MC225 was higher (SUV = 1-1.5) than [^{11}C]VER and also stable till the

end of PET measurements (90 min). After tarquidar infusion, the brain uptake of [^{18}F]MC225 was significantly increased (SUV = 2-3) and peaked between 20 and 30 min after tracer injection, and then stable or slight decrease till the end of PET measurements. The whole brain baseline V_T of [^{18}F]MC225 (9.5) was 2.6-times higher than that of [^{11}C]VER (3.6). Inhibition of P-gp resulted in a 3.2-times increase of whole brain V_T (11.5) for [^{11}C]VER. For [^{18}F]MC225, the increase was 1.4-times in the whole brain (13.2). **Conclusion:** Our results confirm previous research with [^{18}F]MC225 in rats and indicates that [18F]MC225 is a suitable tracer for measuring over-expression of P-gp at the human blood-brain barrier.

OP-697

Identification and development of a highly specific monoacylglycerol lipase (MAGL) PET tracer ^{11}C-PF-06809247

C. R. Butler[1], *A. Takano*[2], *S. Nag*[2], *R. Arakawa*[2], **K. P. Maresca**[1], *J. R. Piro*[1], *T. Samad*[1], *D. Smith*[1], *D. Nason*[1], *S. O'Neil*[1], *L. McAllister*[1], *S. Grimwood*[1], *P. Trapa*[1], *T. McCarthy*[1], *A. Villalobos*[1], *C. Halldin*[2], *L. Zhang*[1];* [1]*Pfizer, Inc., Cambridge, MA, UNITED STATES OF AMERICA,* [2]*Karolinska Institutet, Stockholm, SWEDEN.*

Aim: Monoacylglycerol lipase (MAGL) is a serine hydrolase highly expressed throughout the brain. It serves as a key gatekeeper regulating the tone of endocannabinoid signaling. Inhibition of MAGL is known to provide therapeutic benefits pre-clinically for a number of neurological disorders. We are interested in developing a MAGL-specific PET ligand to facilitate clinical characterization and assessment of MAGL inhibitors. Herein, we report [^{11}C]PF-06809247 as a potent and selective PET ligand that demonstrated high specific binding in vivo. **Materials and Methods:** The chemical matter was prioritized based on potency/selectivity, physicochemical, and in vitro pharmacokinetic properties. Specifically, we prioritized based on a set of CNS PET design and selection criteria, consisting of central nervous system PET multi-parameter optimization (CNS PET MPO) score; passive permeability RRCK and multi-drug resistance efflux MDR BA/AB; and brain fraction unbound Fu_b. To assess its viability as an in vivo radiotracer, [^{3}H]PF-06809247 was first prepared and evaluated in rodents for target expression (Bmax) measurement, brain bio-distribution and in vivo specific binding assessment. PF-06809247 was subsequently radiolabeled with [^{11}C] methyl iodide, followed by in vivo non-human primate (NHP) PET imaging. A cynomolgus monkey was scanned (High Resolution Research Tomograph; Siemens) for 120 minutes, at baseline and after pretreatment with a selective MAGL inhibitor. **Results:** Prioritization with aforementioned CNS PET ligand selection criteria followed by a PET-specific structure-activity relationship effort quickly identified PF-06809247 as a promising PET lead. Structurally PF-06809247 is amenable to either [^{3}H] or [^{11}C] labeling. It showed good MAGL potency (IC$_{50}$= 9 nM), high passive permeability (RRCK P$_{app}$ AB= 13.8 x 10^{-6} cm/s), low MDR efflux (BA/AB =1.6) and favorable F$_{u\_b}$ (0.04). Saturation binding of [^{3}H] PF-06809247 in rat and NHP brain homogenates revealed high MAGL expression (B$_{max}$ 75-100 nM) across species, and specific

binding across multiple brain regions (>90%), which could be dose-responsively blocked by a selective MAGL inhibitor. [¹¹C] PF-06809247 NHP PET imaging showed rapid brain uptake and sustained binding throughout the brain, consistent with MAGL distribution. The brain uptake was 2-3% injected dose at peak. A significant reduction of [¹¹C]PF-06809247 binding was observed upon pretreatment with a high dose of selective MAGL inhibitor, demonstrating the target was clearly blocked. **Conclusions:** Using PET ligand design parameters, PF-06809247 was rapidly identified with favorable in vitro attributes for PET radiolabeling. Further evaluation via in vivo NHP studies revealed high specific binding to MAGL. Altogether, these data suggested [¹¹C] PF-06809247 is a promising PET ligand for clinical imaging of MAGL.

OP-698

Development of a radiolabeled ligand targeting 5-HT$_3$ receptors in the brain

A. Takano[1], V. Stepanov[1], M. Svedberg[1], J. Häggkvist[1], L. Tari[1], M. Tóth[1], R. Krasikova[1], N. Amini[1], C. Sanchez[2], C. Bundgaard[2], M. Jessing[2], B. Bang-Andersen[2], C. Halldin[1]; [1]Karolinska Institutet and Stockholm County Council, Stockholm, SWEDEN, [2]H. Lundbeck A/S, Lundbeck Research, Copenhagen, DENMARK.

Introduction: The 5-HT$_3$ receptor is unique among 5-HT receptors since it is a ligand-gated ion channel. The 5-HT$_3$ receptor is considered to be involved in several psychiatric diseases including depression and schizophrenia. In the present study, we aimed to develop a radiolabeled ligand targeting the 5-HT$_3$ receptor and evaluate its preclinical characteristics in *in vitro* autoradiography and *in vivo* PET non-human primates (NHP) and rat brain. **Methods:** [¹¹C]2-(4-methylpiperazin-1-yl)quinazolin-4-amine was synthesized by alkylating the precursor 2-(piperazin-1-yl)quinazolin-4-amine with [¹¹C]MeOTf. *In vitro* autoradiography using [¹¹C]2-(4-methylpiperazin-1-yl)quinazolin-4-amine was performed using postmortem rat, NHP and human brain sections. Specific binding and the blocking effects by the 5-HT$_3$ receptor antagonists; ondansetron and mirtazapine, were measured. NHP PET measurements were performed in two rhesus monkeys at baseline and after pretreatment with 1.0-2.0 mg/kg of mirtazapine. Total distribution volume (V_T) was estimated by the two-tissue compartment model and Logan plot using arterial input function. Small animal PET measurements were performed in four Sprague Dawley rats at baseline and after pretreatment with mirtazapine and the cholinergic nicotinic alpha7 receptor agonist and 5-HT$_3$ receptor antagonist, encenicline. **Results:** [¹¹C]2-(4-methylpiperazin-1-yl)quinazolin-4-amine was successfully radiolabelled in good yield and high radiochemical purity (>99%). Specific [¹¹C]2-(4-methylpiperazin-1-yl)quinazolin-4-amine *in vitro* binding was detected in the hippocampus, amygdala and cortex in coronal rat and human brain sections. Total [¹¹C]2-(4-methylpiperazin-1-yl)quinazolin-4-amine binding was blocked 100% with 10 μM of ondansetron, and mirtazapine in the rat brain. However, there was no *in vitro* binding of [¹¹C]2-(4-methylpiperazin-1-yl)quinazolin-4-amine detected in the NHP brain sections. NHP

PET study showed high brain uptake (approximately 300%SUV at peak). However, no clear blocking effects were seen after pretreatment with mirtazapine. Peripherally, the uptake of the radioligand decreased in salivary gland after pretreatment with mirtazapine. Small animal PET study showed high brain uptake (approximately 200%SUV at peak). However, no clear blocking effects were seen after pretreatment with 5HT$_3$ receptor antagonists. **Conclusions:** It is shown that [¹¹C]2-(4-methylpiperazin-1-yl)quinazolin-4-amine can be used to study the *in vitro* 5-HT$_3$ receptor binding and could be used to evaluate *in vivo* peripheral 5-HT$_3$ receptor binding in salivary glands. However, it did not prove to be useful as an *in vivo* PET radioligand for the brain as no clear blocking effects were seen despite the shown good brain penetration. One possibility is that compounds with higher affinity to the 5-HT$_3$ receptor would be necessary for further development of PET radioligands for 5-HT$_3$ receptor in the brain.

OP-699

Radiosynthesis, initial evaluation and whole-body dosimetry of a beta-secretase (BACE) PET radioligand [¹¹C] PF-06684511 in non-human primates

R. Arakawa[1], L. Chen[2], A. Takano[1], M. A. Brodney[2], J. Dutra[3], V. Stepanov[1], S. Nag[1], S. Doran[3], T. McCarthy[2], C. Nolan[2], A. Villalobos[3], L. Zhang[2], C. Halldin[1]; [1]Department of Clinical Neuroscience, Center for Psychiatry Research, Karolinska Institutet and Stockholm County Council, Stockholm, SWEDEN, [2]Worldwide Research & Development, Pfizer Inc., Cambridge, MA, UNITED STATES OF AMERICA, [3]Worldwide Research & Development, Pfizer Inc., Groton, CT, UNITED STATES OF AMERICA.

Aim: Beta-secretase (BACE) is a key enzyme in the generation of beta-amyloid. BACE inhibitors are being developed to decrease beta-amyloid accumulation in the brain and to reduce the risk of Alzheimer's disease. PF-06684511 was identified by Pfizer as a candidate PET ligand for BACE. PF-06684511 bears structure moieties amenable for both F-18 and C-11 radio-labeling. We have previously reported successful radio-labeling of PF-06684511 with F-18 and desired BACE specific binding and kinetics in non-human primate (NHP) PET imaging with [¹⁸F]PF-06684511. In this study, we aimed to radio-label PF-06684511 with C-11 to develop an alternative BACE radioligand in cases that multiple PET scans in the same day and/or reduced radiation dosage to subjects are desired. [¹¹C]PF-06684511 was evaluated in NHPs with baseline/blocking measurements using a BACE inhibitor, PF-06663195. Additionally, we evaluated the radiation dosimetry of [¹¹C]PF-06684511 and [¹⁸F]PF-06684511 in NHPs with whole-body PET measurements. **Materials and Methods:** Brain PET scans of 120 min were performed in two cynomolgus monkeys twice in each NHP, one at baseline and another after intravenous administration of PF-06663195 (0.266 mg/kg bolus followed with 0.064 mg/hr/kg constant infusion). The total distribution volume (V_T) in brain regions of interest was calculated using two tissue compartment (2TC) model with radiometabolite corrected arterial plasma input function. The target occupancy was estimated using the Lassen plot.

Whole-body PET measurements with [11C]PF-06684511 and [18F]PF-06684511 were performed in two cynomolgus monkeys. The effective doses by both radioligands were estimated with the OLINDA/EXM software using the adult male model. **Results:** [11C]PF-06684511 was successfully radiolabeled with radiochemical yield from 150 to 550 MBq per run and radiochemical purity >99.8%. The brain uptake of [11C]PF-06684511 in NHPs was 2-3.5% injected dose (%ID) at the peak under the baseline condition. After pretreatment with PF-06663195, the brain uptake of [11C]PF-06684511 decreased significantly in all regions. Occupancies were 84.4% and 100.5% in two NHPs respectively. High uptake was shown in the small intestine, liver and brain for both [11C]PF-06684511 and [18F]PF-06684511. The effective dose of [11C]PF-06684511 was 0.0054 mSv/MBq while that of [18F]PF-06684511 was 0.043 mSv/MBq. **Conclusions:** [11C]PF-06684511 demonstrated high brain uptake in NHPs at the baseline and clear blocking effects after the administration of a BACE inhibitor. The radiation effective dose of [11C]PF-06684511 was smaller than that of [18F]PF-06684511. [11C]PF-06684511 was demonstrated to be a promising PET radioligand for BACE.

Predictor factors of 68Ga-PSMA PET/CT positivity in biochemical recurrent Prostate Cancer.

C. Artigas, R. Diamand, A. Peltier, R. Van Velthoven, F. Otte, S. Sideris, T. Gil, Z. Wimana, P. Flamen; Jules Bordet Institut Brussels, Brussels, BELGIUM.

Introduction and Aim: Prostate Specific Membrane Antigen (PSMA) is overexpressed in prostate cancer (PCa). 68Ga-PSMA PET/CT has shown better detection rates than other imaging techniques like Choline-PET/CT in patients with biochemical recurrence (BCR) at low PSA levels. The aim of our study was to analyze if parameters like PSA value, PSA kinetics and other factors are associated with a positive 68Ga-PSMA PET/CT. **Material and Methods:** We retrospectively analyzed a cohort of 248 consecutive 68Ga-PSMA PET/CT performed at our institution for PCa BCR after local treatment with curative intent (surgery, radiotherapy or both) between November 2014 and February 2017. Mean age 70y (range 51-90). Looking for predictors of positivity, multiple parameters were registered: primary treatment modality, prostate weight before treatment, initial PSA, TNM classification, OMS histological classification group, micro and macroscopic positive margins, positive lymph nodes, hormonotherapy at the time of scan, PSA value at scan and PSA kinetics. Median PSA value was 2,31 ng/mL, median PSA doubling time (PSAdt) was 8,45 and median PSA velocity (PSAv) 1,4 ng/mL/year. Statistical univariate and multivariate logistic regression analysis were performed to assess which factors were associated with positive 68Ga-PSMA PET/CT. **Results:** 68Ga-PSMA was positive in 185/248 patients (75%).

117/248 (47%) of them were considered oligometastatic (3 or less pathological foci). In the univariate logistic regression analysis, factors with significantly (p<0,05) increased probability of a positive 68Ga-PSMA PET/CT were: PSA value OR (95% CI) 2,04 (1,62-2,58) p <0,0001; PSAdt 1,47 (1,15-1,89) p 0,0025; and PSAv 2,86 (2,05-3,98) p <0,0001. However in the multivariate analysis only PSAv was a significant predictor of a positive 68Ga-PSMA PET/CT (p <0,0001). Detection rates of 68Ga-PSMA PET/CT in relation to PSAv were 42% (38/90), 82% (32/39), 80% (24/30), and 95% (62/65) in patients with PSAv values of, respectively, 1, 1-2, 2-5 and >5 ng/mL/y. **Conclusion:** This retrospective study shows that PSA value and PSA kinetics (PSAdt and PSAv) are factors significantly associated with an increased probability of a positive 68Ga-PSMA PET/CT. Of those parameters, PSAv was the only independent factor, considering it a strong predictor for a positive 68Ga-PSMA PET/CT (p<0,001).

OP-701

Ga-68 PSMA-11 PET-CT in the Evaluation of Newly Diagnosed Prostate Adenocarcinoma

N. Ergül, **T. F. Çermik**; Istanbul Training and Research Hospital, Istanbul, TURKEY.

Introduction: In newly diagnosed prostate adenocarcinoma (PC) conventional imaging modalities (CIM) like pelvic MRI and bone scintigraphy are used for staging. Ga-68 PSMA ligand PET/CT is an emerging modality to detect the metastatic disease in especially intermediate and high risk PC. In this study we analyzed the contribution of Ga-68 PSMA-11 PET/CT in staging and therapy management of newly diagnosed PC. **Materials and Methods:** A total of 78 patients with biopsy-proven PC who were referred for Ga-68 PSMA-11 PET/CT for primary staging were retrospectively analysed. The patients were divided into risk groups according to the D'amico risk stratification criteria. Some of the patients had underwent pelvic MRI and/or bone scintigraphy also. The findings of Ga-68 PSMA-11 PET/CT were compared to the CIM for staging of the disease. The SUVmax values of the primary tumors were calculated and correlated with Gleason scores and metastatic extent of the disease. **Results:** Of 78 patients 5 patients were in low risk group, 18 patients were in intermediate risk group and 55 patients were in high risk group. In 38 patients no metastasis was found. In 10 patients regional lymph node metastases and in 30 patients distant metastases were detected. In 42 out of 78 patients (53%) Ga-68 PSMA-11 PET/CT changed the staging compared to pelvic MRI and bone scan. There was significant difference between the SUVmax values of the tumors with Gleason score 6 and 7 compared to Gleason 8,9 and 10 (p=0.003). The SUVmax values were significantly different between the patients with no metastasis and patients with regional lymph node or distant metastasis (p=0.02 and p=0.002 respectively). **Conclusion:** Ga-68 PSMA-11 PET/CT is an important imaging modality for primary evaluation of newly diagnosed PC changing the disease stage substantially. Also the SUVmax of the primary tumor has a good correlation with Gleason score and metastatic extent of disease defining the prognosis.

OP-702

Initial Results with 18F-PSMA-1007 in Prostate Cancer Patients with Biochemical Recurrence

F. L. Giesel[1], L. Will[1], J. Cardinale[2], O. C. Neels[2], J. P. Radtke[3], K. Kopka[2], U. Haberkorn[1], C. Kratochwil[1]; [1]Department of Nuclear Medicine, University Hospital Heidelberg, Heidelberg, GERMANY, [2]Division of Radiopharmaceutical Chemistry, German Cancer Research Center (dkfz), Heidelberg, GERMANY, [3]Department of Urology, University Hospital Heidelberg, Heidelberg, GERMANY.

Purpose: Prostate cancer (PCa) imaging has seen a relevant improvement through the clinical introduction of ^{68}Ga-PSMA-11. Yet, Gallium-68-labeled tracers have limitations due to relatively short half-life and low production capacities. As a result, Fluorine-18-labelled ligands such as PSMA-1007 and DCFPyL were developed. PSMA-1007 has an aditional advantage as it shows low urinary clearance, resulting in better positron-emission tomography/computed tomography (PET/CT)-imaging of the pelvis. We evaluated the diagnostic potential of PSMA-1007 in PCa patients with biochemical recurrence (BCR) in this study. **Subjects and Methods:** Seven patients (median age 72) with BCR (mean PSA 1.78 ng/mL) underwent PET/CT-scans 1h and 3h after injection of ^{18}F-PSMA-1007 (mean dose 247 MBq). Biodistribution in normal organs and tumor uptake, as well as lesion morphology (size) were examined. **Results:** All 7 patients tolerated PSMA-1007 well and no adverse events occurred. PSMA-1007 PET/CT detected local recurrence in 2 patients (PSA 1.9 and 3.6 mg/mL), lymph node (LN) metastasis in 2 patients (PSA 0.16 and 2.0 ng/mL), bone metastasis in 1 patient (PSA 3.8 ng/mL) and no PET-positive findings in 2 patients (PSA 0.4 and 0.5 ng/mL). Tumor uptake increased in all lesions from 1h p.i. (mean SUV_{max} 8.4) to 3h p.i. (mean SUV_{max} 14.1). Histological validation of one patient with LN-metastasis was available and confirmed true-positive findings. Additionally, response to succeeding radiotherapy gave further clinical confirmation. Distant metastasis was not confirmed but treated with androgen-deprivation therapy. Diagnosed LN-metastases were below radiological diagnostic criteria (size). Focal therapy would not have been an option with conventional staging alone. **Conclusion:** ^{18}F-PSMA-1007 PET/CT showed a high potential for localization diagnostics in patients with recurrent PCa in this pilot study. Low background signal in bladder and urethra were seen, resulting in a good delineation of local recurrence. This might present favorable in comparison to other ligands in the setting of BCR.

OP-704

The Importance Of Ga-68 PSMA PET CT In Detection Of Recurrence Metastasis Prostate Cancer Without Biochemical Recurrence

E. Akgun[1], O. E. Sahin[1], E. Demirci[2], B. Akovali[1], M. Ocak Demirci[3], A. Aygün[1], H. Pehlivan[1], E. Karayel[1], A. R. Kural[4], L. Kabasakal[1]; [1]İstanbul University Cerrahpasa Medical Faculty, İstanbul, TURKEY, [2]Sisli Etfal Educational Research Hospital, İstanbul, TURKEY, [3]İstanbul University Faculity of Pharmacy, İstanbul, TURKEY, [4]Acıbadem University Medical Faculty, İstanbul, TURKEY.

Positron emission tomography with Gallium 68 labeled urea based prostate specific membrane antigen inhibitor (Ga-68 PSMA PET/CT) is an important modality in staging prostate cancer. It is more sensitive than morphologic imaging modalities at restaging, even low Prostate Specific Antigen (PSA) level. **Material and Methods:** In our study, we included 28 patients with prostate cancer who underwent Ga-68 PSMA PET/CT in the context of increasing follow-up PSA values (n = 17) and suspected metastatic lesions (n = 11). All patients had definitive treatment either with radical prostatectomy (RP) or radiotherapy (RT). The average age was 64,22 years and median PSA level was 0,23 ng/mL (range: 0,001-1,98 ng/mL). Among them 17 patients had RP whose PSA level lower than 0,2 ng/ml (group 1) and 11 patients had definitive RT whose PSA level lower than 2.0 ng/ml (group 2). Gleason scores were 5 (n =1, %3,57), 6 (n =5, %17,85), 7 (n =8, %28,57), 8 (n =4, %14,28), 9 (n =5, %17,85) and unknown (n =5). Lesions with higher radionuclide uptake at PSMA PET/CT were considered pathologic and their follow up based on PSA levels, control PSMA PET/CT and/or other radiologic imaging modalities. **Results:** Overall positivity rate was 50% in PSMA PET scan. In group 1; 5 of 17 (29%) patients showed pathologic uptake at PSMA PET/CT. Among these patients 4 patients had increased PSA level during follow-up and in 2 patients progression was documented by follow PSMA PET/CT. Patients who had negative PSMA PET scan 6 of 12 patients (%35,29) had increased follow up PSA level and in1 patient progression of the disease documented by PSMA PET/CT. In-group 2; 9 of 11 (64%) patients showed pathologic uptake at PSMA PET/CT. Among them 7 patients (64%) had increased PSA level during follow-up and also 3 patients's follow PSMA PET/CT revealed progressive disease. **Conclusion:** Ga-68 PSMA PET/CT shows high positivity rates in patients with prostate cancer with low PSA levels and who had suspicion of recurrence even in lower PSA levels than so called biochemical recurrence.

OP-705

Can 68Ga - PSMA PET/CT predict seminal vesicle invasion for patients undergoing radical prostatectomy?

A. Agrawal, V. Rangarajan, G. Bakshi, G. Prakash, S. Menon, N. Purandare, S. Shah, A. Puranik, N. Sable; TATA Memorial Hospital, Mumbai, INDIA.

Aim: The primary aim of the study was to assess whether Ga PSMA PET/CT could predict stage T3b which is extension of the tumor into the seminal vesicles (SV). **Materials and Methods:** 35 patients with age range of 47-73, who were diagnosed to have prostate cancer by biopsy; underwent 68Ga-PSMA PET/CT prior to undergoing a radical prostatectomy (RP). 68Ga PSMA PET/CT was visually assessed for the primary tumor and uptakes were semiquantavely assessed by SUVmax. None of these patients demonstrated metastatic sites on PSMA PET/CT. All patients underwent RP, which was either open, laparoscopic or robotically done. Histopathology post-surgery assessed the primary tumor, extra prostatic invasion (EPE), seminal vesicle invasion and nodal disease. **Re-**

sults: On per patient basis, 8 out of 35 (23%) patients were positive for seminal vesicle invasion histopathologically. On lesion wise analysis 11 out of 16 SV were positive histopathologically. On PSMA PET/CT, 7 out of 8 patients were positive for SV invasion. On lesion based analysis, PSMA was positive in 8 out of 16 SV. On per patient basis, the sensitivity (SN), specificity (SP) positive predictive value (PPV) and negative predictive value (NPV) of PSMA was 87.5%, 100%, 100%, 96.43% respectively. On lesion based analysis the SN, SP, PPV and NPV were 66.67%, 100%, 100% and 50% respectively. **Conclusion:** 68Ga PSMA PET/CT can predict SV invasion with a very high PPV. Fusion of 68Ga - PSMA PET with MR in future may still enhance the prediction of SV invasion in patients of prostate cancer undergoing radical prostatectomy.

OP-706

Dual point 18F-Choline PET/CT in the evaluation of focal hypermetabolic prostate lesions. Acquisition timing protocol

A. Díaz[1], M. Soler[2], M. Cozar[2], G. Reyes[2], E. Riera[2], Á. Jaramillo[2], J. Ferrer-Rebolleda[2], J. R. García[2]; [1]CHUC (Complejo Hospitalario Universitario de Canarias), La Laguna, SPAIN, [2]CETIR-ERESA, Barcelona, SPAIN.

Objective: The stable or increased tracer uptake over time (accumulative pattern) vs its decrease (washout pattern) has been described as a method to differentiate between benign and malign lesions. However, there is no consensus on the 18F-Choline PET/CT acquisition timing protocol. The aim of this study was to determine the optimal dual-point protocol in the evaluation of focal hypermetabolic prostate lesions. **Material and Methods:** We prospectively studied, over the first 6 months of performing 18F-Choline PET/CT scans, 43 patients with prostate cancer. We identified hypermetabolic foci in 22 patients: 10 staging and 12 biochemical recurrence scans, being the last ones: 2 post-surgery, 4 post-brachytherapy and 6 post-radiotherapy. Patients were followed up clinically, radiologically and hystologically when it was possible. The PET/CT acquisition protocol was divided in 3 steps: early static image of the pelvis, immediately after injection (1 bed); whole-body 1 hour; whole-body 2 hours. We performed visual and semiquantitative analyses, calculating the median maximum standardized uptake value (SUVmax) and its increase or decrease, in percentage terms, between the steps (early/1hour and 1hour/2 hours), to determine whether tracer uptake remained stable/increased (accumulative pattern) or decreased (washout pattern). **Results:** We identified 28 hypermetabolic foci in the prostate glands, finding 2 lesions in 6 of the patients (5 staging and 1 post-radiotherapy recurrence scans). None of the patients showed ureteral/urinary bladder activity in the early static images of the pelvis, being the evaluation of the hypermetabolic foci between the three steps non discordant. 21 lesions had an accumulative pattern. The median SUVmax was: early: 3,04 / 1 hour: 3,45 / 2 hours: 4,0. The uptake increase was: early/1hour: +18'15% ; 1hour/2 hours: +11,26%. 7 lesions had a washout pattern. The median SUVmax was: early: 3,39 / 1 hour: 2,84 / 2 hours: 2,64. The uptake decrease was: early/1hour: -17,48% ; 1hour/2 hours: -7,05%. **Conclusions:** Dual point 18F-Choline PET/CT allows differentiation between accumulative pattern (malign) and washout pattern (benign). The optimal protocol to distinguish these two patterns is to acquire early (immediately post-injection) and 1 hour images.

OP-707

Reduction of 68Ga-PSMA renal uptake with mannitol infusion: preliminary results

G. Paganelli[1], E. Mezzenga[1], P. Caroli[1], A. Moretti[2], R. Galassi[2], M. Celli[1], L. Fantini[1], V. Di Iorio[1], A. Sarnelli[1], F. Matteucci[1]; [1]IRST IRCCS, Meldola, ITALY, [2]AUSL Romagna, Forlì, ITALY.

Purpose: Urea based -PSMA ligands labelled with 68Gallium or 177Lutethium are new tracers with great potential for a theranostic approach in prostate cancer (PCa). However, clinical studies have shown that the kidney is one of the target organs along with salivary and lacrimal glands. PSMA receptor is physiologically express in the proximal tubules and mannitol is diuretic of the proximal tubules. We are investigating the use of mannitol to reduce the renal uptake after the injection of 68Ga-PSMA and 177Lu-PSMA. **Subjects and Methods:** Kidney uptake (SUVmax) in 9 patients (pts) undergoing 68Ga-PSMA PET/CT in basal conditions (b-PET/CT) and after intravenous infusion of 500 ml of 10% mannitol (m- PET/CT), was calculated. Two different infusion schemes have been used: a) slow administration (40 minutes) after the injection of 68Ga-PSMA (A-infusion); b) fast-administration (50% of the total volume of mannitol in 15 minutes before injection of 68Ga-PSMA and 50% in the next 15 minutes) (B-infusion). **Results:** In A-infusion pts, an increase in the mean value of SUV_{max} of 11.9% and 7.4% for right kidney and left kidney respectively was found. In B-infusion pts, we observed a decrease in the mean SUV_{max} value in right kidney of 24.3% and in left kidney of 22.4%. **Conclusions:** our data show that mannitol may play a role in the reduction of kidneys uptake after 68Ga-PSMA injection. The mannitol administration should be rapid and before the radioactive tracer's injection. These data warrant dosimetric studies in patients treated with 177Lu-PSMA. Mannitol administration scheme can be further optimized.

Cardiovascular System: Atherosclerotic Plaque Imaging

OP-708

Non-invasive visualization of healing phase 2 after myocardial infarction (MI) using 68Ga-NOTA-anti-CD206-Nb: targeting mannose receptor (MR, CD206) on M2 macrophages

Z. Varasteh[1], A. Bartels[1], S. Mohanta[2], A. Steinsiek[3], Y. Li[2], M. Braeuer[1], N. López Armbruster[3], S. Nekolla[1], A. Habenicht[2], G. Raes[4], S. Hernot[4], H. Sager[3], M. Schwaiger[1]; [1]Klinikum rechts der Isar, München, GERMANY, [2]University Hospital of Ludwig-Maximilians-University, München, GERMANY, [3]Klinik für Herz und Kreislauferkrankungen, München, GERMANY, [4]Vrije Universiteit Brussel, Brussels, BELGIUM.

Introduction: Myocardial infarction (MI) is the most frequent cause of heart failure. The quality of intrinsic wound healing that occurs during the first 1-2 weeks after MI determines the fate of patients for years to come. Wound healing after cardiac ischemia is characterized by a first inflammatory phase in which the sterile wound recruits inflammatory leukocytes from the blood to the heart. Recruited monocytes differentiate into inflammatory macrophages that remove dead cells and extracellular matrix debris. The inflammatory phase is then succeeded by a reparative phase in which macrophages functionally shift from promoting inflammation to pursuing repair functions that ultimately result in a stable scar. Accordingly, an impaired resolution of inflammation consequently leads to adverse post-MI remodeling. Reparative macrophages can be distinguished from inflammatory macrophages by the surface marker mannose receptor (MR, CD206). Imaging the reparative phase of cardiac wound healing after MI is of great interest because it may early on reveal a delayed resolution of inflammation which in turn predicts adverse cardiac remodelling with development of post MI heart failure. Therefore, in this study we evaluated the feasibility of ^{68}Ga-NOTA-anti-CD206-Nb for imaging the MR expressed on alternatively activated, reparative macrophages in mice with experimental MI. **Methods**: Female C57BL/6 mice were subjected to myocardial infarction via permanent ligation of the left coronary artery. Non-operated (steady state) mice were used as controls. ^{68}Ga-NOTA-anti-CD206-Nb/PET acquisitions were taken 2, 6 and 14 days after MI. Consecutive [18]FDG/PET acquisition allowed the localization of the myocardium and the infarct zone. Upon PET/CT scans animals were euthanized and hearts were harvested. CD206-protein level on cardiac macrophages were quantified using flow cytometry. Immunofluorescent staining was executed with CD206 and CD68 targeting antibodies on cryosections. **Results**: PET/CT scans showed high ^{68}Ga-NOTA-anti-CD206-Nb myocardial uptake on day 6 after MI. Accordingly, flow cytometry experiments revealed that cardiac macrophages from day 6 after MI displayed significantly higher CD206 protein levels than macrophages from the steady state (1.236 ± 0.029 vs. 1 ± 0.018, mean fluorescent intensity (MFI)$\pm$SEM, p<0.01). Cardiac macrophages from day 2 after MI showed equal protein levels of CD206 than their counterparts from steady state (0.928 ± 0.023 vs. 1 ± 0.068 MFI/cell). Ex-vivo immunofluorescent staining on cardiac cryosections demonstrated the presence and co-localization of CD206- and CD68-positive cells (mainly macrophages), in accordance to the infected area. **Conclusion**: This exploratory study highlights the potential of ^{68}Ga-NOTA-anti-CD206-Nb to image reparative macrophages that are known to play a pivotal role in wound healing that follows acute MI.

OP-709

Non-invasive visualization of atherosclerotic plaques using ^{68}Ga-NOTA-anti-CD206-nanobody: targeting mannose receptor (MR, CD206) on M2 macrophages

Z. Varasteh[1], S. Mohanta[2], Y. Li[2], N. López Armbruster[3], M. Braeuer[1], S. Nekolla[1], A. Habenicht[2], H. Sager[3], G. Raes[4], S. Hernot[4], M. Schwaiger[1]; [1]Klinikum rechts der Isar, München, GERMANY, [2]University Hospital of Ludwig-Maximilians-University, München, GERMANY, [3]Klinik für Herz und Kreislauferkrankungen, München, GERMANY, [4]Vrije Universiteit Brussel, Brussels, BELGIUM.

Introduction: Atherosclerotic plaque phenotypes are classified based on the extent of macrophage infiltration into the lesions and certain plaque-resident macrophage subsets might be a sign for plaque vulnerability. Mannose receptor (MR, CD206) is expressed on alternatively activated (known as M2) macrophages. Recently, anti-CD206-Nanobodies (Nbs) were successfully used to specifically target tumor-associated macrophages as well as joint inflammation in rheumatoid arthritis. In the present study, we evaluated the feasibility of ^{68}Ga-NOTA-anti-CD206-Nb for imaging of CD206 expression on macrophages located in atherosclerotic plaques in apolipoprotein E-knockout (ApoE-KO) mouse model. **Methods:** NOTA-anti-CD206-Nb was labelled with [68]Ga. Binding selectivity and specificity of the radiotracer was checked in vitro. The biodistribution and in vivo specificity of the radiotracer was evaluated in control (C57BL/6) mice 1 h post injection (p.i.). For in vivo and ex vivo imaging studies, ^{68}Ga-NOTA-anti-CD206-Nb was injected into ApoE-KO and control mice and scanned 1 h p.i. For testing specificity of ^{68}Ga-NOTA-anti-CD206-Nb uptake in plaques, a group of ApoE-KO mice was co-injected with excess amount of non-labelled NOTA-anti-CD206-Nb. Upon imaging, the whole length aortas were harvested free from adipose tissue for autoradiography and Sudan-IV staining. Cryosections were prepared for immunofluorescent staining. **Results:** [68]Ga labelling provided a yield of greater than 99%. ^{68}Ga-NOTA-anti-CD206-Nb accumulated in vivo in CD206 expressing organs (i.e. liver and spleen) and showed only low residual blood signal (1.1 ± 0.1 %ID/g, 1 h p.i.). Binding specificity in receptor-positive organs was demonstrated by more than 1.5-fold reduced uptake of ^{68}Ga-NOTA-anti-CD206-Nb after co-injection of a blocking dose of non-labelled NOTA-anti-CD206-Nb. Multifocal signals could be detected in atherosclerotic plaques of ApoE-KO mice whereas no signal was detected in the aortas of control mice. ^{68}Ga-NOTA-anti-CD206-Nb uptake was detected in atherosclerotic plaques on autoradiography correlating well with Sudan-IV-positive areas. Calculated plaque-to-normal aortic tissue autoradiographic signal intensity was 7.7 ± 2.6 in aortas excised from ApoE-KO non-blocked mice. The Nb uptake in the plaques was associated with subendothelial accumulations of CD206- CD68-positive macrophages. **Conclusion:** ^{68}Ga-NOTA-anti-CD206-Nb accumulated in CD206 expressing organs and was associated with only low residual blood signal. In addition, ^{68}Ga-NOTA-anti-CD206-Nb uptake was detected in small dimension atherosclerotic plaques associated with the presence of CD206-positive macrophages suggesting that NOTA-anti-CD206-Nb represents a promising tracer for non-invasive detection of atherosclerotic plaques. Although the contribution of CD206-positive macrophages in the evolution and vulnerability of atherosclerotic plaques remains a matter of debate, it is clear that imaging of macrophage phenotypes is important in the context of plaque imaging and therapy.

OP-710

[68Ga]Pentixafor-PET/MRI for atherosclerotic plaque imaging

X. Li[1], D. Heber[2], X. Lu[3], X. Zhang[3], M. Mitterhauser[4], W. Wadsak[1], A. Haug[1], M. Hacker[1]; [1]Vienna General Hospital, Medical University of Vienna, Vienna, AUSTRIA, [2]Vienna General Hospital, Vienna, AUSTRIA, [3]Beijing Anzhen Hospital, Capital Medical University, Beijing, CHINA, [4]Ludwig Boltzmann Institute Applied Diagnostics, Vienna, AUSTRIA.

Background and Aim: Chemokines are expressed on cells of the atherosclerotic vessel wall and participate in the initial emigration of leukocytes to the sites of inflammation. The expression of chemokine receptor type 4 protein (CXCR4) was found to be co-localized with monocytes/macrophages. A novel PET tracer, Gallium-68 [68Ga]Pentixafor, a novel PET tracer with high affinity to CXCR4, has recently been introduced for the imaging of atherosclerosis. We sought to evaluate human atherosclerotic lesions using [68Ga]Pentixafor PET/MRI. **Methods:** 38 oncology patients underwent [68Ga]Pentixafor PET/MR imaging at baseline. Maximum standardized uptake values (SUV_{max}) were derived from hot lesions in seven arterial segments and target-to-blood ratios (TBR) were calculated. Spearman`s correlation coefficient and unpaired t test were performed for statistical comparison between uptake ratios and cardiovascular risk factors. The reproducibility of [68Ga]Pentixafor PET/MRI was assessed in seven patients with a PET/MRI follow-up exanimation 111±38 days after baseline. CXCR4 expression within different types of plaque lesions were estimated by Immunohistology. **Results:** 34 of 38 patients showed 611 foci with [68Ga]Pentixafor uptake that followed the contours of the large arteries. Both prevalence and mean TBR_{max} was highest in the descending aorta. There were significantly higher TBR values found in man (1.9±0.3) as compared to women (1.7±0.2; $P < 0.05$). Patients with mean $TBR_{max} > 1.7$ showed a significantly higher incidence of diabetes, hypertension hypercholesterolemia and history of cardiovascular disease than patients with mean $TBR_{max} \leq 1.7$. [68Ga]Pentixafor PET/MRI showed high reproducibility during baseline and follow-up examinations (r=0.6 for TBR_{max}, p<0.01) and there was no difference between the mean TBR_{max} values of plaque lesions ($TBR_{baseline}$ 1.8±0.3 vs $TBR_{follow-up}$ 1.8±0.3) (p=0.9). Co-locolization of CXCR4 protein expression were confirmed at fibrous plaque, atheromatous plaque and normal artery. **Conclusion:** [68Ga]Pentixafor could be detected and quantified by PET with high reproducibility. Patients with high arterial uptake showed significantly increased incidence of cardiovascular risk factors, suggesting a potential role of [68Ga]Pentixafor in the characterization of atherosclerosis. Key words: Chemokine receptor type 4, [68Ga]Pentixafor, Atherosclerosis, PET/MRI **Tables:** **Table 1.** Distribution of [68Ga]Pentixafor uptake in arterial lesions at baseline. **Table 2.** Lesional [68Ga]Pentixafor uptake at baseline compared to follow-up. P values were calculated using paired sample t-test to compare the TBR_{max} of baseline and follow-up scans.

OP-711

Imaging of LFA1 in Atherosclerotic Plaques Using a Novel SPECT Radiotracer

E. J. Meester[1], B. J. Krenning[1], M. R. Bernsen[1], G. Doeswijk[1], E. H. de Blois[1], J. P. Norenberg[2], M. de Jong[1], K. van der Heiden[1]; [1]Erasmus MC,

Rotterdam, NETHERLANDS, [2]University of New Mexico, Albuquerque, NM, UNITED STATES OF AMERICA.

Introduction: Atherosclerosis is a chronic disease of the arteries, characterised by a build-up of lipids and inflammatory cells in the vessel wall. Early detection of atherosclerosis and plaque monitoring following intervention remains a major challenge. Macrophages are attractive imaging targets for the detection of atherosclerosis, as they are involved in all phases of the disease. Lymphocyte Function associated-Antigen 1 (LFA1) is expressed on inflammatory cells including macrophages and is involved in cell migration into the vessel wall. The aim of this study was to non-invasively visualize atherosclerotic plaques through LFA1 targeted Single Photon Emission Computed Tomography/ Computed Tomography (SPECT/CT) imaging of macrophages using a novel tracer, In-111-DOTA-butylamino-Norbirt (DAN-BIRT), in a mouse model of atherosclerosis. **Methods:** Atherosclerotic mice (APOE $^{-/-}$) fed an atherogenic diet up to 20 weeks (n=10), were imaged by SPECT/CT 3 hours post injection of ^{111}In-DANBIRT (~200 pmole, ~50 MBq). *In vivo* imaging results were validated by *ex vivo* imaging and *ex vivo* autoradiography (ARG) of excised arteries. Oil Red O (ORO) staining of lipids was used to validate plaque presence in the arteries. Presence of macrophages and expression of LFA-1 in excised aortas was evaluated by immunohistochemical analysis of frozen tissue sections. Specific binding of the tracer to the target was assessed via *in vitro* ARG experiments. **Results:** *In vivo* SPECT/CT, *ex vivo* SPECT/CT, and *ex vivo* ARG showed tracer uptake inside aortic plaques. ORO staining confirmed fatty plaque build-up inside the aortic arch of all mice. *In vitro* ARG performed on mouse plaque sections confirmed specific binding, and immunohistochemistry showed macrophage and LFA1 co-localization inside plaques. **Conclusion:** Our results indicate ^{111}In-DANBIRT as a relevant tracer for non-invasive, in vivo visualization of atherosclerotic plaques and may provide a way to non-invasively monitor disease progression and therapeutic effects in patients with atherosclerosis.

OP-712

A Bradykinin Derivative Differentiates Vulnerable and Stable Atherosclerosis Plaques in Monkey

*Y. Xu[1], Z. Zhang[2], K. Lin[2], **Z. Liu[1]**; [1]Peking University, Beijing, CHINA, [2]BC Cancer Agency, Vancouver, BC, CANADA.*

Objective: Atherosclerosis is life-threatening disease that arises from the deposition of fatty plaques in the wall of arteries. Fatty plaques that can break off are called vulnerable plaques, which can be fatal as ruptured plaques would block arteries leading to acute myocardial infarction or ischemic stroke. To reduce mortality from such devastating cardiovascular events, it has been a long standing challenge to detect the presence of vulnerable plaques in high-risk but asymptomatic patients. In order to meet this challenge, recently we developed a ^{18}F-labeled bradykinin derivative (P05022) with high affinity to Bradykinin B1 receptor, which is not expressed in most tissues under normal conditions but up-regulated on vulnerable plaques. Here we report to

evaluate this PET imaging probe for identifying vulnerable atherosclerotic plaques in monkey models, and promising results have been achieved. **Method:** The receptor-binding domain of P05022 was derived from the B1R antagonist Lys-[Leu[8],desArg[9]] BK with Hyp[3] and Cha[5] substitutions to increase its in vivo stability. The binding affinity (K_i) was measured via competition binding assays using HEK293T:hB1R cell membranes. [18]F labeling was performed in NaOAc buffer (pH 4.1) at 95 °C for 10 min. Animal study was performed in rhesus monkey model, of that atherosclerosis was induced by high-fat diets over 5 years. PET image was collected at 60 min post injection. **Results:** P05022 binds B1R with high affinity (K_i = 2.3 nM), and [18F]P05022 could be prepared in high radiochemical yield (> 90 %) and purity (> 99 %). PET imaging showed the radioactivity was cleared rapidly from blood and normal tissues/organs, and was excreted mainly via the renal pathway. At 1 h p.i., atherosclerotic plaques were clearly visible in abdominal artery and femoral artery. The SUV (standard uptake value) of atherosclerotic plaque is up to 4.8, whereas the SUV of normal blood vessel, muscle and brain were 0.5, 0.4 and 0.1, respectively. **Conclusion:** P05022 selectively binds to B1R *in vivo* and generates high contrast images of vulnerable atherosclerotic plaque in monkey model. Our results suggest that P05022 is a promising PET tracer that can differentiate vulnerable atherosclerotic plaques from stable ones with significant specificity.

OP-713

Is FDG-PET/ CT a valuble diagnostic tool for verifying accelerated atherosclerosis secondary to diabetes mellitus in the aortic segments and large arteries?

G. G. Bural[1], D. A. Torigian[2], M. Houseni[3], M. K. Sozmen[1], A. Alavi[2]; [1]Izmir Katip Celebi University, Izmir, TURKEY, [2]Hospital of the University of Pennsylvania, Philadelphia, PA, UNITED STATES OF AMERICA, [3]Liver Institute, Cairo, EGYPT.

Aim: Atherosclerosis is a cardiovascular disease involving all arterial vascular beds marked by inflammation, plaque formation, and calcification. FDG-PET/CT has a well-established role for detection and quantification of atherosclerotic inflammatory disease using standardized uptake value (SUV) measurements. Detection of macroscopic arterial atherosclerotic calcification is also feasible via CT portion of PET/CT. Diabetes mellitus (DM) is a well-known risk factor which exacerbates the mechanisms underlying atherosclerosis. Thus, the inflammatory process and calcification in atherosclerosis is expected to be accelerated in subjects with DM compared to normal controls, and PET/CT could be a feasible tool evaluating both processes simultaneously. Our aim was to compare the inflammatory and macroscopic calcification processes of atherosclerosis in the aortic segments and large arteries of subjects with DM who are taking insulin compared to those of age-matched controls with no history of DM via FDG-PET/CT. **Methods:** 110 subjects who underwent FDG-PET/CT imaging were retrospectively studied. 55 were diabetics on insulin (61.5±10years old); 55 were age-matched controls (61.2±10 years old). Avarage SUVmax and SUVmean for four segments of aorta (ascending, arch, descending, abdomi-nal) and for common iliac arteries and common femoral arteries were measured and compared between subject groups. Presence or absence of macroscopic calcification on CT images for each arterial segment was also noted and compared between the two subject groups. Mann-Whitney-U test was used for continuous variables, and the chi-square test was used for categorical variables, p<0.05 was considered as statistically significant. **Results:** Avarage SUVmax and SUVmean were statistically significantly greater in subjects with DM on insulin compared to controls in all arterial segments (p<0.001). Presence of calcification on CT was more frequently encountered in six of the 8 segments in subjects with DM on insulin, and there was statistically significantly difference for the descending aorta (27/55 in DM subjects, and 14/55 in controls; p=0.01) and abdominal aorta (49/55 in DM subjects, and 35/55 in controls; p=0.0002). **Conclusion:** Our results show that inflammatory component of atherosclerosis as detected and quantified by FDG-PET/CT was more severe in all aortic segments and large arteries in subjects with insulin-dependent DM compared to those of controls. Presence of macroscopic calcification on CT was also detected to be more frequently encountered in the descending thoracic and abdominal aorta in subjects with DM. FDG-PET/CT is a valuable diagnostic tool for detecting and quantifying accelerated atherosclerotic inflammatory and calcific changes secondary to diabetes mellitus in the aortic segments and large arteries.

OP-714

Diagnosis of Deep Venous Thrombosis and Pulmonary Embolism Using ^{18}F-GP1 Positron Emission Tomography: An Exploratory Open-label Study

C. Kim[1], J. Lee[1], Y. Han[1], S. Chae[1], S. Oh[1], S. Lee[1], J. Oh[1], I. Oh[1], S. Chun[1], Y. Cho[1], T. Kwon[1], N. Koglin[2], M. Berndt[2], A. Stephens[2], D. Moon[1]; [1]Asan Medical Center, Seoul, KOREA, REPUBLIC OF, [2]Piramal Imaging, Berlin, GERMANY.

Purpose: [18F]GP1 is a new positron emission tomography (PET) tracer that binds specifically with a high affinity to activated glycoprotein IIb/IIIa receptors involved in platelet aggregation. The purpose of this study was to assess the detection rate of thromboembolic foci with [18F]GP1 PET. The safety, metabolism, biodistribution, and dosimetry of [18F]GP1 were also investigated. **Subjects & Methods:** Patients who had symptoms of acute deep vein thrombosis (DVT, n=7: 6 lower and 1 upper extremity) or pulmonary embolism (PE, n=8), and had DVT/PE focus/foci confirmed by computed tomography (CT) venography, ultrasonography or CT pulmonary angiography were enrolled. Dynamic whole-body PET images were acquired for up to 140 min after injection of 250 MBq of [18F]GP1. Analysis of DVT/PE foci included common/internal/external iliac, common/deep/superficial femoral, popliteal, tibial, peroneal, and gastrocnemius veins for DVT of the lower extremity; brachiocephalic, internal jugular, subclavian and basilic veins for DVT of the upper extremity; and main, lobar, and segmental pulmonary arteries for PE. For quantitative analysis, up to five of the largest lesions on standard images were selected. **Results:** [18F]GP1 administration and PET procedures were well tolerated in all patients. No

clinically relevant changes in safety parameters were observed. [^{18}F]GP1 PET showed initial uptake in the spleen, kidney, liver, and blood pool with rapid clearance. The determined effective radiation dose was in the range of other PET pharmaceuticals. The overall image quality was adequate for diagnosis in all patients. [^{18}F]GP1 PET identified thromboembolic foci in all 15 patients. Nine of them had both DVT and PE. Lesion based analysis revealed that [^{18}F]GP1 PET detected 43 of 49 DVT lesions (88%) in 12 patients and 112 of 185 PE lesions (61%) in 12 patients. Twelve patients had 31 distal DVT lesions on standard images, whereas [^{18}F]GP1 PET detected 46 distal DVTs in 13 patients. The number of additional distal DVT lesions identified only by [^{18}F]GP1 PET were 18 in 10 patients (1 popliteal and 17 calf veins). [^{18}F]GP1 PET also detected 3 additional PE lesions in 3 patients (1 lobar and 2 segmental arteries) which were not detected with standard imaging. The maximum standardized uptake values of reference thromboembolic foci were 5.61±2.32 for DVT and 4.39±1.92 for PE (mean ± SD). **Conclusions:** [^{18}F]GP1 may be a promising PET tracer for imaging acute DVT and PE with high sensitivity. Additionally, [^{18}F]GP1 PET may detect small previously undiagnosed thromboemboli, especially in distal veins of the lower extremity.

Cardiovascular System: Vascular Inflammation

E-PW001

The FDG-PET metabolic pattern, involving a low baseline-level and a subsequent increase, remains a landmark of less favorable outcome for the abdominal aortic aneurysms treated by endovascular prosthesis

P. Marie[1], D. Plisonnier[2], S. Bravetti[1], R. Coscas[3], M. Rouer[2], S. Haulon[4], D. Mandry[1], J. Alsac[5], S. Malikov[1], N. Settembre[1], Y. Gouëffic[6], O. Morel[7], V. Roch[1], E. Micard[1], Z. Lamiral[1], J. Michel[8], P. Rossignol[1]; [1]CHRU-Nancy, Vandoeuvre, FRANCE, [2]CHU-Rouen, Rouen, FRANCE, [3]Hôpital Ambroise Paré, Paris, FRANCE, [4]CHRU-Lille, Lille, FRANCE, [5]Hôpital HEGP, Paris, FRANCE, [6]CHU-Nantes, Nantes, FRANCE, [7]CHU-Besançon, Besançon, FRANCE, [8]INSERM Bichat, UMR 698, Paris, FRANCE.

Purpose & Introduction: The growing phases of the abdominal aortic aneurysm (AAA) treated medically are frequently associated with a ^{18}F-fluorodesoxyglucose Positron Emission Tomography (FDG-PET) imaging pattern involving: 1) a low baseline metabolism, reflecting a low parietal cellular density, and 2) a subsequent increase, presumably due to a growing inflammatory infiltrate (J Nucl Med. 2015;56:1030-1035). This prospective multicentric study was aimed at analyzing the metabolic FDG-PET patterns of the larger AAA treated by endovascular repair (EVAR). **Subjects & Methods:** Thirty-three patients referred for an EVAR of AAA (maximal diameter: 55±6 mm, total volume: 206±63 mL) underwent FDG-PET/CT before EVAR and 1- and 6-months thereafter, for monitoring the glycolytic metabolism of AAA (maximal standardized FDG uptake [SUVmax] averaged between axial-slices). Correlates of the 6-month decrease in AAA volume, defining sac shrinkage an indicator of successful repair, were analyzed. **Results:** Sac shrinkage was highly variable and could be stratified in three terciles with a first one where shrinkage was absent or very limited (0-29 mL) and a third one where it was marked (56-165 mL). Glycolytic metabolism was rather low at baseline in the 1st tercile (SUVmax: 1.73 ± 0.35) and thereafter clearly increased at 6-months (ΔSUVmax: 0.69 ± 0.65), it was much higher at baseline in the 3rd tercile (SUVmax: 2.63 ± 0.84, p=0.005 vs. 1st tercile) and stable over the 6-months (ΔSUVmax: -0.13 ± 0.52), whereas intermediate results were documented in the 2rd tercile (baseline SUVmax: 2.32 ± 0.42, ΔSUVmax: +0.53 ± 0.56). Finally, the amount of sac shrinkage was inversely related to the baseline glycolytic metabolism independently of the total AAA volume at baseline (p=0.007). **Conclusion:** The FDG-PET metabolic pattern, involving a low baseline-level and a subsequent increase, is also documented in the AAA treated by EVAR and exhibiting limited effects on sac volume and is therefore a definite landmark of less favorable outcome.

E-PW002

Prospective study comparing scintigraphy to radiolabeled leukocytes and 18F-FDG PET in patients suspected of vascular prosthesis infection

J. Pinaquy, Sr., M. Puges, X. Berard, j. Ruiz, F. Debordeaux, A. Desclaux, L. Stecken, S. Pereyre, L. Bordenave, C. Cazanave; CHU BORDEAUX, Bordeaux, FRANCE.

Introduction: Vascular prosthesis infections (VPI) are associated with high mortality rates. Diagnosis is often difficult, especially in latent infections. To improve the outcome of medical and surgical treatment, early and accurate diagnosis is essential and the actual diagnostic criteria are often insufficient. Our study aims to compare the performance of ^{18}F-fludeoxyglucose positron emission tomography (PET) and radiolabelled leukocyte scintigraphy (LS) for the diagnosis of IPV. **Material and Methods:** Prospective monocentric study including patients who received LS and PET for suspicion of VPI between April 2013 and June 2016 at the University Hospital of Bordeaux. Thoracic aortic prostheses were excluded. The diagnosis of VPI was assessed by Fitzgerald criteria at the end of follow-up. The accuracy of the two examinations was compared for each prosthesis. **Results:** Thirty-four patients were included, 14 had PVGI. Eighteen of the 93 prosthesis were infected. The sensitivity, specificity and accuracy were 88,9%, 92%, 91.4% and 89%, 85% and 86% respectively, for LS and PET. There was a significant difference (p = 0.022) between thoses two examinations. The agreement between observers was excellent for both examinations (kappa = 0.91). **Conclusion:** This study demonstrated an excellent performance of PET and scintigraphy with radiolabelled leukocytes for the diagnosis of IPV with excellent interobserver agreement. This study shows taht the scintigraphy have a better accuracy than [18]FDG-PET. Antibiotics do not seem to influence the performance of these two tests.

E-PW003

Comparison of 3 [18]FDG-PET visual interpretation scales for the diagnosis of vascular prosthesic infection

J. Pinaquy, Sr., M. Puges, C. Cazanave, J. Ruiz, F. Debordeaux, A. Desclaux, L. Stecken, S. Pereyre, L. Bordenave, X. Berard; CHU BORDEAUX, Bordeaux, FRANCE.

Introduction: Vascular prosthetic infections (VPI) are associated with high mortality rates. Diagnosis is often difficult, especially in latent infections. To improve the outcome of medical and surgical treatment, early and accurate diagnosis is essential and the actual diagnostic criteria are often insufficient. [18]FDG-PET/CT (PET), is a promising examination for the diagnosis of PVI. But criteria of interpretation remains unclear and none of the stuy use the sames parameters. We compared, from a prospective study interesting 93 prosthesis suspected to be infected, the performances of 3 visual scales. **Methods:** A monocentric prospective study including patients who underwent ^{18}F-FDG-PET/CT for suspicion of LPI between April 2013 and June 2016 at the University Hospital of Bordeaux. Thoracic aortic prostheses

were excluded. The diagnosis of VPI was assessed by Fitzgerald criteria at the end of follow-up. The performance of the 3 scales was compared for each prosthesis, 2 already published in the literature (Sah and Fukushi), the 3rd issue of our experience in PET assessment of vascular prosthesis infection. **Results:** Thirty-four patients were included, 14 had VPI. Eighteen of the 93 prostheses were infected. ROC curve analysis showes that our local scale had good performances (Sensitivity 89%, Specificity 85%, Accuracy 86%, ROC AUC = 0.87, 95% CI [0.786-0.955]), and was significantly more accurate than the scale of Fukuchi *et al.* (Sensitivity 67%, Specificity 85%, Accuracy 81%, ROC AUC = 0.76 [0.640-0.879], p = 0.04). Our local scale seems but was not significantly more accurate than the scale of Sah *et al.* (Sensitivity 83%, Specificity 72%, Accuracy 74%, ROC AUC = 0.777 [0.674-0.879], p = 0,069). For thrombosed grafts, our local scale was significantly more accurate than the scale of Sah *et al.*, but not significantly with the scale of Fukuchi *et al.* (ROC AUC = 0.963, CI 95% [0.913-1.000]; 0.778, CI 95% [0.609-0.946]) and 0.770, CI 95% [0.557-0.984], respectively, p = 0.00009 and 0.072). Inter-observer agreement was excellent for our scale, and good for the scales previously published by Sah *et al.* and Fukuchi *et al.*. **Conclusion:** This study seems to show a superiority of our visual scale visual in order to diagnose a vascular prosthesis infection especially in thrombosis prosthesis. A standardized interpretation would allow a better evaluation of the performance of [18]FDG-PET/CT.

E-PW004

18-FDG Pet-TC as tool to evaluate the efficacy of tocilizumab as a steroid-sparing agent for the treatment of Giant Cell Arteritis with Large-Vessel Involvement: a real-life single-centre case series

C. Olianti[1], G. Vitiello[2], C. Orsi Battaglini[2], N. Orsi Battaglini[3], R. Di Dato[3], S. Nicolosi[4], D. Cammelli[2]; [1]Nuclear Medicine Unit, Hospital-University Careggi, Florence, ITALY, [2]Experimental and Clinical Medicine Department, University of Florence, Florence, ITALY, [3]Nuclear Medicine Unit, University of Florence, Florence, ITALY, [4]Nuclear Medicine Unit, Hospital of Palermo, Palermo, ITALY.

Aim: To evaluate the usefulness of pre- and post-Tocilizumab (TCZ) therapy 18FDG-PET scan maximum standardized uptake value (max SUV; D TezuKa et al. JACC: cardiovascular imaging , vol 5, no. 42012 ; 422-429) for assessing disease remission in Giant cell arteritis (GCA) one of the two variants of Large-vessel vasculitis (LVV) which primarily affects medium and large sized vessels. To evaluate the efficacy and safety of TCZ as a steroid-sparing agent in patients with poor control of disease with Glucocorticoids (GC) or GC plus methotrexate (MTX). **Materials and Methods:** We retrospectively evaluated 12 GCA patients treated with TCZ (standard dose of 8 mg/kg/month) by pre- and post-therapy 18FDG-PET scan to assess activity and remission disease; post-therapy 18FDG-PET scan mean delay was 11.56 +/- 8.8 months (range 3 - 24 months) since the initiation of TCZ therapy. In addition to this, we evaluated clinical disease remission and reduction of mean GC dose. We evaluate max, mean and minimum SUV values in thoracic aorta, abdom-

inal aorta, subclavian, axillary, carotid, iliac and femoral arteries (Tool%ThresholdSUV on version V.4.5.3.40140 5.5.11 Gemini TF Philips Healthcare) and we choose maxSUV Thoracic Aorta for statistical analysis (IBM SPSS statistics 24). **Results:** maxSUV mean value has decreased from 2.05 +/- 0.64 to 1.78 +/- 0.45 (p = 0.005) after TCZ therapy; TCZ was effective in all patients, with a complete remission of the symptomatology. Mean GC dose was tapered from 26.63 +/- 13.42 mg/day to 3.3 +/- 3.1 mg/day (p < 0.0001). Overall, one half of the patients were able to discontinue GC therapy. Three patients discontinued MTX therapy without suspending GC therapy. Three patients experienced severe adverse reactions and had to stop TCZ therapy. **Conclusion:** maxSUV data could be considered a useful tool to evaluate the patients during TCZ therapy. Our maxSUV data are congruent with literature results and expressive of activity or remission of disease, as previously observed in other like-normal oncologic (1,82 +/- 0.27) and proved vasculitis (2,01 +/- 0.35) patient in our experience.

E-PW005

Tissue-to-background-ratio in major arterial vessels - comparison of 18F-FDG and 18F-fluoromethylcholine PET-CT

J. Jamsek, M. Grmek, S. Hawlina, L. Lezaic; Klinicni center Ljubljana, Ljubljana, SLOVENIA.

Background: 18F-fluoromethylcholine (18F-FCH) may be a new molecular marker of vascular inflammation. The aim of our pilot study was to directly compare metabolic activity of 18F-FDG and 18F-FCH in major arterial vessels. **Materials and Methods:** We retrospectively evaluated 18F-FDG (4 MBq/kg) and 18F-FCH (2,5 MBq/kg) PET-CT examinations of 13 male patients who had had examinations with both PET tracers within one week. TBRmean was measured in the ascending aorta (AscA), left and right common carotid arteries (LCC and RCC), thoracic aorta (TA), abdominal aorta (AA) and left and right common iliac arteries (LCI and RCI) and compared (t-test). **Results:** TBRmean for 18F-FDG and 18F-FCH in the AscA was 1.50 and 1.88 respectively (p = 0.046), in the LCC 1,57 and 1,65 (p = 0.644), in the RCC 1,45 and 1,45 (p = 0.987,), in the TA 1,46 and 2,13 (p = 0.010), in the AA 1,68 and 2,15 (p = 0.220), in the LCI 1,44 and 1,67 (p = 0.31) and in the RCI 1,64 and 1,51 (p = 0.698). **Conclusion:** 18F-FCH appears to yield comparable information on vessel wall metabolic activity in most anatomical vascular segments. For a more comprehensive analysis additional data as well as prospective studies comparing 18F-FCH and 18F-FDG are needed.

E-PW006

Correlation Between Vascular 18F-NaF Avidity and the Presence of Vascular Illness: A PET/CT Study

J. F. Alban[1], P. Lapa[1,2], M. Marques[1], A. Albuquerque[1], G. Costa[1,2], J. Pedroso de Lima[1,2,3]; [1]Centro Hospitalar e Universitário de Coimbra, Coimbra, PORTUGAL, [2]Faculdade de Medicina da Universidade de Coimbra, Coimbra, PORTUGAL, [3]Instituto das Ciências Nucleares Aplicadas à Saúde (ICNAS), Coimbra, PORTUGAL.

Purpose: Positron emission tomography/computed tomography (PET/CT) imaging using ^{18}F-sodium fluoride (^{18}F-NaF) has the potential to identify pathologically high-risk vascular microcalcification. This study aims to investigate a correlation between the presence of clinically detectable vascular disease and the vascular uptake of sodium fluoride labelled with Fluor-18 (^{18}F-NaF), and to establish a disease predictor value for maximum SUV (SUVmax). **Subjects and Methods:** We retrospectively reviewed 58 patients (22 male; 36 female), medium age 59.98 ± 40.3 years (17-82 years), submitted to PET/CT with ^{18}F-NaF between March 2011 and March 2017. The presence or absence of vascular uptake, SUVmax and localization of each uptake were recorded. The clinical charts of all patients were reviewed and two groups of patients were considered: 1) V0-no vascular uptake (n=8); 2) V1-with vascular uptake (n=50). The presence and location of clinically known vascular diseases were recorded. V1 group was then divided in 2 subgroups: 1) CV0-no clinically related vascular disease; 2) CV1-with clinically related vascular disease. According to the values of SUVmax, CV1 subgroup was subdivided into two new subgroups: 1) SM0 (SUVmax <2.15); 2) SM1 (SUVmax≥ 2.15). Statistical analysis applying Mann-Whitney test and ROC curves was performed. **Results:** For the 58 ^{18}F-NaF PET-CT studies, 129 vascular uptake locations were found (99 in CV0 and 30 in CV1 group) related to wall calcification, arterial occlusion, aneurysm, vasculitis and mitral disease. Mean SUVmax was significantly higher in the CV1 than in CV0 group (3.63 ± 5.64 vs 1.93 ± 0.64, p <0.001). For the V1 group, ROC analysis showed that SUVmax has a moderate predictive capacity for the occurrence of vascular disease (AUC=0.72, p<0.001) and the best cut-off point was 2.15 (specificity of 72% and sensitivity of 68%). For the SM1 group, when SUVmax≥2.15 and the presence of clinically known vascular disease were compared, a moderate concordance was found (k=0.316, p<0.001). **Conclusions:** There is a correlation between the presence of clinically detectable vascular disease and the vascular uptake of ^{18}F-NaF. A moderate concordance was found between having vascular uptake in ^{18}F-NaF PET/CT with SUVmax≥ 2.15 and having vascular disease at the same location.

E-PW007

Differences in semiquantitative 18F-FDG PET/CT findings of non-infectious and infectious inflammation

V. Mergen[1], I. Einspieler[1], M. Mustafa[1], H. Wendorff[2], K. Thürmel[3], M. Schwaiger[1]; [1]Department of Nuclear Medecine, Klinikum rechts der Isar TU Muenchen, Munich, GERMANY, [2]Clinic for Cardiovascular Surgery, Klinikum rechts der Isar TU Muenchen, Munich, GERMANY, [3]Department of Nephrology, Klinikum rechts der Isar TU Muenchen, Munich, GERMANY.

Objectives: The aim of the study was the evaluation and comparison of different semiquantitative parameters in patients with non-infectious large vessel vasculitis (LVV) and graft infection after aortic repair applying [^{18}F]fluorodeoxyglucose (FDG) positron emission tomography (PET)/computed tomography (CT). **Methods:** We included 17 patients with LVV and 28 patients with graft infection after aortic repair for retrospective

analysis. In the LVV group, the aorta and its major branches were analysed, whereas in patients with aortic graft infection only the graft area was evaluated. Maximum standardized uptake values (SUVmax) were obtained for all patients and different target-to-background ratios (TBRs) were calculated. 2 different background regions were defined and analysed (arterial and venous blood pool, respectively). The standard of reference for the diagnosis was defined as a combination of clinical follow-up, imaging (including PET/CT) and/or microbiological/histopathological results, if available. **Results:** SUVmax and TBRs were significantly higher in patients with graft infection compared to those with LVV (median SUVmax: 8.4 ± 3.9 vs. 4.2 ± 1.8; median TBR with arterial blood pool as background: 5.1 ± 2.2 vs. 2.1 ± 1.0; median TBR with venous blood pool as background: 5.3 ± 2.4 vs. 2.8 ± 1.1; p<0.0001). There was no substantial difference with respect to the blood pool activity in the 2 different groups. **Conclusion:** Our data show significant differences in patients with infectious and non-infectious inflammation with respect to different semiquantitative approaches. Thus, 18F-FDG-PET/CT may help to provide a better understanding of sterile and infectious inflammation.

E-PW008

18F-FDG PET/CT imaging for detection of aortic wall inflammation in patients with repaired coarctation of aorta

A. Georgakopoulos[1], N. Pianou[1], E. Oikonomou[2], A. S. Antonopoulos[2], I. Koutagiar[2], P. Kafouris[3,4], M. Metaxas[1], D. Tousoulis[2], S. Brili[2], C. Anagnostopoulos[1]; [1]Center for Experimental Surgery, Clinical and Translational Research, Biomedical Research Foundation, Academy of Athens, Athens, GREECE, [2]1st Department of Cardiology, 'Hippokration' Hospital, University of Athens Medical School, Athens, GREECE, [3]Center of Systems Biology, Biomedical Research Foundation of the Academy of Athens, Athens, GREECE, [4]Department of Informatics and Telecommunications, University of Athens, Athens, GREECE.

Purpose/Introduction: Patients with surgically repaired coarctation of aorta (RCoA) are at increased cardiovascular morbidity and mortality risk compared to general population. Endothelial dysfunction and impaired arterial elastic properties as well as relapse of arterial hypertension and pro-inflammatory stimulation could partly explain the increased cardiovascular disease risk of these patients. Positron emission tomography (PET) labeled with 18F-fluorodeoxyglucose (^{18}F-FDG) is currently considered the gold-standard imaging modality to non-invasively assess vascular inflammation in-vivo. The aim of this pilot study is to explore the role of ^{18}F-FDG PET/CT imaging in the assessment of aortic wall inflammation in RCoA subjects and the association of ^{18}F-FDG uptake with systemic inflammation and arterial elastic properties. **Subjects & Methods:** All participants underwent PET/CT imaging after intravenous administration of 140μCi/kg of ^{18}F-FDG and uptake period of around 120 minutes, preceded by at least 6 hours fasting. Target to background ratio (TBR) in the ascending, descending and abdominal aorta and their average (global aortic TBR) and coronary calcium burden

were calculated in 15 subjects with RCoA and compared with that of 15 age- and sex-matched subjects with prior history of lymphoma who needed ^{18}F-FDG-PET/CT imaging as part of their clinical follow-up and were disease free at the time of the investigation. RCoA patients also underwent assessment of central aortic mean blood pressure, arterial elastic properties and measurement of plasma levels of interleukin-6 (IL-6), transforming growth factor-beta (TGF-b) and macrophage colony-stimulating factor (MCSF) by enzyme-linked immunosorbent assay. **Results:** Global aortic ^{18}F-FDG uptake was significantly higher in RCoA compared to control subjects (1.95±0.08 vs. 1.76±0.03 respectively, p<0.05), mainly driven by differences in the descending aorta (2.04±0.07 vs. 1.76±0.05 respectively, p=0.003). The corresponding values in the ascending and abdominal aorta were 1.94±0.10 vs. 1.80±0.03 and 1.86±0.09 vs. 1.75±0.04, p=0.20 and p=0.25 respectively. There was no significant difference in coronary calcium burden between the two groups (p=0.19). In RCoA patients, aortic ^{18}F-FDG uptake was strongly correlated with plasma IL-6 levels (r=0.706, p<0.05), but not with TGF-b and MCSF levels. Moreover, patients with high aortic TBR (>median) had significantly higher central aortic mean pressure (105.2±1.9 vs. 91.6±5.3mmHg respectively, p<0.05), but not stiffness indices. **Conclusions:** Imaging of aorta by ^{18}F-FDG PET/CT detects aortic wall inflammation in adult RCoA patients. Aortic ^{18}F-FDG uptake values correlate with central hemodynamics and systemic low-grade inflammation.

E-PW009

Activity Assessment of Large Vessel Vasculitis with F18-FDG-PET(/CT)

N. Schramm[1], J. Ingenhoff[2], C. Dechant[3], F. Proft[3], H. Schulze-Koops[3], U. Hoffmann[2], A. Rominger[1], M. Czihal[2]; [1]Department of Nuclear Medicine, Ludwig-Maximilians University Hospital, Munich, GERMANY, [2]Division of Angiology, Department of Medicine IV, Ludwig-Maximilians University Hospital, Munich, GERMANY, [3]Rheumatology Unit, Department of Medicine IV, Ludwig-Maximilians University Hospital, Munich, GERMANY.

Purpose: To determine the role of 18F-Fluorodeoxyglucose (FDG)-PET/CT in activity assessment of large vessel vasculitis in patients under immunosuppressive therapy. **Materials and Methods:** 62 patients who underwent 80 PET(/CT) examinations (52 PET, 28 PET/CT) between 2004 and 2014 were included in this retrospective study. Clinical disease activity was investigated by medical history, clinical examination, laboratory tests (CRP, BSR), duplex ultrasound and/or CT/MRI and determined with established scoring systems (NIH-score, ITAS). Disease activity with PET was measured with the SUVmax of the aorta (SUVmaxAo), the SUVmax aorta/SUVmean liver ratio (ALR) and by applying a 4-point visual scale of the aortic (A) uptake vs. liver (L) uptake (3: A > L; 2: A = L; 1: A < L; 0: no uptake) and compared with the final clinical diagnosis (active vs. inactive). Correlations between clinical and PET parameters were calculated with Spearmans´s rank correlations analysis. ROC curve analysis and 4 field tables were used to determine diagnostic accuracy. Interobserver agreement of the visual PET reading was measured

with Cohen´s kappa. **Results:** Clinically, there was active disease (NIH score $\geq$ 2; ITAS-2010 6.5 $\pm$ 5.4) in 57 cases and inactive disease in 23 cases (NIH $\leq$ 1; ITAS-2010 1.1 $\pm$ 5.4). In comparison to CRP, BSR and ITAS there was a significant, but only mild to moderate correlation for SUVmaxAo (rho 0.25-0.48) and ALR (rho 0.36-0.63). With regard to the final clinical activity assessment the ROC statistics showed an area under the curve of 0.76 for SUVmaxAo and 0.9 for ALR. A cut-off of 2.6 for SUVmaxAo resulted in sensitivity of 71.4% and a specificity 73.9%; a cut-off of 1.3 for ALR resulted in a sensitivity of 84.2% and a specificity of 82.6%. Visual analysis (aortic uptake $\geq$ liver uptake: active disease) showed a sensitivity of 68.4% and a specificity of 91.3%. Interobserver reliability was excellent (kappa 0.93). **Conclusion:** Assessment of disease activity with FDG-PET(/CT) is specific and reliable if visual/semiquantitative ratios of the aortic wall to liver uptake are applied; however, sensitivity is limited.

Clinical translation of the caspase 3/7 specific PET radiotracer [^{18}F]ICMT-11 for measuring chemotherapy induced apoptosis in breast and lung cancer

S. R. Dubash[1], s. merchant[1], F. Mauri[1], k. kozlowski[1], A. Lim[1], N. Patel[1], J. Steel[1], k. Heinzmann[1], s. Azeem[2], S. Cleator[1], R. C. Coombes[1], E. O. Aboagye[1], L. Kenny[1]; [1]ImperialL College, London, UNITED KINGDOM, [2]Imanova Ltd., London, UNITED KINGDOM.

Background: Effective anticancer therapy requires induction of tumour cell death through apoptosis. [^{18}F]ICMT-11, an isatin sulphonamide and caspase-3/7 specific PET radiotracer, has been developed for PET imaging. [^{18}F]ICMT-11 demonstrated subnanomolar affinity to caspase-3 and has shown favourable dosimetry, safety and biodistribution in healthy volunteers. Here, we report results of [^{18}F]ICMT-11-PET for detection of chemotherapy-induced apoptosis in breast and lung cancer. **Materials and Methods:** [^{18}F]ICMT-11 was synthesized as previously described. Twenty patients diagnosed with breast cancer and 2 with lung cancer were recruited. All breast patients received neo-adjuvant chemotherapy (FEC: 5-fluorouracil, epirubicin, cyclophosphamide), and the lung patients received platinum-based chemotherapy; lesions measured 2cm or more. Dynamic-PET scans were acquired over 60 min pre-and post-chemotherapy, with arterial blood sampling to measure ^{18}F radioactivity concentration and metabolites in blood and plasma. Blood samples were taken to measure cytokeratin 18 (M65 and M30) using ELISA. Lung patients underwent DWI and DCE-MRI at baseline and post-chemotherapy. Regions of interest were drawn, to derive SUV_{60mean} and SUV_{60max}. All breast patients underwent a second breast biopsy within a few hours of the second PET to correlate apoptosis with PET in breast tissue. Caspase-3 expression, Ki-67 and H&E staining were performed

on all diagnostic and research biopsies. **Results:** Seventeen patients who had early (&#8804 48h post-chemotherapy) or late (>48h) scans were evaluable. The mean (range) dose injected was 330MBq (278-353MBq) pre-chemotherapy, and 335MBq (281-259MBq) post-chemotherapy. Three breast patients (scanned >48h) displayed histograms with higher voxel-intensities post-treatment indicating "apoptosis dominant" signature. Mean percentage shift to the right in all the 3 patients was 41% and all three patients had partial responses (PRs) on histopathology at surgery after 6 cycles of chemotherapy. One patient with an "apoptosis dominant" signature showed clear staining for caspase-3, together with increased blood cytokeratin-18-derived M30, and increase of M30:M65 ratio. All lung and breast patients were responders (PR or CR) at completion of chemotherapy treatment. Overall both "apoptosis dominant" and "necrosis dominant" [18F]ICMT-11 signatures were seen, however, no correlation with IHC, PET parameters or cytokeratin analyses could be demonstrated. **Conclusion:** These are the preliminary results of the first clinical study in lung and breast cancer using [18F]ICMT-11-PET. Further clinical evaluation will reveal if [18F]ICMT-11 can be used as a potential biomarker for chemotherapy induced apoptosis.

E-PW011

18F-RPS-544: An Imaging Agent Targeting CXCR4. Imaging and Biodistribution

A. Amor-Coarasa, J. M. Kelly, S. Ponnala, C. Williams, Jr., Y. Vedvyas, D. Kim, J. W. Babich; Weill Cornell Medical College, New York City, NY, UNITED STATES OF AMERICA.

Aim*:* The emerging importance of CXCR4 to cancer progression, prognosis and patient treatment makes it a potentially valuable target for imaging by positron emission tomography (PET). Only one 18F-fluorinated CXCR4 ligand has been reported to date, and although CXCR4-positive tumors were successfully delineated, the maximum uptake was 0.5 %ID/g. We sought to develop a 18F-labeled CXCR4 ligand with improved tumor uptake. **Methods***:* A 18F-fluoropyridyl analogue of AMD-3465 (IC_{50}=4nM) was prepared by nucleophilic aromatic substitution of a NO_2 group on a 6-nitropyridine moiety by no-carrier-added [18F]fluoride in DMSO at 150°C under basic conditions. 18F incorporation was determined using radioHPLC. Deprotection of the 18F-labeled intermediate was performed using 1 mL of neat TFA at 100°C. Preparative HPLC was used to purify the final product prior to formulation for injection. PET imaging was performed in nude mice bearing bilateral (CXCR4+ and CXCR4-) PC3 xenograft tumors. A full biodistribution was carried out at 1, 2 and 4h post injection (p.i.) to quantify tissue and tumor uptake. **Results:** 18F-RPS-544 showed preferential uptake in the CXCR4+ PC3 tumor, with a CXCR4+/CXCR4- tumor ratio of 3.3±1.3 at 1h p.i. and 2.3±0.5 at 2h p.i. Maximum uptake in the CXCR4+ tumor was **3.4±1.2 %ID/g** at 1h p.i., decreasing to 1.7±0.4 %ID/g at 2h p.i. and ≈1.5 %ID/g at 4h p.i. Tumor/blood ratios were determined to be 2.5±0.4 and 3.6±0.3 at 1 and 2h p.i., increasing to more than 9 at 4h p.i. Tumor/muscle ratio was greater than 5 at all time points. Tumor/lung ratios were greater than 1.5 at all time

points. Significant uptake was observed in the liver (24.7±3.6 %ID/g at 2h p.i.), kidneys (26.3±1.8 %ID/g at 1h p.i.), the small intestine (7.1±0.8 %ID/g at 1h p.i.) and the large intestine (9 %ID/g at 4h p.i.). The circulation half-life of 18F-RPS-544 was just over 36 minutes, with a blood concentration of 1.4±0.7 %ID/g at 1h p.i., 0.5±0.3 %ID/g at 2h p.i., and less than 0.2 %ID/g at 4h p.i. All other organs showed uptake of less than 1 %ID/g at all time points. **Conclusions:** A new imaging agent (18F-RPS-544) that targets CXCR4 was designed, synthesized, radiolabeled and evaluated in vivo. Specific targeting of CXCR4-positive tumors was demonstrated, and maximum tumor uptake reached **3.4±1.2 %ID/g**, a seven-fold improvement on existing 18F-fluorinated ligands reported to date. Clearance via the hepatobiliary pathway was observed, and good tumor/blood, tumor/muscle and tumor/lung ratios led to good contrast to background.

E-PW012

In vitro characterization of [18F]THK5351 binding to melanin-containing cells

T. Tago[1], J. Toyohara[1], R. Harada[2], S. Furumoto[2], N. Okamura[3], Y. Kudo[2], J. Takahashi-Fujigasaki[1], S. Murayama[1], K. Ishii[1]; [1]Tokyo Metropolitan Institute of Gerontology, Tokyo, JAPAN, [2]Tohoku University, Sendai, JAPAN, [3]Tohoku Medical and Pharmaceutical University, Sendai, JAPAN.

Introduction: Amyloid-β plaques and neurofibrillary tangles composed of hyperphosphorylated tau protein are the neuropathological hallmarks of Alzheimer's disease. In recent years, tau positron emission tomography (PET) imaging research has undergone marked progress. However, an issue regarding off-target binding, binding to regions without tau pathology (e.g., basal ganglia and melanin-containing cells (MCCs)), remains unresolved. Melanin, a polyanionic pigment derived from the amino acid L-tyrosine, has been suggested as the binding target in MCCs for [18F]THK5351 and other tau ligands. This study characterized the binding of [18F]THK5351 to MCCs and elucidated the relationship between structure and MCCs-binding activity. **Subjects and Methods:** We conducted [18F]THK5351 autoradiography (ARG) studies using postmortem sections of the human midbrain and pons. Binding assays of [18F]THK5351 to MCCs were performed using higher- and lower-melanin-containing B16F10 and B16 murine melanomas, respectively. Binding assays with synthetic melanin were also performed. Blocking activities of about two dozen compounds (e.g., tau ligands, amyloid ligands, monoamine oxidase B (MAO-B) inhibitors, and tyrosinase inhibitors) for [18F]THK5351 binding to B16F10 cells were investigated for the structure-inhibition relationship study. **Results:** ARG confirmed [18F]THK5351 binding to MCCs of the substantia nigra and locus coeruleus in midbrain and pontine sections, respectively. Binding of [18F]THK5351 to MCCs was saturable (Kd = 230 nM, Bmax = 160 fmol/mg protein for B16F10) and dependent on levels of melanin expression. Specific binding of [18F]THK5351 to synthetic melanin was also confirmed. The tyrosinase inhibitors did not block [18F]THK5351 binding, indicating a direct interaction of [18F]THK5351 with melanin. Tau ligands including amynopyridine groups such as AV-1451, PBB3,

and a lead compound of MK-6240 showed comparable levels of [18F]THK5351 binding inhibition to the self-blocking by THK5351 (>70% at 10 μM), whereas benzothiazoles such as PiB did not (about 10% blocking at 10 μM). Inhibition rates of MAO-B inhibitors and melanin ligand were low. These results indicate the aromatic rings of melanin-binding compounds are important for the pi-stacking interaction with melanin. In addition, a certain aminopyridine group seemed to enhance the melanin-binding affinity of compounds. **Conclusions:** Binding of [18F]THK5351 to MCCs was confirmed by in vitro ARG and binding assays. These results should facilitate accurate interpretation of PET images and the development of tau probes without off-target binding.

E-PW013
Alcohol-enhanced Cu-mediated radiofluorination

J. Zischler[1,2], N. Kolks[2], D. Modemann[1], B. D. Zlatopolskiy[2], B. Neumaier[1,2]; [1]Forschungszentrum Jülich GmbH, Institute of Neuroscience and Medicine, INM-5: Nuclear Chemistry, Jülich, GERMANY, [2]University Clinic Cologne, Institute of Radiochemistry and Experimental Molecular Imaging, Cologne, GERMANY.

Introduction: The potential of many 18F-labeled (hetero)aromatics for application in positron emission tomography remains underexplored because convenient procedures for their radiosynthesis are lacking. Consequently, simple methods to prepare radiofluorinated (hetero)arenes are highly sought after. Herein, we report the beneficial effect of primary and secondary alcohols on Cu-mediated 18F-labeling of (hetero)aryl pinacolyl boronates (ArBPin), boronic acids [ArB(OH)$_2$] and stannanes (ArSnMe$_3$). **Materials and Methods**: [18F]Fluoride was eluted from a QMA cartridge with a solution of Et$_4$NHCO$_3$ in the respective alcohol into a vial containing a solution of the corresponding precursor and Cu(py)$_4$(OTf)$_2$ in DMA. The reaction mixture was stirred at 110 °C for 5-20 min under air. The reaction was quenched with water before radio-HPLC analysis was carried out. Protected 6-[18F]fluorodopamine (6-[18F]FDA) and 6-[18F]fluoro-L-3,4-dihydroxyphenylalanine (6-[18F]FDOPA) were deprotected using 12 M HCl. The desired PET tracers were isolated by HPLC. **Results and Discussion**: We observed that the presence of traces of alcohols in the reaction mixture afforded radiofluorinated arenes in unexpectedly high radiochemical conversions (RCCs). Therefore, we studied the influence of different alcohols on Cu-mediated radiofluorination of PhBPin and PhB(OH)$_2$ precursors. Noteworthy, highest RCCs (up to 99%) were obtained using *n*-BuOH/DMA mixtures as reaction solvents. To demonstrate the versatility of the procedure, we radiolabeled a series of (hetero)arylboronic and (hetero)arylstannyl substrates. Different electron-rich, -deficient, and -neutral 18F-labeled arenes including unprotected indols, phenols and anilines were prepared in RCCs mainly exceeding or averaging 80%. The clinically relevant PET probes 6-[18F]FDA and 6-[18F]FDOPA were produced in radiochemical yields (RCYs) of 34 and 40%, respectively. **Conclusion**: The efficient application of alcohols as co-solvents for Cu-mediated 18F-fluorination was demonstrated. A procedure for rapid radiolabeling of a broad range of substrates such as (hetero)arylboronic acids, pinacolyl boronates, and trialkylstannanes under the same reaction conditions was developed. This procedure allows "late-stage" access to 18F-fluorinated indoles, phenols, and anilines from unprotected precursors and obviates time-consuming azeotropic drying. The preparation of clinical doses of two PET tracers, 6-[18F]FDA and 6-[18F]FDOPA, confirmed the practicality of the method. This work was supported by the DFG grant ZL 64/1-1.

Novel 18F-labeled triarylphosphonium derivatives for mitochondria imaging

S. Furumoto[1], T. Tominaga[1], R. Akita[1], A. Kazama[1], Y. Ishikawa[1], R. Iwata[1], K. Ishiwata[2]; [1]Tohoku University, Sendai, JAPAN, [2]Southern TOHOKU Research Institute for Neuroscience, Koriyama, JAPAN.

Purpose: A lipophilic cation like triarylphosphonium tends to accumulate in mitochondria depending on mitochondrial membrane potential (MMP). Mitochondria imaging is expected to be applied to visualization of mitochondria-rich tissues/organs, such as heart, tumor, and brown adipose tissue. The purpose of this study is to develop a novel 18F-labeled triarylphosphonium (18F-TAP) derivative for mitochondria imaging. We devised a new one-pot synthesis method for preparing the 18F-TAPs by using a 18F-labeled triarylphosphine as an intermediate. **Methods:** 18F-TAPs were prepared from 2-([18F]fluoroethoxyphenyl)diphenylphosphine through reaction with a derivative of benzyl or alkyl halide, and then isolated by semi-preparative HPLC. 2-([18F]fluoroethoxyphenyl)diphenylphosphine was prepared from the corresponding tosylate precursor under the conditions of general radiofluorination with 18F-KF/K222. Biodistribution study in mice (n = 4) was performed for evaluation of radiopharmacokinetics of the 18F-TAPs to choose a candidate as a cardiac imaging agent. Cellular uptake assays using H9c2 cells (rat embryonic cardiomyocytes) were carried out according to the dual tracer method with 3H-tetraphenylphosphonium (TPP), a gold standard tracer for MMP measurement *in vitro*, to clarify the relationship between the cellular uptakes of 18F-TAPs and MMP. Additionally, rat-PET scans were conducted to assess the performance of cardiac imaging. **Results:** Totally 12 derivatives of 18F-TAP were prepared with moderate RCYs (ca. 30-50%) according to the new method. Most of the derivatives showed high heart uptakes (> 6%ID/g) at 60 min post-injection. Cellular uptake of 18F-TAP-018, one of the derivatives, was well correlated with that of 3H-TPP and was inhibited with carbonyl cyanide m-chlorophenyl hydrazone (CCCP, an uncoupler) dose-dependently, suggesting that the TAP accumulates in mitochondria depending on MMP. 18F-TAP-031, another one of them, showed the highest heart uptake (15 %ID/g) and heart-to-liver uptake ratio (16.4) in mice. Then, rat heart was clearly visualized through PET scanning with 18F-TAP-031. **Conclusion:** We constructed a novel convenient method for preparing a 18F-labeled TAP, which could be applicable for automated radiosynthesis. Among the TAP derivatives prepared by the method, 18F-TAP-018 and/or -031 are potentially available for cardiac imaging, although further biological characterizations and experimental validations for measuring myocardial blood flow are necessary.

Synthesis and initial biological evaluation of [18F] fluorotryptophans ([18F]FTrps)

B. D. Zlatopolskiy[1,2,3], J. Zischler[2,1], H. Endepols[1], M. Guliyev[1], D. Schäfer[2], E. A. Urusova[1,2], B. Neumaier[1,2,3]; [1]University Clinic of Cologne, Cologne, GERMANY, [2]Forschungszentrum Jülich GmbH, Jülich, GERMANY, [3]Max Planck Institute of Metabolism Research, Cologne, GERMANY.

Objectives: Tryptophan and its metabolites are involved in different processes linked to biosynthesis of serotonin, melatonin and niacin. Consequently, PET-tracers targeting tryptophan metabolic pathways could be applied for imaging of related pathologies like neuropsychiatric diseases (e.g. depression) and tumors. The aim of this work was the development of efficient procedures for the preparation of [18F]FTrps and their initial biological evaluation. **Methods:** Boc-4,5- and -6-BpinTrp-OtBu (**1a-c**) were synthesized from the respective bromo derivatives using Miyaura borylation. Boc-7-BpinTrp-OtBu (**1d**) was prepared from Boc-Trp-OtBu via Ir-catalyzed 2,7-diborylation followed by the selective 7-deborylation. Bpin substrates were radiolabeled according to the protocol for alcohol-enhanced Cu-mediated [18F]fluorination. Radiofluorinated intermediates were deprotected using HCl in MeOH and purified by HPLC affording [18F]FTrps as ready-to-use solutions. The metabolic stability of radiolabeled tryptophans was determined in blood serum and liver microsomes. The cellular uptake of [18F]FTrps and [18F]FET was tested in MCF7, H69, PC-3 and LNCaP C4-2 tumor cells. A brain biodistribution of [18F]FTrps, [18F]FET and [18F]FDG in healthy rats was studied using µPET. **Results:** Precursors **1a-d** were synthesized in 40-65% yields. Intermediate Boc-x-[18F]FTrp-OtBu were prepared in >90% RCC. Radiochemically and chemically pure [18F]FTrps (ee >99%) were isolated in 42-54% RCY within 50 min. All four radiolabeled amino acids were stable in blood serum and liver microsomes for at least 90 min. Uptake of [18F]FTrps in all tumor cell lines was higher or similar to that of [18F]FET. Especially, uptake of 7-[18F]FTrp in MCF7 breast tumor cells with increased Trp metabolism was significantly higher than that of [18F]FET (3.71±0.01 and 4.93±0.12% of ID vs. 2.73±0.02 and 3.26±0.05% of ID after 1 and 2 h incubation, respectively). *In vivo* brain uptake of 4- and 6-[18F]FTrp was very low, while radioactivity strongly accumulated in the skull indicating fast defluorination of tracers *in vivo*. For 5-[18F]FTrp a uniform brain distribution and a moderate accumulation of radioactivity in the skull was observed. In contrast, 7-[18F]FTrp delineated serotoninergic regions of rat brain and the melatonin-synthesizing pineal gland. At the same time [18F]FET showed a uniform brain distribution and [18F]FDG accumulated in regions with high glucose metabolism. **Conclusions:** 7-[18F]FTrp is a promising PET-probe for imaging of Trp metabolism *in vivo*, which is easily accessible via alcohol enhanced Cu-mediated radiofluorination. **Research support:** This work was supported by the DFG grant ZL 65/1-1.

Positron emission tomography imaging of glioblastoma with a monosaccharide-based contrast agent

H. Hong[1], D. Yang[1], D. Chen[1], W. Lu[1], X. He[2]; [1]University of Michigan, Ann Arbor, MI, UNITED STATES OF AMERICA, [2]Hanjiang University, Wuhan, CHINA.

Purpose: Compared with most other biologically active molecules, saccharide is more biocompatible, chemically versatile, and cost-effective to synthesize. However, currently there is very limited report on using monosaccharides (other than 18F-fluoro-deoxyglucose [18F-FDG]) for cancer detection, despite the frequent clinical utilization of 18F-FDG for cancer diagnosis/staging. In this study, our goal is to fill in this research blank and develop a monosaccharide-based imaging agent for cancer detection, particularly for glioblastoma. **Methods:** A glucose derivative was screened out of a monosaccharide library, which demonstrated selective binding to U87MG glioblastoma cells. The screened candidate, 5-amino-4-benzyloxy-2-benzyloxymethyl-6-(4-methoxyphenoxy)-tetrahydro-2H-pyran-3-ol, abbreviated as ABMTP, was conjugated with p-SCN-Bn-NOTA or FITC for 64Cu labeling or fluorescence visualization, respectively. The cancer cell targeting efficiency was evaluated in U87MG cells with L929 fibroblasts as a control, by both flow cytometry and confocal fluorescence microscopy. PET imaging was conducted in nude mice bearing U87MG tumors with 64Cu-labeled glucosamine as control group. Organ distribution study by gamma counting was conducted to correlate with the PET findings, while auto radiography and histological analysis were also carried out to determine the potential binding target(s) for ABMTP. **Results:** NOTA or fluorescein was successfully conjugated onto ABMTP in a decent yield, analyzed by HPLC. Fluorescein-ABMTP demonstrated strong accumulation in U87MG cells and showed minimal interaction with L929 cells, while fluorescein-modified glucosamine did not get internalized into either of the two cell lines. An interesting observation is that fluorescein-ABMTP accumulates preferably in the cell nuclei rather than cytoplasm. 64Cu could be incorporated efficiently (> 50% decay corrected yield) into NOTA-ABMTP and the resulting 64Cu-NOTA-ABMTP (specific activity: ~ 4 MBq/µg) possessed a good stability in mouse serum. 64Cu-NOTA-ABMTP had a more potent and persistent uptake in U87MG tumors (9.1 ± 0.6 %ID/g at 2 h post-injection with tumor-to-muscle [T/M] ratio of 17.6 ± 3.6, n = 4) compared with those from 64Cu-NOTA-glucosamine (2.3 ± 0.3 %ID/g at 2 h p.i. with T/M ratio of 5.4 ± 1.1, n = 4). Finally, auto radiography and proteomics analysis of U87MG tumors suggested that proteins involved in epithelial-mesenchymal transition (EMT) process could account for the tumor cell internalization of ABMTP conjugates. **Conclusion:** We successfully developed a monosaccharide derivative as a PET contrast agent. This study can further encourage the development of other saccharide candidates to be used for cancer imaging. In addition, the cell nuclei accumulation preference can enable ABMTP to be used as a useful delivering agent for Auger electron emitting isotopes.

The Evolving Role of Succinate in Tumor Metabolism

P. GARRIGUE[1], A. Bodin-Hullin[2], A. Moyon[2], L. Balasse[1], S. Fernandez[1], W. Essamet[2], F. Dignat-George[1], K. Pacak[3], D. Taïeb[2], B. Guillet[1]; [1]Aix-

Marseille Université, Marseille, FRANCE, ²AP-HM, Marseille, FRANCE,
³NIH, Bethesda, MD, UNITED STATES OF AMERICA.

Beyond its role in carbohydrate metabolism as a tricarboxylic acid (TCA) cycle intermediate, succinate has a hormone-like function acting in various organs and tissues. In recent years, inherited and acquired mutations in the TCA cycle enzymes have been reported. Unlike tumors with isocitrate dehydrogenase mutations, pheochromocytomas and paragangliomas (PPGL) with succinate dehydrogenase (*SDH*) deficiency are characterized by an accumulation of highly elevated levels of succinate and high 18F-fluorodeoxyglucose ([18F]-FDG) avidity. This relationship is currently only partially explained. Therefore, we hypothesised that succinate could be the major connecting hub between *SDH*-mutated tumors and [18F]-FDG uptake profile. **Design:** To test whether succinate modifies the [18F]-FDG metabolic profile of tumors, we performed *in vitro* and *in vivo* (microPET/CT imaging and autoradiography) experiments in the presence of succinate, fumarate, and phosphate-buffered saline (PBS) in different cell models. GLUT1 immunohistochemistry was performed to assess whether [18F]-FDG uptake was correlated with GLUT1 staining. **Results:** Intratumoral injection of succinate significantly increased [18F]-FDG uptake at 24 hours on microPET/CT imaging and autoradiography. No effect of succinate was observed on cancer cells *in vitro,* but interestingly, we found that succinate caused increased [18F]-FDG uptake by Human Umbilical Vein Endothelial Cells (HUVEC) in a concentration-dependent manner. No significant effect was observed after intratumoral injection of fumarate or PBS. Succinate, fumarate, and PBS have no effect on cell proliferation, regardless of cell lineage. Intramuscular injection of succinate also significantly increases [18F]-FDG uptake by muscle when compared to either PBS or fumarate, highlighting the effect of succinate on connective tissues. GLUT1 expression quantification did not significantly differ between the study groups. **Conclusions**: The present study shows that succinate stimulates [18F]-FDG uptake by endothelial cells, a finding which partially explains the [18F]-FDG metabotype observed in tumors with SDH deficiency. Although this study is an [18F]-FDG based approach, it provides an impetus to better characterize the determinants of [18F]-FDG uptake in various tumors and their surrounding microenvironment with a special emphasis on the role of tumor specific oncometabolites.

E-PW018

The Preparation of Radiolabeled Aromatic Amino Acids via Cu-Mediated Radiofluorination of Ni-Complexes

A. S. Craig; Uniklinik Köln, Cologne, GERMANY.

Objectives: Recently developed methods for Cu-mediated radiofluorinations have paved the way for the fast and efficient preparation of [18F]-labeled aromatic amino acids (AAA), including the well-established 6-[18F]FDOPA and 6-[18F]FMT tracers and the lesser-known [18F]fluorophenylalanines ([18F]Phes) and [18F]fluorotryptophans ([18F]FTrps) for improved diagnostics of tumors and neurological disorders. However, insufficient stabili-

ty and/or poor accessibility of some substrates for radiolabeling hinder the broader application of these protocols for the routine preparation of PET probes. The aim of this project was to study the feasibility of a NiBPB auxiliary as easily-removable dual-protecting group functionality for the preparation of radiofluorinated AAA *via* Cu-mediated radiolabeling. **Methods:** NiBPB-Gly was alkylated with pinacolboronyl (BPin)-substituted benzyl halides or with 4-Bpin-substituted indole methide generated *in situ* from the respective methyl *N,N,N*-trimethylammonium salt (**1**). 2-and-4-BpinBnBr are commercially available, 2-BPin-5-MOMO-BnBr and 6-BPin-3,4-di-MOMO-BnBr were prepared by radical bromination of the corresponding toluenes. **1** was prepared from 4-BPin-indole using Mannich-type reaction followed by quaternization of the intermediate gramine. Radiolabeling was carried out according to the protocol for alcohol-enhanced Cu-mediated radiofluorination affording NiBPB-2 and 4-[18F]FPhe, MOM-protected NiBPB-6-[18F]FMT, di-MOM protected NiBPB-6-[18F]FDOPA, and NiBPB-4-[18F]FTrp complexes as follows: [18F]F⁻ was loaded onto a QMA-cartridge which was subsequently washed with acetone; [18F]F⁻ was eluted with Et_4NHCO_3 in *n*-BuOH to a solution of $Cu(py)_4(OTf)_2$ and the precursor in DMF. The reaction mixture was heated (110 °C) under air for 10 min, cooled, diluted with an excess of aqueous EtOH and analyzed by HPLC. To produce 4-[18F]FTrp NiBPB-4-BPinFTrp was [18F]-fluorinated under standard conditions and the mixture was concentrated *in vacuo*. Finally, the intermediate radiolabeled nickel complex was decomposed with 6M HCl/MeOH and the desired tracer was isolated by HPLC. **Results:** Diastereomerically pure boronated NiBPB-AA complexes were prepared in 50-85% yield. The respective Ni-complexes of radiolabeled AAA were synthesized in RCCs of 41-93% in >98% diastereomeric purity. 4-[18F]FTrp was obtained in unoptimized 25% RCY (non-decay corrected) within one hour in excellent radiochemical (>98%) and enantiomeric purity (ee >96%). **Conclusions:** Easily accessible boronated NiBPB-AAA complexes have been shown to be suitable substrates for alcohol-enhanced Cu-mediated radiofluorination. NiBPB represents an ideal framework for synthesis of precursors for radiofluorinated AAA. The practicality of the novel method was highlighted by the rapid preparation of 4-[18F]FTrp. **Research support:** This work was supported by the DFG grant ZL 65/1-1.

E-PW019

Development of a tumor-associated fetal protein derived peptide as a potential tool for the targeting of estrogen receptor positive breast cancer

S. M. Okarvi, I. AlJammaz; King Faisal Specialist Hospital and Research Center, Riyadh, SAUDI ARABIA.

Objectives: Several studies have shown that estrogen action can induce and promote breast cancer; therefore decreasing estrogen production or blocking its action with antiestrogens have been the main treatments for estradiol receptor ERα- positive tumors. There is an unmet clinical need for the development of effective breast cancer prevention radiopharmaceuticals possessing high therapeutic efficacy and low systemic

toxicity. Alpha-fetoprotein (AFP) is a safe naturally occurring human serum protein produced during pregnancy, which itself has anti-estrogenic and anti-breast cancer activity. Furthermore as nearly all breast cancers initially develop as estrogen receptor-positive cells and are estrogen-driven; AFP-derived peptides may be useful for preventive as well as for therapeutic management of human breast cancers. Therefore our interest was to prepare a synthetic peptide-derived from AFP and evaluate its potential for targeting breast cancer. **Methods:** An 8-amino acids AFP-derived peptide (amino acids 472-479) was generated using standard Fmoc-based solid-phase peptide synthesis and manually coupled to DOTA chelating agent to facilitate labeling with both ^{68}Ga and ^{177}Lu to formulate theranostic pairs. The tumor cell binding ability of the radiolabeled AFP peptide analog was determined on ER positive MCF7 and T47D breast cancer cell lines and in vivo tumor targeting study was conducted on nude mice bearing MCF7 breast tumor xenografts. **Results:** The structural identity and chemical purity of the synthetic AFP-derived peptide was confirmed by mass spectrometry and HPLC. The AFP peptide revealed efficient radiolabeling (>90%) with both diagnostic (^{68}Ga) and therapeutic (^{177}Lu) radionuclides. Additionally the radiopeptide exhibited a high binding affinity to ER positive MCF7 and T47D breast cancer cell lines with the binding affinities values were below 10 nM. In nude mice bearing human MCF7 tumor xenografts, ^{68}Ga/^{177}Lu-AFP displayed rapid clearance from the blood and uptake and retention in all the major organs was found to be low to moderate levels (below 4% ID/g). The accumulation in the ER positive MCF7 tumor was 2.14±0.68% ID/g at 1 h p.i., with good tumor to blood and muscle ratios of 2.6 and 7.1. The radiolabeled AFP-derived peptide was eliminated from the body mainly through the renal system. **Conclusion:** The promising findings of this initial study suggest that further development of this AFP-derived peptide appears to be indicated because of its compelling potential to be a novel agent for the management of breast cancer. If these preclinical findings translate successfully to human trials, many at-risk women would be able to prevent breast cancer with minimal, if any, morbidity.

Diagnostics of the sentinel lymphatic nodes in laryngeal and laryngopharyngeal cancer

I. Sinilkin, V.I. Chernov, E.L. Choynozonov, S.Yu. Chizhevskaya, A.Medvedeva, R.V. Zelchan, O.D.Bragina, V.S.Skur; Tomsk National Research Medical Center of the Russian Academy of Sciences, tomsk, RUSSIAN FEDERATION.

The aim of the study was to evaluate the diagnostic efficiency of ^{99m}Tc-Alotech and ^{99m}Tc-Technefyte radiopharmaceuticals (RFP) for detection of sentinel lymph nodes (SLN) in patients with laryngeal and laryngopharyngeal cancer. **Materials and Methods:** The study included 35 patients with laryngeal and laryngopharyngeal cancer. All patients were divided into 2 groups: 17 and 18 patients respectively. In the first group 99mTc-Alotech was introduced for sentinel lymph nodes visualization, the second group of patients was injected with ^{99m}Tc-Tehnefit. Injections of both RFPs were performed in 2-4 points (at a dose of 20 MBq in each injection) submucous along the perimeter of the tumor. Single-photon emission computed tomography (SPECT) of the neck area was performed on a gamma camera (E.CAM 180, Siemens) 3 and 18 hours after the administration of the radiocolloid. Evaluation of the results was carried out visually, as well as the calculation of the intensity of inclusion of RFP in SLP in comparison with the place of administration. Intraoperative detection of sentinel lymph nodes was carried out with the Gamma Finder II® gamma probe (USA) by carefully measuring of the level gamma radiation in the projection of lymphatic collectors. **Results:** In the first group of patients (n = 17), who were injected with 99mTc-Alotech, SLN were detected in all 17 patients in the number of 19 lymph nodes, while in the intraoperative radiometric study 20 SLN were identified. In the second group of patients (n = 18), who were injected with ^{99m}Tc-Tehnefit, scintigraphically succeeded in detecting 19 sentinel lymph nodes in 16 patients, and 23 SLN in 17 patients radiometrically. In the second group of patients (n = 18), who were injected with 99mTc-Tehnefyt, 19 SLN were scintigraphically detected in 16 patients and 23 SLN were revealed in 17 patients radiometrically. The intensity of ^{99m}Tc-Alotech inclusion in the SLN at the SPECT at 18 hours after the administration was 4-8% of the place of administration, with radiometry of 12-21%. When analyzing the data for ^{99m}Tc-Technefeet the values were 1.2-1.8% and 1.5-5%, respectively. **Conclusions:** Sensitivity of the sentinel lymph nodes detection using the ^{99m}Tc-Alotech radiopharmaceutical in patients with laryngeal and laryngopharyngeal cancer was 100%. While the sensitivity of detecting SLR using 99mTc-phytate was 94.4%. ^{99m}Tc-Alotech has a high level of fixation in SLN, which allows to improve the quality of visualization and to reduce the operation time.

E-PW021

PET/CT with 18F-FDG and 11C-Methionine for Assessment of Remission Status after Autologous Stem Cell Transplantation in Multiple Myeloma Patients

O. Mukhortova[1], I. Aslanidis[1], T. Katunina[1], A. Rumjantzev[1], A. Silchenkov[1], M. Solovev[2], L. Mendeleeva[2]; [1]Bakoulev Scientific Center for Cardiovascular Surgery, Moscow, RUSSIAN FEDERATION, [2]National Research Center for Hematology, Moscow, RUSSIAN FEDERATION.

Some recent data suggest that PET/CT is a promising method for diagnosis, staging, treatment assessment and estimation of prognosis for multiple myeloma (MM) patients. Effectiveness of different radiopharmaceuticals is still under discussion. **Purpose:** To compare the results of PET/CT with 18F-FDG (FDG) and 11C-Methionine (MET) in MM patients after autologous stem cell transplantation for remission status assessment. **Materials**

and Methods: All 18 patients had undergone one or two stem cell transplantation (SCT) - autologous or allogenic, at the time of PET/CT scanning had partial or complete remission status of MM: 8/18 had no M-protein secretion (NMS) and 10/18 had positive M-protein secretion (PMS). Whole-body PET/CT (including the skull) with low-dose CT scan was performed for all patients according to standard one day protocol: MET-scan in 20 min after injection (400 - 450 MBq) and 4 hours later FDG-scan in 90 min after injection (180 - 200 MBq). Visual assessment and SUVmax calculation for pathological foci were done. PET/CT results for both scans were compared with clinical and laboratory data. Analysis was performed on a patient and a lesion basis. The follow-up period was from 1 up to 9 months. **Results:** Overall 16 pathological foci were revealed on FDG scans and 28 foci on MET scans. The level of SUVmax in foci on FDG scans was lower than on MET scans: 2,7 - 3,9 vs 2,7 - 5,8. Diffuse marrow uptake of both tracers was detected in 2/18 patients. In NMS patients 3/8 had negative results in both scans (FDG and MET), 3/8 had positive results in both scans and 2/8 had positive MET but negative FDG results. In PMS patients 3/10 had negative results in both scans, 4/10 had positive results in both scans and 3/10 had positive MET but negative FDG results. In whole group the residual activity of MM was detected in 12/18 patients according to MET, whereas in 7/18 according to FDG, i.e. 5 patients were missed on FDG scans. Two patients had relapse during follow up - both with positive MET and FDG results, one from NMS and other from PMS group. **Conclusion:** According to primary results MET is a more accurate tracer than FDG for disease extension and residual activity detection in MM patients after SCT.

E-PW022

Cancer Lesions Detectability Limits in the SPECT Breast Imaging

E. Stiliaris[1], D. Maintas[2], D. Zarketan[1]; [1]National & Kapodistrian University of Athens, Athens, GREECE, [2]Institute of Isotopic Studies, Iatrikon Hospital, Athens, GREECE.

Aim: Breast imaging for early stage cancer diagnosis is still mainly relying on planar imaging techniques. Due to spatial resolution and sensitivity limitations in combination with absorption effects, whole-body PET and SPECT clinical scanners show a poor performance in tomographic level. In order to exercise in detail the detectability limits of small breast cancer lesions in a highly noisy background, a dedicated SPECT study with a breast phantom is presented here. The practical goal of the current analysis is to accurately define the tomographic limits of this method to successfully deliver accurate clinical tomographic images in a controllable signal-to-noise environment. **Materials and Methods**: A dedicated breast phantom in a cylindrical form (total volume 470 ml) has been constructed for this study. It can be filled with 99mTc water solution aiming to simulate in a proper way the noisy breast background and absorption effects normally observed in radiographic imaging detections. Four tubes and capillaries, arranged in axially asymmetric way and in various depths, can be filled with micrometric radiotracer volumes representing hot spot deposits. The breast phantom

is tomographically depicted with a small field and high sensitivity γ-Camera system consisting of a CsI pixelated scintillation crystal and a hexagonal parallel-hole collimator, all optimized for 99mTc detection. Scintillation light is read out by a Position Sensitive PhotoMultiplier Tube (PSPMT) and the position and energy information is reconstructed with an optimized Anger technique and recorded in an event-by-event mode. Entirely, 24 planar images in 15-degree steps are acquired; tomographic image reconstruction is carried out with different, well established methods, based on the Algebraic Reconstruction Technique (ART) and the Maximum Likelihood Expectation Maximization (MLEM) method. **Results**: Observed planar and tomographic images have been extensively analyzed for the various signal/background sets of the specific radioactivity. Results are presented analytically and the detection limits are given in terms of minimum detectable absolute tracer specific activity (µCi/ml). Effects of energy filtering by neglecting Compton events well below the 99mTc photo-peak are also presented. The measured efficiency of the system is finally compared to the expected ideal performance of the phantom-Camera system by means of GEANT4/GATE simulations. **Conclusion**: The current study presents in detail detectability limits for the SPECT breast imaging of clinical value with a dedicated phantom and a small field and high sensitivity γ-Camera system. Results will also serve as a feasibility study for the planned construction of a four-head γ-Camera device (Tetra-SPECT) dedicated to mammography.

E-PW023

Impact of Postoperative Diagnostic 131I Whole Body Scan with SPECT-CT on Staging, Risk Stratification and Radioiodine Therapy Planning in Low Risk Differentiated Thyroid Cancer

W. Teeyasoontranon, T. Kaewchur, S. Namwongprom, A. Klaipetch, M. Ekmahachai; Division of Nuclear Medicine, Department of Radiology, Faculty of Medicine, Chiang Mai University, Chiang mai, THAILAND.

Propose: To determine the use of postoperative diagnostic 131I whole body scan (131I DxWBS) with SPECT-CT on initial staging, risk stratification and 131I therapy planning in differentiated thyroid cancer (DTC) patients classified as low risk of recurrence based on clinical and histopathological data. **Subjects and Methods:** Seventy-one post-total thyroidectomy DTC patients (male = 7, female = 64, aged < 45 years = 34, aged ≥ 45 years = 37) classified as low risk stratification using ATA 2009 risk stratification system based on clinical and histopathology were enrolled into the study. Initial staging using AJCC/TNM staging system seventh edition was evaluated. 131I treatment planning to withhold or administer in low (1.1 GBq), medium (3.7 GBq) or high (5.5 GBq) activities of 131I was prescribed based on our institute protocol. Postoperative 131I DxWBS with SPECT-CT of neck and chest were performed at 4-6 weeks after total thyroidectomy. The additional SPECT-CT images of the specific regions based on equivocal lesions seen on planar imaging were obtained. Low activities of 131I (37 MBq) were used for 131I DxWBS. The 131I DxWBS with SPECT-CT were interpreted by two

blinded independent nuclear medicine physicians in a consensus reading. Staging, risk stratification and 131I treatment planning were re-evaluated based on additional 131I DxWBS with SPECT-CT findings. **Results:** Among 34 patients aged < 45 years, 131I DxWBS with SPECT-CT detected nodal metastases in 11 patients (32.3%, N1a = 6, N1b = 5), and distant metastasis in 1 patient (2.9%, bone and lung), which changed TNM staging in 1 patient (2.9%). Of 37 patients aged ≥ 45 years, nodal metastases were detected in 13 patients (35.1%, N1a = 7, N1b = 6) and distant metastases in 3 patients (8.1%, 2 bone, 1 lung), leading to change of TNM staging in 15 patients (40.5%). Risk stratification was changed from low risk to intermediate risk in 24 of 71 patients (33.8%) and to high risk in 4 of 71 patients (5.6%). RAI therapy planning was altered in 23 of 71 patients (32.4%). **Conclusion:** Our study results demonstrated that the postoperative 131I DxWBS with SPECT-CT altered the initial staging, risk stratification and 131I treatment planning based on the clinical and histopathology in low risk DTC patients. Nodal and distant metastases were detected leading to changing of the overall TNM staging in 22.5%, risk stratification in 39.4% and 131I treatment planning in 32.4% of our low risk DTC.

E-PW024

May 18F-Fluorocholine PET/CT Have A Role To Localize Parathyroid Adenoma In Patients With Negative 99mTc-MIBI?

F. Di Gregorio[1], M. Rensi[1], F. Vescini[2], D. Capobianco[1], F. Giacomuzzi[1], G. Ferretti[1], M. Povolato[1], O. Geatti[1]; [1]Department of Nuclear Medicine University Hospital, Udine, ITALY, [2]Department of Endocrinology University Hospital, Udine, ITALY.

Introduction: Primary hyperparathyroidism is not an uncommon disease and, being surgery the only curative treatment, a precise pre surgical localization of the adenoma is strongly recommended. Dual tracer 99mTc-sestamibi scintigraphy (MIBI), in particular when performed with SPECT/CT technique, is the most sensitive non-invasive imaging approach to localize hyperfunctioning parathyroid glands. Nevertheless its diagnostic accuracy decreases significantly in patients with very small parathyroid adenomas or multiple lesions. Aim of the study is to evaluate if 18F-Fluorocholine (FCH) PET/CT, that is commonly used in prostate cancer evaluation, can be helpful in localizing parathyroid adenoma not identified by MIBI planar and SPECT/CT. **Subjects and Methods:** 6 out of 20 consecutive patients (12 females and 8 males, age range 26-75 years) diagnosed with parathyroid adenoma on clinical and biochemical grounds, in whom MIBI scan with SPECT/CT acquisition did not detect the lesions, underwent a FCH-PET/CT acquisition (2 beds of 3 minutes) of the neck and mediastinal area after 60 minutes from i.v. injection of 350 MBq of FCH. Subsequently all the 6 patients underwent surgical neck exploration and a histo-pathological analysis was obtained. **Results:** histology confirmed parathyroid adenomas (volumes ranges 0,3 - 0,9 cm³) in all 6 patients and the localization of the lesions by FCH was correct in all the 5 patients in whom the study was positive (sensitivity: 83%). The patient with a false negative FCH had a very small lesion (0,3

cm³). **Conclusion:** our preliminary data suggest that FCH PET/CT could be an useful non invasive imaging modality to localize parathyroid adenomas in patients with a negative MIBI planar and SPECT/CT.

Sentinel node biopsy for bladder cancer using ICG-99mTc-nanocolloid

P. Meershoek[1,2], E. M. Wit[2], B. W. G. van Rhijn[2], G. H. KleinJan[1,2], E. Vegt[2], M. L. Donswijk[2], R. A. Valdés-Olmos[1], H. G. van der Poel[2], F. W. B. van Leeuwen[1]; [1]Leiden University Medical Center, Leiden, NETHERLANDS, [2]Netherlands Cancer Institute (NKI-AvL), Amsterdam, NETHERLANDS.

Introduction: Radical cystectomy with an extended pelvic lymph node dissection (ePLND) is considered the standard of care for non-metastatic muscle-invasive bladder cancer. The nodal status of the patient is of great importance for the prediction of disease recurrence and cancer-specific survival, hence the ePLND. The invasive nature of these procedures is, however, associated with complications like lymphocele and post-operative hematomas. We reasoned that specific targeting of the first tumor draining lymph nodes (sentinel nodes; SN) with a tracer that facilitates pre- and intraoperative guidance (indocyanine green (ICG)-99mTc-nanocolloid) could help provide a minimally invasive alternative for ePLND in bladder cancer. **Materials and Methods:** Ten patients scheduled for a radical cystectomy and ePLND with or without neo-adjuvant chemotherapy were included. Approximately eighteen hours before surgery the patients received four injections of ICG-99mTc-nanocolloid around the tumor (or random across the bladder in case of multiple tumors; under cystoscopic guidance). Preoperative SN mapping was done using planar lymphoscintigraphy (dynamic, 15 minutes, and 2h), followed by three-dimensional SPECT/CT (2h). Intraoperatively the SNs were identified using radio- and fluorescence guidance. The tumor find rate of the SN procedure an ePLND was assessed at pathology. **Results:** Cystoscopic deposition of the tracer using the endoscopic needle proved to be complex. In some patients there was leakage of the hybrid tracer into the urine, which resulted in radioactive contamination of the cystoscopy equipment. Four patients (40.0% of total) had non-visualization of SNs during preoperative SN mapping. In five of the six patients (83.3%) with SNs detected during preoperative imaging, SNs were removed successfully intraoperatively. In one patient (1/6; 16.7%) the SNs could not be removed using radio- and fluorescence guidance and could also not be found ex vivo. **Discussion/Conclusion:** Tracer administration proved to severely limit the success of performing SN biopsy in bladder cancer patients. SNs were removed successfully with radio- and fluorescence guidance in 83.3% (5/6) of the patients with SNs detected during preoperative SN mapping.

E-PW026

Correlation of hypoxia inducible transcription factor-1α, glucose transporter-1, carbonic anhydrase IX and FDG uptake in invasive ductal breast cancer

Y. Jeong, B. Choi, Y. Cho, S. Park, H. Oh, **S. Kang**; *Catholic University of Daegu School of Medicine, Daegu, KOREA, REPUBLIC OF.*

Background: Recently multiple biomarkers related to tumor hypoxic microenvironment have been discovered and offered as targets for cancer detection, treatment and monitoring, such as hypoxia-inducible transcription factors alpha (HIF-1α), glucose transporter-1 (GLUT1) and carbonic anhydrase IX (CA IX). We studied the immunohistochemical expression of HIF-1α, GLUT1 and CA IX in patients with invasive ductal breast cancer (IDC) and the correlation with SUVmax of the primary tumor (pSUVmax) as well as other biological parameters. Prognostic significance of pSUVmax, HIF-1α, GLUT1 and CA IX for the prediction of progression-free survival (PFS) was also assessed. **Materials and Methods:** One-hundred seventy four female patients with IDC who underwent pretreatment F-18 FDG PET/CT were enrolled. The pSUVmax was compared with clinicopathological parameters including ER, PR, HER2, axillary lymph node metastasis (LNM), stage, GLUT1, CA IX and HIF-1α. The prognostic value of pSUVmax, GLUT1, CA IX and HIF-1 α for PFS was assessed using the Kaplan-Meier method. **Results:** pSUVmax was significantly higher in patients with HIF-1α≥2, GLUT1≥5 and CA IX≥3 compared to patients with HIF-1α<2, GLUT1<5 and CA IX<3 (4.9±4.1 vs. 3.9±3.2, P=0.02; 6.1±4.2 vs. 3.5±3.0, P=0.003; 5.9±4.5 vs. 3.8±3.2, P=0.003). pSUVmax was also significantly higher in higher stage (P<0.001), ER-negative tumors (P<0.0001), PR-negative tumors (P=0.0009) and positive LNM (P=0.0283). pSUVmax was significantly higher in patients with progression compared to patients who were disease-free (6.4±3.5 vs. 4.1±3.6, P=0.0045). A receiver-operating characteristic curve demonstrated pSUVmax of 6.8, GLUT1 of 5 and CA IX of 3 to be the optimal cutoff for predicting PFS (sensitivity; 53.6%, specificity; 86.0%, P<0.0001; 60.9%, 72.2%, P=0.006; 56.5%, 80.8%, P=0.0054). Kaplan-Meier analysis identified pSUVmax ≥6.8 (P=0.0004), GLUT1≥5 (P=0.0005) and CA IX≥3 (P<0.0001) as predictors of recurrence. Cox proportional-hazards analysis showed that pSUVmax ≥6.8 (P=0.0338, relative risk 2.636), HIF-1α≥2 (P=0.0194, relative risk 0.331), GLUT1≥5 (P=0.0379, relative risk 3.139) and CA IX≥3 (P=0.0064, relative risk 3.829) significantly predicted recurrence. **Conclusions:** pSUVmax on pretreatment F-18 FDG PET/ CT reflect expression of HIF-1α, GLUT1 and CA IX and can be used as a good surrogate marker for the prediction of progression in patients with IDC. The amount of FDG uptake is determined by the presence of glucose metabolism and hypoxia in breast cancer cell.

E-PW027

Effect of stem cell transplantation on breast cancer-related lymphedema quantified by lymphoscintigraphy

J. A. Simonsen[1], S. Hvidsten[1], J. A. Sørensen[1,2], P. F. Høilund-Carlsen[1,2], N. M. Toyserkani[1,2]; [1]Odense University Hospital, Odense C, DENMARK, [2]University of Southern Denmark, Odense C, DENMARK.

Purpose/Introduction: Arm lymphedema is a debilitating complication of breast cancer treatment. Among different therapeutic strategies tested for, stem cell transplantation may hold promise. However, standardized methods for evaluation of the therapeutic effect have been lacking. We evaluated the effect of axillary stem cell transplantation by quantitative lymphoscintigraphy. Subjects & Methods: Ten women, aged 34-68 years, with unilateral upper limb breast cancer-related lymphedema were examined with bilateral lymphoscintigraphy before and a year after implantation of autologous fat-derived stem cells into the axilla of the lymphedema arm. From lymphoscintigraphy the mean transit time (MTT) of the tracer (Tc-99m HSA, 20 MBq in 0.1 mL) was calculated based on the uptake and retention of tracer in the upper limb; a high MTT corresponded to a slow transit and, hence, an accumulation of tracer in the soft tissue, while a fast transit was indicative of a well-functioning lymphatic drainage. The validity of this method has been reported elsewhere.1 Results: Clinically, patients experienced amelioration in terms of lower disability scores, reduced feeling of fullness and tightening, and less need for compression in five cases. Four patients suffered from recurrent skin infections before the intervention, none at one-year follow-up. Excess arm volume did not change significantly. Mean MTT±SD of the lymphedema arms was 63.4±25.4 min before the transplantation and 60.7±34.9 min after one year, p=0.65. Mean MTT of the healthy arms was 5.4±2.5 min and 7.9±2.8 min, respectively, p=0.002. Thus, these values did not suggest improved lymphatic drainage from the lymphedema arms, but a slightly delayed lymph flow in the healthy arms. Individual MTT(lymphedema arm)/MTT(healthy arm) ratios were lower after the intervention than before in all cases except one in that there was a decrease of the mean ratio from 16.2±13.7 to one of 7.9±3.4, p=0.004. One patient had a very high value before the intervention of 49.5. The mean before-ratio of the other nine patients was 12.5±8.4; hence, even a conservative judgement revealed a consistent change after one year in the balance between lymph flow in affected and healthy arm. Discussion/Conclusion: Following stem cell transplantation we observed a change in the balance of lymph flow in the two arms due to a decrease in lymph flow in the healthy arm, a finding indicating a certain systemic rather than exclusively local response to therapy. Consequently, therapeutic regimens against lymphedema should probably be monitored by methods, like our scintigraphic approach, considering the lymphatic drainage of both arms. **References:** J.A. Simonsen et al. Quantification of breast cancer-related lymphedema of the upper limbs. Abstract #2055 accepted for oral presentation at the SNMMI 2017 Annual Meeting.

Comparison of Magnetic Resonance Imaging (MRI) and 18F-NaF PET/CT for Detection of Spinal Bone Metastases in high-Risk Patients with Breast Carcinoma

E. Panagiotidis, A. Mistry, A. Farnworth, N. Seshadri, S. Vinjamuri; Royal Liverpool University Hospital, Liverpool, UNITED KINGDOM.

Introduction: The objective of this study was to evaluate the diagnostic accuracy of MRI and 18F-NaF PET/CT in detection of spinal metastases in patients with high-risk breast cancer. **Subjects and Methods:** Both patient and lesion-based analyses

have been performed on 66 consecutive patients (pts) (median age, 62.5 years; age range, 33-91 years) for restaging of newly diagnosed recurrent breast cancer with no previous bone metastases. All pts underwent Spinal MRI of Sagittal T1 and STIR sequences with localized axial T2 imaging along with 18F-NaF PET/CT before initiation of treatment, less than 20 days in between (median: 14 days) in our PET/CT department from September 2010 to March 2016. A nuclear medicine physician with PET/CT experience and a musculoskeletal radiologist evaluated the 18F-NaF PET/CT and MRI studies respectively. Follow-up exams with MRI, CT and 18F-NaF PET/CT as well as CT guided biopsy along with clinical follow up (22pts) (at least 12 months, median time: 19 months) were used as the standard of reference to evaluate 18F-NaF PET/CT and MRI studies. **Results:** On patient-based analysis, 26pts (39.4%) had bone metastases and 40pts (60.6%) was proven bone disease free during follow up. 18F-NaF PET/CT was positive in 40pts (60.6%) showing 97.5% sensitivity, 96.15% specificity, 97.5% positive predictive value (PPV) and 96.15% negative predictive value (NPV). Spinal MRI was positive in 39pts (59.1%) showing 95% sensitivity, 100% specificity, 100% positive predictive value (PPV) and 92.86% negative predictive value (NPV) with disease prevalence of 60.61%. There was concordance of both studies in 63pts (95.5%), MRI was superior in 2 pts (3%) and inferior in one (1.5%) pt. On lesion-based analysis, 18F-NaF PET/CT showed 175 lesions in total, 29 (16.5%) in cervical spine, 71 (40.5%) in thoracic spine, 48 (27.5%) in lumbar spine and 27 (15.5%) in sacrum. MRI revealed 190 lesions in total, 30 (15.8%) in cervical spine, 79 (41.6%) in thoracic spine, 51 (26.8%) in lumbar spine and 30 (15.8%) in sacrum. There was concordance of both studies in 52pts (78.8%), 18F-NaF PET/CT was superior in 4 pts (6%) and inferior in 10 (15.2%) pt on lesion based analysis. **Conclusion:** 18F-NaF PET/CT is a sensitive modality for detection of spine metastases caused by breast cancer. MRI shows a higher specificity but lower sensitivity than 18F-NaF PET/CT, with diagnostic advantage in detecting more spinal metastases, however of uncertain clinical benefit.

E-PW029

Evaluation of the Total Distribution Volume of 18FBPA in Normal Tissues of Healthy Volunteers by Non-Compartmental Kinetic Modeling

V. Romanov, K. Isohashi, E. Shimosegawa, T. Watabe, R. Beshr, J. Hatazawa; *Osaka University Graduate School of Medicine Department of Nuclear Medicine and Tracer Kinetics, Osaka, JAPAN.*

Background: Boron Neutron Capture Therapy (BNCT) with 4-borono-L-phenylalanine ([10]BPA) is a promising method of radiation therapy based on [10]B(n, α)[7]Li reaction inside tumor cells loaded with [10]B-labeled phenylalanine, causing cell destruction. Very short range of emerged ions (5-9 μm) reduces radiation dose to surrounding normal tissues, however the radiation dose depends on [10]B concentration in normal cells. Several studies (by Hanaoka K.; Watabe T.; Shimosegawa E.; Isohasi K.) have been performed in our laboratory to estimate [10]B concentration *in vivo* using 4-borono-2-[^{18}F]-fluoro-phenylalanine ([18]FBPA). The purpose of the current study was to evaluate total distribution

volume (Vt) of [18]FBPA in normal tissues of healthy volunteers by kinetic analysis. **Methods:** 6 healthy volunteers were injected with [18]FBPA (3-5 MBq/kg) and 7 PET-CT scans were performed subsequently. [18]FBPA radioactivity in whole blood and plasma was measured before, and 8 times after the injection within 50 minutes, using well counter. PET images have been processed by PMOD software (build 3.601). 11 volumetric regions of interest including brain, heart, right lung, spleen, liver, parotid salivary glands, esophagus, stomach, pancreas, intestines, bone marrow were drawn manually for each subject and analyzed with Logan plot (traditional and noise corrected) and Ichise multilinear (MA1 and MA2) models. Better model was defined by Akaike Information Criterion, Schwartz Criterion, Model Selection Criterion, and Coefficient of Determination. Also residual distribution was analyzed visually and using sum of squared residuals and standard deviation of the residuals. An equilibration time t* with maximal allowed error of 1% was set to 20 min for the Ichise MA2 model; to 20 and 28 min for the Ichise MA2 model; to 25 and 33 min for the Logan plot. Finally, Vt values were derived. **Results:** Ichise's MA2 model showed best fitting among all models. Vt values ranged from 0.94±0.14 ml/ccm in the pancreas to 0.15±0.01ml/ccm in the lung. **Conclusion:** Maximal Vt value of [18]FBPA did not exceed 1.09 ml/ccm, being much lower than values published for tumors as Vt itself (Grunewald C. et al., 2016) or those that could be derived from rate constants (J.C Chen et al. 2004; Imahori Y. et al., 1998), thereby reflecting lower K1/k2 ratio in normal tissues. Vt values obtained in this study could potentially be used for evaluation of [10]B concentration in normal tissues before BNCT with [10]BPA constant infusion protocol, however comparison of the estimated results with real boron concentration in normal tissues is needed.

Uncertainty in activity measurements using radionuclide calibrators due to source geometry effects

C. Saldarriaga Vargas[1], A. Carbutti[2], J. Dabin[1], K. Baete[3], L. Struelens[1]; [1]*Belgian Nuclear Research Centre (SCK-CEN), Mol, BELGIUM,* [2]*Politecnico di Torino, Turin, ITALY,* [3]*UZ Gasthuisberg, Leuven, BELGIUM.*

This study aimed to evaluate the uncertainty in activity measurements of clinical radioisotopes due to source geometry effects for different radionuclide calibrators (RC). Experiments were performed to assess the effect of container type and solution volume on the measurement accuracy. [18]F, ^{68}Ga, ^{99m}Tc, ^{111}In, ^{123}I, ^{131}I, [90]Y (chloride form) and [223]Ra were studied in various clinical containers, including 1-10ml plastic syringes and 2-25ml glass vials. A stock solution (SS) of each radionuclide was prepared in a standard 10ml Schott vial, and the reference activity concentrations were determined using a Fidelis Secondary Standard

RC. SS was then transferred to each container, and its reference activity was determined from the mass of the transferred solution and the SS activity concentration. The solution inside each sample was diluted with water to test for volume effects. Radioactivity was measured after preparation and following each dilution, both in the Fidelis and in RCs from Capintec and Comecer. Results showed that the activity read by all RCs is dependent on the container type. The RC response is usually higher (up to 40%) when the activity is measured in a syringe rather than in a clinical vial. This effect is stronger for radionuclides emitting low-energy photons: for ^{123}I and ^{111}In, field instruments can overestimate the activity in a syringe by 15-28%, whereas in a glass vial the activity can be underestimated by 5-15%. [18]F and ^{131}I were the radionuclides the least affected by the container type; however, measurements were not necessarily within ±5% of the reference value. In general, measurements were more accurate in the Schott vial than in clinical containers, probably because this container is more similar to the containers used by the manufacturers to calibrate the RCs (*e.g.* thin-walled glass ampoules). Regarding volume effects, the difference in activity reading between filling volumes, corresponding to about 20% and 80% of the nominal container size, was usually negligible or within 3-5% for most samples and RCs tested. Activity measurements using RCs can be strongly affected by the sample container. It is recommended to quantify these effects during acceptance/performance testing of RCs using the radiopharmaceuticals and containers most frequently used in clinical practice. If necessary, container-specific calibration (or correction) factors can be determined to improve the accuracy of radioactivity measurements in routine nuclear medicine. Finally, the accuracy of the activity reported by the suppliers of some radionuclides was also evaluated and is currently being analyzed.

Accuracy, Repeatability and Reproducibility of xSPECT Quant Sensitivity Calibrations using a NIST-traceable Point Source

*P. C. Holdgaard[1], H. C. Larsen[1], **N. A. Bebbington**[2]; [1]Lillebælt Hospital, Vejle, DENMARK, [2]Siemens Healthineers, Aarhus, DENMARK.*

Introduction: Before clinically interpreting quantitative values it is important to understand the error on the final measurement. A potential source of error in absolute SPECT quantification is the scanner sensitivity calibration. Sensitivity calibrations should be accurate, repeatable, reproducible, and should be representative of sensitivity across the detector. The aim was to assess accuracy, repeatability and reproducibility (over time and spatially across the detector) of sensitivity calibrations made according to the Siemens xSPECT Quant method using a NIST traceable Co-57 source. **Subjects and Methods:** Reproducibility with time: 35 sensitivity calibrations were made using a NIST-traceable Co-57 point source across two Siemens Symbia Intevo 6 systems (software version VB10), according to standard protocol, over a one-month period. Reproducibility across the detector: 11 sensitivity measurements were made across a 10cm distance in the z-direction in 1cm increments on one system.

Repeatability: 15 sensitivity calibrations were made in succession (with and without moving the source between measurements) on one system. Accuracy: a uniformity phantom filled with 51.3MBq Tc-99m-TcO$_4^-$ (as measured on a Capintec CRC15 dose calibrator) was scanned, and reconstructed with the quantitative OSCG algorithm, and the measured SUV compared to the known SUV of 1.00. **Results:** Accuracy: using a factor to correct for dose calibrator bias from prior cross-calibration between scanner and dose calibrator (as information on traceability of the dose calibrator to a primary standard was not available), the SUV of the Tc-99m uniformity phantom measured 1.00. Reproducibility with time: mean (±SD) sensitivity calibration factors (SCF) for detectors 1 and 2 were 88.5(±0.3%)cps/MBq and 88.0(±0.2%)cps/MBq for scanner 1, and 87.6(±0.2%)cps/MBq and 88.1(±0.3%)cps/MBq for scanner 2. Spatial reproducibility of SCF across the detector: Mean (±SD) SCF was 87.7(±0.4%)cps/MBq and 88.1(±0.5%)cps/MBq for detectors 1 and 2 respectively. Repeatability: without moving the source between measurements, standard deviations were 0.0% and 0.1% for detectors 1 and 2. When the source was moved between measurements, standard deviations were 0.1% and 0.2%. **Conclusions:** These findings demonstrate that xSPECT Quant sensitivity calibrations made using a NIST-traceable Co-57 point source give excellent accuracy, repeatability, and reproducibility with time and with location across the detectors. This method of sensitivity calibration thus contributes only an extremely small error to the final quantitative SPECT measurement, which is much less than is expected with manual Tc-99m calibration methods.

E-PW032

Determining the calibration factor of a SPECT/CT camera

L. Beels[1], *F. Lavent[1], I. Decostere[2], L. Tack[2], C. Van de Wiele[1], A. Maes[1]; [1]AZ Groeninge, Kortrijk, BELGIUM, [2]KU Leuven, Leuven, BELGIUM.*

Aim: Quantitative single-photon emission computed tomography (SPECT) has several important applications including monitoring tumor response after treatment and dose estimation for targeted radionuclide therapy treatment planning. The use of a calibration factor is required to obtain quantitative SPECT images. In this study, the calibration factor (CF) was determined for different acquisition and reconstruction protocols. **Materials and Methods:** A cylindrical phantom (height: 19.5 cm , diameter: 19.5 cm) was used for the SPECT/CT acquisitions (GE Discovery NM/CT 670). The phantom was filled with ^{99m}Tc, approximately 320 MBq for the first measurements and approximately 230 MBq for the second measurement that was performed to check the reproducibility of the calibration factor. The phantom was acquired four times using different acquisition parameters (change of acquisition time, matrix size, zoom factor) and the phantom was reconstructed using the GE Xeleris Volumetrix and GE Xeleris Volumetrix Evolution for Bone software. A volume of interest (VOI) (height: 15 cm, diameter: 17 cm) was drawn on the acquired images. Knowing the counts in the VOI, the volume of the VOI and the acquisition time, the count rate per unit volume was calculated. The CF was then determined by dividing the count rate per unit volume by the activity con-

centration decay corrected at the beginning of the acquisition. **Results:** The phantom reconstructed with the GE Xeleris Volumetrix resulted in a mean CF of 7.93 cpm/kBq (counts per minute per kilo Bequerel) for the 4 different acquisition protocols (CV: 0.04). Repeating this experiment resulted in a mean CF of 7.98 cpm/kBq (CV: 0.06) which only deviates 0.61% to the CF obtained during the first experiment. The phantom reconstructed with the GE Xeleris Volumetrix Evolution for Bone resulted in a mean CF of 40.51 cpm/kBq (counts per minute per kilo Bequerel) for the 4 different acquisition protocols (CV: 0.02). Repeating this experiment resulted in a mean CF of 41.29 cpm/kBq (CV: 0.02) which only deviates 1.93% to the CF obtained during the first experiment. **Conclusion:** The CF is not influenced by acquisition time, matrix size or zoom factor, but is highly influenced by the reconstruction parameters, more specifically resolution recovery (used in the GE Xeleris Volumetrix Evolution for Bone software). Therefore it is highly important when using a CF clinically to reconstruct the phantom data with the same reconstruction parameters as patient data.

Impact of the modelling of charge collection on the simulation of SPECT recordings from semiconductor CZT cameras

L. Imbert[1,2,3], J. Jurzcak[4], G. Karcher[1,2,5], P. MARIE[1,2,5]; [1]CHU Nancy, Vandoeuvre-lès-Nancy, FRANCE, [2]Plateforme d'Imagerie Expérimentale Nancyclotep, Nancy, FRANCE, [3]IADI, U947, Vandoeuvre-lès-Nancy, FRANCE, [4]Institut de Cancérologie de Lorraine, Vandoeuvre les Nancy, FRANCE, [5]Université de Lorraine, Faculté de Médecine, Nancy, FRANCE.

Introduction: The DSPECT CZT-camera (Spectrum Dynamics®) had already been simulated with the GATE platform, but without considering the partial collection of charges within the CZT detectors. This partial collection leads to a low energy tailing effect and is likely to deteriorate image quality. The aim of our study was to improve the Monte-Carlo simulation of the SPECT camera by the additional modeling the partial collection of charges of the CZT detectors. **Methods:** We used the Hecht equation[1], putting in relation the amount of collected charges with the depth of interaction of the γ photon within the CZT crystal, in order to model the response of the 9216 pixelated cristals of the DSPECT camera. The collimator geometry, the location and movement of each detector were modeled. A comparison was planned between the simulated and actually recorded data from punctual and spherical sources of ^{99m}Tc setting in the air or in a diffusing environment. In addition, heart images provided by the simulation with anatomic data from cardiac MRI, were compared with actually recorded SPECT images from the same patient. **Results:** The additional modeling of partial collection led to enhance the concordance between simulated and actually recorded data: 1) for the energy spectra from punctual and spherical sources, especially for experiments planed in diffusing environments, and 2) for the human SPECT images. For these latter, the myocardial contrast-to-noise ratios were 3.0 and 2.3 for simulation planed without and with the modeling of partial

collection respectively, as compared to 1.9 for the actual SPECT recording, and the corresponding sharpness indexes of myocardial walls (an index of spatial resolution) were 0.75 and 0.61 cm^{-1} respectively, as compared to 0.59 cm^{-1} for the actual SPECT recording. **Conclusion:** The additional modelling of the partial collection of charges leads to a great improvement in the simulation, through the Monte-Carlo GATE platform, of the SPECT recording from CZT-cameras, as evidenced by an enhanced agreement with actually recorded SPECT-data. *[1]Chen et al. Appl Radiat Isot 2008;66:1146-1150*

E-PW034

Simultaneous High-Sensitivity High-Resolution Molecular SPECT Imaging with Spinning Slit-Hole Collimator: A Monte Carlo Simulation Study

M. Ay[1,2], H. Mahani[3], G. Raisali[3], A. Kamali-Asl[4]; [1]Tehran University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF, [2]Research Center for Molecular and Cellular Imaging, Tehran University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF, [3]Radiation Application Research School, Nuclear Science and Technology Research Institute, Tehran, IRAN, ISLAMIC REPUBLIC OF, [4]Radiation Medicine Engineering Department, Shahid Beheshti University, Tehran, IRAN, ISLAMIC REPUBLIC OF.

Aim: Molecular SPECT imaging is always challenged by acquiring projection data with low statistics, leading to inferior image quality. In this study, we aim at comprehensively evaluating the performance of a novel collimation geometry, the slit-hole, using GATE Monte Carlo simulation. **Methods**: The slit-hole is a long narrow aperture embedded in tungsten body enabling high-sensitivity molecular SPECT. The collimator consists of a 0.6 mm knife-edge slit with 45 mm focal length. As the collimator measures planar projections, it spins at each regular SPECT angles, to ensure sufficient measurement of tomographic data. To assess the performance of this collimation system, a set of phantoms including a dedicated 5-point source and NEMA image quality (IQ) were simulated using the GATE Monte Carlo package. There were 16 spin angles as well as 16 SPECT angles. The planar projection data were also corrected for Compton scattering using a double-energy window method. The emission data acquired by the slit-hole were then reconstructed using an innovative 3D MLEM-based algorithm. Spatially varying system sensitivity was also molded in the reconstruction framework. **Results**: The slit-hole collimated scanner has a sensitivity of 335 cps/MBq at 30 mm distance, corrected for both scatter and background. The sensitivity of the proposed collimator shows a falling trend in field-of-view of the camera, weighted by distance from the aperture's center. A tomographic resolution of ~1.8 mm was gained at 30 mm radius-of-rotation. This spatial resolution is averaged for the 5 point sources distributed at different locations. Quantitative analyses demonstrated that 3 iterations of the developed algorithms leads to optimally reconstructed SPECT image by obtaining the highest signal-to-noise ratio. An 83% recovery of coefficient was observed for the largest rod in the NEMA IQ phantom. The slit-hole also gives rise to 4.8% image noise level for reconstruction of uniform part

the NEMA IQ phantom. **Conclusion**: The slit-hole collimation is a promising alternative to conventional pinhole and parallel-hole collimators for molecular imaging of small animals. The designed aperture shows a different resolution-sensitivity compromise by offering a high-sensitivity while keeping the spatial resolution at an acceptable level.

E-PW035

Accuracy of gamma camera efficiency determination using different experimental configurations

W. Zhao[1,2], P. L. Esquinas[1,2], X. Hou[2], C. F. Uribe[3], M. Gonzalez[4], J. Beauregard[5,6], Y. Dewaraja[7], A. Celler[2]; [1]Department of Physics and Astronomy, University of British Columbia, Vancouver, BC, CANADA, [2]Medical Imaging Research Group, Department of Radiology, University of British Columbia, Vancouver, BC, CANADA, [3]BC Cancer Agency, Vancouver, BC, CANADA, [4]Vancouver Coastal Health Authority, Vancouver, BC, CANADA, [5]Department of Radiology and Nuclear Medicine, Université Laval, Quebec City, QC, CANADA, [6]Department of Medical Imaging, CHU de Quebec – Université Laval, Quebec City, QC, CANADA, [7]Department of Radiology, University of Michigan Medical School, Ann Arbor, MI, UNITED STATES OF AMERICA.

Introduction: Accurate quantification of activity in nuclear medicine images, important for both research and clinical applications, requires determination of the camera calibration factor (CF). Although many methods have been proposed, there is still no consensus on which approach is the best. Our purpose was to compare these methods, to investigate the causes of their differences, and to propose a simple, practical and reliable camera calibration method which can be used in clinics for quantitation of radioactive isotopes for dosimetry in radionuclide therapies. **Subjects & Methods:** Experiments and Monte-Carlo simulations for three therapy isotopes (emitting beta particles and gammas: ^{177}Lu, ^{188}Re and ^{131}I) were performed. For each isotope, the data were acquired using three energy windows. The following experiments were performed: (1) planar scan of a point source in air, (2) tomographic scan of a source placed inside a cylinder filled with non-radioactive water (3) same configuration with radioactive water and (4) a cylinder filled with uniform activity. All tomographic scans were reconstructed using OSEM with CT-based attenuation and triple-energy-window (TEW) scatter corrections and CF were determined using total counts in the reconstructed image, while for planar scans, photopeak counts with (1A) and without TEW (1B) corrections were used. The experimental CFs were compared with those obtained from the corresponding simulations. **Results:** For all isotopes, the values of CF obtained from method (1A) agreed to within 5% with those from (3) and (4). However, planar scans without scatter correction (1B) produced higher CF values (20%-43%). The value of CF from method (2) CF exceeded those from other methods by 12%-15%. Analysis of simulations helped us to understand this discrepancy. It was due to inaccuracy of TEW scatter estimation which was enhanced by attenuation correction. This effect becomes less important when the source is distributed inside the phantom (configurations 3 and 4). **Conclusion:** In order to be practical,

the determination of camera CF must be simple and easy to perform. We have shown that planar acquisition of a point-like source provides the same CF as that obtained from quantitative tomographic reconstruction of an extended source, providing that self- and high-energy scatter and septal penetration are removed from planar data. But, using a tomographic scan of a source placed in non-radioactive background overestimates CF. Since activity in the patient body is usually distributed, similarly to that used in phantom (3) or (4), we conclude that method (1A) should be sufficient for CF determination.

E-PW036

Atlas-based pulmonary lobes segmentation implemented with MIM® for quantitative lung perfusion SPECT/CT analysis

C. P. L. Fulcheri[1], C. Tranfaglia[2], V. Reggioli[1], A. Chiappiniello[3], R. Tarducci[1], M. E. Dottorini[2]; [1]Medical Physics Department, Hospital Santa Maria della Misericordia, Perugia, ITALY, [2]Nuclear Medicine Department, Hospital Santa Maria della Misericordia, Perugia, ITALY, [3]Physics and Geology Department, University of Perugia, Perugia, ITALY.

Purpose: ^{99m}Tc-MAA functional lung scintigraphy is currently used in assessment of lobar function before surgical resection. Objective and accurate evaluation is possible by image quantification techniques. For years quantitation had been based on 2-d ROIs on anterior and posterior views. Nowadays, SPECT/CT provides 3-d information that can be used for a more accurate and clinically relevant definition of VOIs. To quantify radioactivity uptake in SPECT/CT, VOIs of lungs and lobes can be defined on the CT fused images. Manual or automated lung contouring is quite straightforward, whereas lobes segmentation can be time-consuming and challenging, especially when thin-slice or free-breathing/low-dose CT acquisition protocols are used. Our goal was to implement and evaluate an automated atlas-based segmentation of pulmonary lobes in order to make the contouring process fast, reliable and reproducible. **Subjects & Methods:** MIM software version 6.6.6 was used and a Single-Best Matched approach (SBM) was chosen. The reference anatomy atlas was constructed from 31 free-breathing thorax CT scans acquired with a Siemens SOMATOM Emotion 6. The contouring of right and left lungs, LM, LSD, LID, LIS, LSS was manually done by an expert clinician. The time needed for manually drawing of the ROIs was registered. Other 5 cases, with manually-created ROIs, were not included in the atlas, and were left for validation. The differences between manually and automated segmented ROIs were evaluated using the *F1-score* metric. The extra time to correct contours, if needed, was also registered. **Results:** The workflow included a rigid registration of a new patient to the template image in order to find the best atlas-matched subject and a successive deformable registration of the best matches to the patient (VoxAlign Deformation Engine). At the end of the image registration step, deformed atlas contours were transferred to the new image. Moreover, manual edit of the contours was possible. In all 5 cases the automatically generated contours needed to be slightly modified. To accurately contour all the lobes in 3 mm slice

width CT, the atlas-based segmentation and successive manual editing took 19±5 minutes per subject compared to 63±24 minutes required for completely manual segmentation. This represented a roughly 70% reduction in time. **Conclusion:** Preliminary results showed that the SBM contouring of pulmonary lobes implemented with MIM provided consistent time-saving over manual contouring. In the future the Multi-Atlas Segmentation approach will be studied as well as the effect of the contouring on the quantitative evaluation of perfusion SPECT/CT.

E-PW037
Development of a new phantom for DaTSCAN imaging

J. Taylor[1], R. Holmes[2], J. Fenner[3]; [1]Sheffield Teaching Hospitals, Sheffield, UNITED KINGDOM, [2]University Hospitals Bristol, Bristol, UNITED KINGDOM, [3]University of Sheffield, Sheffield, UNITED KINGDOM.

Introduction: Current commercially available phantoms for [123I]FP-CIT (DaTSCAN) imaging lack the flexibility to simulate realistic, patient-specific uptake patterns. Sub-resolution sandwich phantom (SSP) technology, using interleaved layers of attenuating material and printed radioactive ink patterns, has the potential to provide a practical, inexpensive solution. This proof of concept study aimed to: 1) Develop an example anatomical template, reflective of a clinical DaTSCAN patient 2) Assemble a full phantom, scan on a gamma camera and measure semi-quantification results. **Methods:** A DaTSCAN anatomical template was created through adaptation of the well-established MNI152 template. Pixel values within the caudate and putamen were set to a greyscale level that gave a printed count density ratio 8 times higher than that of the brain background (i.e. the phantom was designed with an 8 to 1 count density ratio, reflective of a healthy patient). The transaxial slices of the anatomical template were printed on to paper using a standard desktop inkjet printer (HP 8100), equipped with a black ink cartridge containing an ink and I123 Iodide mixture. Each printed paper sheet was stacked within interleaved layers of Perspex, cut to an oval shape, simulating attenuation effects within the skull. The fully assembled phantom was scanned on a Siemens Symbia T gamma camera, using LEHR collimators and standard clinical acquisition parameters. Scan time was adjusted in order to achieve > 1 million counts in the acquisition. Iterative reconstruction (8 iterations, 8 subsets) and semi-quantification was performed using MIM software, with the occipital lobe as a reference. **Results:** Phantom printing and assembly took approximately 1 hour to complete, utilising approximately 4ml of ink solution. Striatal binding ratios in the caudate and putamen were 2.91 and 2.77 respectively, on both left and right sides. Results are within the range seen for normal patients. **Conclusion:** This study demonstrated that SSP technology can be successfully adapted for DaTSCAN imaging, providing a controllable, flexible and inexpensive method for producing bespoke phantoms

E-PW038
SPECT-CT quantification of 131-Iodine - Reducing uncertainty with PSF modelling based reconstruction

L. Jenkins[1,2], A. Sohlberg[3,2]; [1]Queen Elizabeth Hospital Birmingham, Birmingham, UNITED KINGDOM, [2]Hermes Medical Solutions, Stockholm, SWEDEN, [3]Joint Authority for Päijät-Häme Social and Health Care, Lahti, FINLAND.

Introduction: Accuracy of 131-Iodine SPECT-CT quantification can be significantly improved with an iterative reconstruction algorithm incorporating full Collimator Detector Response (CDR) function modelling (septal penetration and septal scatter responses in addition to the geometric response). Furthermore, Monte-Carlo based patient scatter correction has potential to further improve quantification when compared to the Triple-Energy-Window (TEW) technique. The aim of this work was to assess whether improved SPECT-CT quantification of 131-Iodine could be achieved using full CDR function modelling and Monte-Carlo based patient scatter correction compared to current standard reconstruction using geometric response modelling and TEW scatter correction. CT based attenuation correction is used in both algorithms. **Methods:** A 34MBq 131-Iodine capsule was placed at the end of a 30cm long tube of diameter<1cm to be used within a Computed Tomography Dose Index (CTDI) body phantom. The tube was inserted into one of nine possible tubular holes (central, North/South/West/East 10mm from edge, NW, SW, SE, NW 53mm from edge) and imaged for 10s/projection and 120projections. Images were acquired at each of the nine locations for each imaging situation. The capsule was positioned at midpoint of phantom or externally (15cm away) by pushing tube through phantom and using it to suspend capsule in air. This enabled measurements to be performed in high and low attenuation/scatter conditions and allow similar contour orbits to be performed so that CDR and attenuation/scatter correction components could be assessed individually. A Siemens Symbia-T16 SPECT-CT system was used to acquire a range of images to include elliptical/26cm circular orbits with capsule in phantom and air at 0cm and 15cm z-axis offset from FOV centre. All data were reconstructed with Hybrid-Reconstruction and standard algorithms. Uptake was determined in a 5cm spherical VOI centred on the active capsule using HybridViewer (Hermes Medical Solutions). **Results:** There was substantially less variability in activity quantification using Hybrid-Reconstruction with full CDR modelling and Monte Carlo scatter correction than standard reconstruction algorithm; variability in air with capsule position was 2.9% v 42.3%. If quantification values are averaged over all imaging situations performed, then Hybrid-Reconstruction values vary from mean by -10.1% to 13.3% compared with standard reconstruction of -30.9% to 65.6%. **Conclusion:** Activity quantification was less affected by spatial location, nature of orbit and attenuation/scatter medium with Hybrid-Reconstruction than standard algorithm and images also were qualitatively superior. More accurate/reproducible SPECT-CT quantification of 131-Iodine can be achieved with commercially available reconstruction algorithms.

E-PW039
Impact of brain ventricle size on semi-quantitative index derived from 123-I-FP-CIT images using a novel 3D-striatum digital brain (3D-SDB)

H. Onishi[1], A. Furuta[1], K. Nakamoto[1], M. Takayama[1], H. Amijima[2];
[1]Program in Health and Welfare Sciences, Graduate School of Comprehensive Scientific Research, Prefectural University of Hiroshima, Mihara, Hiroshima, JAPAN, [2]Graduate School of Nursing, Hyogo University of Health Sciences, Kobe, Hyogo, JAPAN.

Aims: The quantitation of striatal dopamine transporter binding in Parkinson's disease is very important. A realistic digital brain phantom is needed to authenticate quantitative values derived from 123-I-FP-CIT SPECT images. The present study aimed to create a novel 3D-striatum digital brain (3D-SDB) phantom and assess the striatum binding ratio (SBR and SUR) to determine the effect of ventricular size 123-I-FP-CIT SPECT images. **Methods:** We constructed a 3-D striatum digital brain (3D-SDB) phantom comprising segments representing the striatum, ventricle, and brain parenchyma and skull bone using the Percentile method and other image-algorithm in T2-weighted MR images. The original image was converted to 128 × 128 matrixes to align the MR images with an added SPECT system for image resolution. A reference image was reconstructed based only on projection data sets generated from the original image. A process image was reconstructed with projection data sets generated from the original image with blurring, scatter, attenuation and static noise. Scatter, attenuation, and PSF were finally corrected in the process image. We derived the quantitative Southampton (DaTView; SBR) and anatomical normalization (DaTQUANT®; SUR) methods from reference and process images that were reconstructed to use OSEM (I = 2; S = 10). The effects of ventricle counts (0 - 200) and of a ventricle size that conformed to an Evans index between 0.2 - 0.5 (representing an enlarged ventricle) were evaluated to determine the accuracy of SBR and SUR obtained using the 3D-SDB phantom. **Results:** The practical value of a 3D-SDB phantom was assessed in a ^{123}I-FP-CIT SPECT clinical study. The true SBR values in the reference and process images were matched to calculate the SBR of the collected total striatum volume. The count and enlarged size of the ventricle caused a 5% - 10% difference in the SBR and SUR in the reference image. However, the SBR and SUR were overestimated by 18% and 8%, respectively, in the presence of ventricular counts in the process image. The effect of the enlarged ventricle (Evans index) was underestimated by 45% (SBR) and 20.5% (SUR) in the process image. **Conclusion:** This study constitutes the first step towards the accurate prediction of SBR and SUR using a 3D-SDB phantom that can conveniently reveal the basic features of ^{123}I-FP-CIT SPECT clinical images. The present findings suggested that an enlarged cerebral ventricle affects quantitative values derived from 123-I-FP-CIT SPECT images.

Background: Progressive metastatic radio-iodine refractory differentiated thyroid cancer (RR-DTC) is a rare condition in which a systemic therapeutic approach is needed. Recently, AIFA has approved the use of Lenvatinib, a new Tyrosine Kinase Inhibitors (TKIs), as an optional treatment for this group of patients. **Aim:** To assess the role of [18F]FDG PET/CT in monitoring treatment efficacy and predicting prognosis. **Patients and Methods:** From December 2014 to September 2016, 33 patients with RR-DTC were enrolled at the Department of Endocrinology of the University of Pisa (M/F=17/16; mean age: 65 years+/- 8,7; histologic type: 21 papillary thyroid carcinoma, 8 follicular thyroid carcinoma, 3 poorly differentiated thyroid carcinoma, 1 oxyphilic cells) and were selected for treatment with Lenvatinib. All patients underwent a baseline FDG PET/CT scan, then repeated after about 1, 2, 6 and 12 months during therapy. All scans were performed with a PET/CT Discovery 710 scanner (GE Healthcare, Milwaukee, USA) about sixty minutes after the injection of FDG (3.7 MBq/Kg). Metabolic response to therapy was assessed in each site of disease (thyroid bed, lymph node, lung, bone, and other sites) during the follow-up by qualitative evaluation, PET Response Criteria in Solid Tumors (PERCIST 1.0), maximal standardized uptake value (SUVmax), and by metabolic tumor volume (MTV) and total lesion glycolysis (TLG) as measures of metabolic tumor burden. **Results:** All patients had metastatic high metabolic involvement disease in more than two sites. During the follow-up, 21/33 patients presented progression metabolic disease by PERCIST, 14/21 after about 1 month since the onset of therapy. Fifteen out of 33 patients died during follow-up (median of survival 19.9 months), while 18/33 patients are still alive, though with a reduced dose of Lenvatinib because of adverse effects. In multivariate analysis, SUVmax MTV and TLG of the overall malignant process in the entire body at baseline were not significantly associated with overall survival. The majority of patients had decrease in total metabolic tumor burden during treatment. Early metabolic response (after 1 month) assessed by PERCIST criteria was significantly associated with mortality. Moreover, based on logistic regression there was a significant statistical evidence (likelihood-ratio test p <0.01) that survival depended on the persistence of TLG response (total and target ΔTLG %) at lymph node level after 6 months of treatment. **Conclusion:** FDG-PET/CT can be a useful tool to evaluate tumor response during TKIs therapy. The degree of metabolic response seems to have prognostic implications.

The role of [18F]FDG PET/CT in monitoring therapy with Lenvatinib in radio-iodine refractory differentiated thyroid cancer patients

E-PW041
Comparison of ^{18}F-fluoride PET/CT, ^{18}F-FDG PET/CT and ^{131}I radioiodine diagnostic scan in patients of differentiated thyroid carcinoma with skeletal metastases: evaluation of the role of ^{18}F-FDG PET/CT in bony metastatic disease from differentiated thyroid cancer

R. V. Parghane, S. Basu; Radiation Medicine Center (BARC), Mumbai, INDIA.

Purpose: The aim of this study was to compare the diagnostic values and accuracy of ^{18}F-fluoride PET/CT, ^{18}F-FDG PET/CT and ^{131}I radioiodine diagnostic scan for the detection of bone metastases and also to determine whether the ^{18}F-FDG PET/CT scan findings changed the outcome of medical and surgical management in differentiated thyroid cancer patients. **Subjects and Methods:** Retrospective evaluation of patients of differentiated thyroid cancer who underwent diagnostic studies between January 2016- March 2017 (n=510). A total of 54 patients (40 females and 14 males; age range 26-80 years, average 55 years) were included in this study, who had been known/suspected of having bone metastases (with complaints of bony pain, lower backache, fracture history and raised stimulated serum thyroglobulin level) and had undergone ^{18}F-fluoride PET/CT, ^{18}F-FDG PET/CT and ^{131}I radioiodine diagnostic scans after total thyroidectomy. The histopathology included follicular carcinomas (n=35), follicular variant of papillary carcinoma (n=8) and papillary carcinomas (n=11). Initially stimulated serum thyroglobulin levels ranged from 12 to 475 ng/ml with an average of 247 ng/ml and these patients were followed 1-6 years with an average of 3 years after the initial diagnosis. The correlative imaging and laboratory data for evaluating skeletal metastases were available such as CT or MRI findings, histopathological examination or clinical follow-up with serum thyroglobulin level. **Result:** In patient-based analysis, the sensitivity, specificity and diagnostic accuracy of ^{18}F-fluoride PET/CT were 60.98%, 46.15% and 57.4%, respectively, those of ^{18}F-FDG PET/CT were 91.30%, 87.50% and 90.7% and those of ^{131}I radioiodine diagnostic scan were 88.37%, 90.91% and 88.8% respectively for detection bone metastases. In 11 patients (20.3%), other metastatic organ involvement was detected by ^{18}F-FDG PET/CT and also in 26 patients (48.1%) additional bony sites were demonstrated by ^{18}F-FDG PET/CT. Following ^{18}F-FDG PET/CT showing positive bony lesions, 10 patients (18.5%) underwent stabilization of fracture sites, 7 patients (12.9%) underwent EBRT and 3 patients (5.5%) underwent surgical excision of bony metastatic lesions. **Conclusion:** ^{18}F-FDG-PET/CT and ^{131}I radioiodine diagnostic scan showed high diagnostic performance in detecting bone metastases from DTC as compared to ^{18}F-fluoride PET/CT. Our results showed ^{18}F-FDG-PET/CT can detect extra metastatic bony sites, other metastatic organs, which can lead to modification of the management and improvement in the quality of life of DTC patients.

Incremental value of ultrasonography in incidental focal thyroid uptake at 18F-FDG PET-CT.

W. Yao; *College of Medicine, National Cheng Kung University, TAINAN, TAIWAN.*

Purpose: We aim to evaluate the incremental value of ultrasonography for further assessment of incidental focal thyroid uptake detected with 18F-FDG PET-CT in a PET center. **Subjects and Methods:** Between Jan 2015 and March 2017, a total of 2491 studies with whole-body 18F-FDG PET-CT were performed, including 558 studies for cancer screening. Focal thyroid uptake lesions were identified if they were greater than background thyroid tissue. Further evaluation of incidental focal thyroid uptake with ultrasonography was performed and assessed with TI-RADS lexicon. Patients with suspicious malignancy (category 4 or higher) went for fine needle aspiration or biopsy. **Results:** Of the 2491 PET/CT studies, 156 (5.94%) incidental focal thyroid uptake were identified in 146 patients, 117 patients for cancer work-up and 29 for cancer screening. Forty-seven nodules in 40 patients with suspicious malignancy on ultrasonography went for histological diagnosis. Seven nodules with inadequate sampling were excluded. Nigh teen were histologically diagnosed as malignant (16 papillary carcinoma, 2 anaplastic carcinoma, 1 papillary carcinoma with follicular variant) and 21 were benign lesions (19 benign follicular nodule, 2 Hashimoto's thyroiditis). In 40 histologically diagnosed nodules, malignant tumors were higher in SUVmax (11.5±8.8 vs. 4.7±2.2, p=0.0012). With cut-off value of SUVmax 6.2, the sensitivity and specificity for detecting malignancy were 73.7% and 81.0 %, respectively. **Conclusion:** Ultrasonography may increase specificity of incidental focal thyroid uptake in 18F-FDG PET-CT, avoid unnecessary invasive procedures, and provide proper recommendation for further management.

131I-SPECT/CT in the diagnosis and characterization of metastatic lesions in patients with differentiated thyroid carcinoma (DTC) in chronic follow-up

A. Spanu, I. Gelo, L. Mele, B. Piras, S. Nuvoli, G. Madeddu; University of Sassari, SASSARI, ITALY.

Aim: We further investigated 131-SPECT/CT usefulness in DTC current diagnosis and therapeutic post-operative protocol reassessment. **Methods:** Among a large DTC series, we retrospectively selected 79 patients (32 males and 47 females) with ascertained metastatic lesions during chronic follow-up. At surgery, 35 patients were at high risk (H), 28 at low risk (L), 16 at very low risk (VL). 131I-WBS (diagnostic in 72 and post-therapeutic in 7) was performed using a dual head gamma camera equipped with high-energy, parallel-hole collimators and with low dose x-ray tube. WBS was always followed by SPECT/CT over neck/chest and other suspect regions, for total 160 exams. **Results:** 131I-WBS detected 90 metastatic foci in 39/79 patients, 53 in and 37 outside the neck, while SPECT/CT identified 198 metastatic foci in the 79 patients, including all foci positive at WBS, 124 in and 74 outside the neck. Thus, SPECT/CT identified 108 neoplastic foci occult at WBS in 51 patients, 71 lesions being neck lymph node metastases and 37 metastases outside the neck (8 lung, 6 mediastinum, 20 bone, 3 pelvis). WBS was completely negative in 38/51 patients, 15 H, 13 L, 10 VL, two of L and10 VL being T1aN0M0 with undetermined Tg levels in 6 cases, <2.5 ng/ml in 5 and between 2.5 and 5 ng/ml in 6; moreover, 21/38 patients had single lymph node metastases and 7/21 cases (6 VL, 1L) were T1aN0M0 with undetermined Tg levels in 6 and < 2.5 ng/ml in the remaining one. Moreover, SPECT/CT also characterized as malignant 53 lesions in the neck in 19 patients and 15 outside the neck in 7 patients classified as benign or unclear at WBS; 4/19 patients (2L,2VL) with lymph node metastases

were T1N0M0 with undetermined Tg in 3 cases and between 2.5and 5 ng/ml in the remaining one. Two of these 4 cases (2VL) and further 2/19 cases (1L, 1VL) had single metastases. Five of 7 patients with 15 lesions outside the neck had Tg levels >10 ng/ml. Globally, SPECT/CT correctly changed WBS classification and patient management in 72.1% of cases. **Conclusion:** 131I. SPECT/CT proved reliable diagnostic tool in DTC follow-up localizing and characterizing iodine fixing metastatic lesions with better performance than WBS and more correct patient classification and management. SPECT/CT usefulness is more significant in patients with inconclusive WBS and Tg levels undetermined or very low, mainly in VL cases with T1aN0M0 and even more with single metastases.

Diagnostic Utility of Molecular and Imaging Biomarkers in Cytologically Indeterminate Thyroid Nodules: a Systematic Review and Meta-Analysis

E. J. de Koster[1], *L. F. de Geus-Oei*[2], *O. M. Dekkers*[2], *I. van Engen-van Grunsven*[1], *J. F. Hamming*[2], *E. P. M. van der Kleij-Corssmit*[2], *H. Morreau*[2], *A. Schepers*[2], *J. W. A. Smit*[1], *W. J. G. Oyen*[3], *D. Vriens*[2]; [1]Radboud university medical center, Nijmegen, NETHERLANDS, [2]Leiden university medical center, Leiden, NETHERLANDS, [3]Institute of Cancer Research, London, UNITED KINGDOM.

Introduction: Indeterminate thyroid cytology (Bethesda III and IV) corresponds to follicular-patterned benign and malignant lesions, which are particularly difficult to differentiate on cytology alone. As approximately 25% of these nodules harbor malignancy, diagnostic hemithyroidectomy is still standard-of-care. However, additional preoperative diagnostics are rapidly advancing. **Subjects & Methods:** This systematic review and meta-analysis included 164 original articles and provides an overview of the available literature on additional molecular and imaging diagnostics for indeterminate thyroid nodules, including considerations regarding cost-effectiveness, availability, and feasibility of combining techniques. The addressed diagnostic tools include gene mutation analysis, microRNA, immunocytochemistry (ICC), ultrasonography, elastosonography (USE), Tc-99m sestamibi (^{99m}Tc-MIBI) scintigraphy, fluorodeoxyglucose positron emission tomography (FDG-PET) and diffusion-weighted magnetic resonance imaging (DW-MRI). **Results:** The best rule-out tests for thyroid carcinoma were combined galectin-3/HBME-1 ICC (estimated pooled 96.6% sensitivity, 0.04 negative likelihood-ratio (LR)), semi-quantitative USE (92.1%, 0.08), qualitative USE using an alternative threshold score of 1 (98.5%, 0.08), FDG-PET imaging (94.2%, 0.12), and the Afirma® GEC (97.3%, 0.18). The best rule-in tests were BRAF mutation analysis (estimated pooled 99.9% specificity, 195 positive LR), semi-quantitative USE (93.4%, 14.04), combined galectin-3/HBME-1 ICC (94.3%, 13.47), combined BRAF/RAS mutation analysis (94.5%, 8.69) and galectin-3 ICC (90.7%, 7.07). Geographical variations in tumor genetics or cytology (e.g. incidence of Hürthle cell neoplasms) strongly influence several tests. **Discussion:** None of the diagnostics had near-perfect sensitivity, near-perfect specificity and cost-effectiveness. With the techniques currently clinically available, we propose that a multimodal stepwise approach using a sensitive rule-out and a specific rule-in test might offer the most conclusive diagnosis for indeterminate thyroid nodules. There is currently insufficient evidence in literature to reliably interpret sequentially used tests, especially combinations of (molecular) imaging and genetics. Besides choosing two accurate tests to achieve maximum diagnostic accuracy within the local patient population, the sequence of testing and costs of the selected tests and therapeutic procedures are pivotal.

E-PW045

Thyroid hormone withdrawal versus recombinant human TSH administration in radio-iodine therapy of thyroid cancer: comparison of I-131 effective half-life

K. Perisinakis, C. Donas, A. Dimitraki, S. Koukouraki; University of Crete, Medical School, Heraklion, GREECE.

Purpose/Introduction: The discharge time from the treating facility of patients subjected to radioactive iodine I-131 therapy is strongly associated with the residual I-131 activity which is governed by the effective half-life of I-131 ($Teff_{1/2}$). The aim of this study was to determine and compare the effective half-life of I-131 ($Teff_{1/2}$) in thyroidectomised patients subjected to radioiodine therapy after hormone therapy withdrawal or recombinant human TSH administration. **Subjects and Methods:** The patient cohort studied comprised 97 consecutive patients subjected to radio-iodine therapy following thyroidectomy. Administered I-131 dose was 85-200 mCi. Prior to I-131 administration, 3-week long thyroid hormone withdrawal was employed in 57 patients (group A) whereas recombinant human TSH was administered in the rest 40 patients (group B). Data regarding age, sex, weight, height, diet, administered dose were recorded prior to I-131 administration, while volume of water drunk during the first 24h after I-31 administration and size of remnant thyroid tissue were recorded at discharge from isolation room. During hospitalization, the dose rate at the level of diaphragm and 1 m distance from the standing patient was measured with an area monitor. Measurements were collected at 0, 6, 12, 24 and 30 h after I-131 administration. Plots of dose rate against time passed since I-131 administration were fitted to an exponential function and $Teff_{1/2}$ was determined. The $Teff_{1/2}$ of I-131 estimated for patients having been prepared with thyroid hormone withdrawal was compared to corresponding values obtained in patients prepared with recombinant human TSH administration, using Man-Whitney statistical test. **Results:** The mean age of patient group A and B were 46±12 and 49±16 y, respectively. The I-131 $Teff_{1/2}$ estimated for patients prepared by hormone withdrawal and patients administered with recombinant human TSH was found to be 13.4±5.2 h and 10.5±3.9 h, respectively with difference being statistically significantly ($p<0.05$). Age, sex, patient size, diet and dose administered were not found to affect $Teff_{1/2}$. Water consumption and size of remnant thyroid tissue were found to moderately affect $Teff_{1/2}$ but differences did not reach statistical significance. **Discussion/Conclusion:** Elimination rate of residual I-131 activity in thyroidectomised patients treated with radio-iodine may be significantly elevated if patient preparation involves administration

of recombinant human TSH rather than hormone thyroid with-drawal, accelerating patient's discharge from isolation room and decreasing dose received by patient healthy tissues.

E-PW046

Analyisi of long-term clinical follow-up outcome, demographic and histopathological risk factors in a large DTC series

C. Soydal, E. Ozkan, D. Nak, N. O. Kucuk, M. K. Kir; *Ankara University Medical Faculty, Nuclear Medicine Department, Ankara, TURKEY.*

Purpose: To evaluate the relationship between demographic and histopathological prognostic factors and long-term follow-up data of differentiated thyroid carcinoma (DTC) patients. **Material and Methods:** We retrospectively evaluated the long-term clinical follow-up data and baseline demographic and histopathological prognostic factors of our DTC patients. Correlation between gender, age of diagnosis, histopathological subtype, variant and diameter of tumor, multi-centricity, presence of contralateral lobe involvement, thyroiditis, capsule invasion and vascular invasion, TNM stage, ATA and ETA risk groups, preablative serum Tg level and clinical outcome were analyzed. Clinical outcome was classified as poor and good subgroups. Poor subgroup was included persistent and recurrent diseases. Good subgroup was consisted of remission and acceptable disease. **Results:** Totally 2184 (1805 F, 379 M; mean age; 44.24 ± 12.5) patients were included to the analysis. Histopathological subgroups were papillary, follicular, unclassified malign thyroid neoplasm, mixt, thyroid carcinoma with known malign potential in 1972, 131, 41, 32 and 8 patients, respectively. Mean tumor diameter was calculated as 1.66 ± 1.34 cm. While 1421 out of 2184 patients had multicenter tumor, 491 of 2184 patients had contralateral lobe involvement. Capsular and vascular invasion were detected in 1428 and 159 patients respectively. In the evaluation of relationship between histopathological risk factors tumor diameter ($P<0.001$), presence of multi-centricity ($p=0.002$), contralateral lobe involvement ($p<0.001$), capsule invasion ($p<0.001$) and vascular invasion ($p<0.001$) were found statistically correlated with poor clinical outcome. According to TNM staging system, 1850, 162, 172 was staged as 1, 2 and 3. While 1604 patients were low ATA risk group, 580 patients were in intermediate-high risk group. In ETA subgroup analysis, 1757 patients were very low-low risk group and 427patients were in high risk group. TNM stage ($p=0.025$), ATA risk group ($p<0.001$) and ETA risk group ($p<0.001$) were significantly correlated with clinical outcome. Additionally, preablative serum Tg levels ($p<0.001$) had significantly correlated with clinical outcome. **Conclusion:** The relationship between most of the demographic and histopathological risk factors and clinical outcome have been confirmed in our long-term followed up large DTC patient group.

E-PW047

FDG-PET can predict response to vandetanib treatment in patients suffering from advanced medullary thyroid carcinoma

Magdeburg, Magdeburg, GERMANY, ²Klinikum Augsburg, Augsburg, GERMANY, ³LMU München, München, GERMANY.

Introduction: Recently very promising data have been published on redifferentiating radioiodine (RAI) refractory BRAF-mutated papillary thyroid cancer using the selective BRAF-inhibitor dabrafenib in a small study population (1). Here we report on the first experiences with this novel treatment method in Germany. **Subjects & Methods:** We treated two patients with progressive and advanced radioiodine refractory BRAF-mutated papillary thyroid cancer who were not ideal candidates for systemic therapy with tyrosine kinase inhibitors. Previous RAI imaging revealed no uptake in tumor lesions. Both patients received dabrafenib (300 mg/day, compassionate use) for four weeks and had a diagnostic RAI scan after rhTSH stimulation. **Results:** In both patients redifferentiation could be achieved. One patient showed especially intense uptake in diffuse lung metastases. The other patient showed new uptake in a part of a big local relapse in the area of the upper esophageal sphincter. Both patients received therapeutic RAI (9.5 and 11.0 GB) after another 2 weeks of treatment with dabrafenib and stimulation by rhTSH. Posttherapeutic imaging confirmed the results of the diagnostic RAI scan. On follow-up thyroglobuline declined significantly in both patients. The patient with the diffuse lung metastases showed partial response on CT and a decrease in metabolism on PET imaging. In the other patient, the RAI-avid part of the tumor decreased in size, however the non-avid part slightly progressed and a tracheostoma had to be inserted (clinical progress). Dabrafenib and RAI were well tolerated with only minor toxicities. **Conclusions:** Redifferentiation using dabrafenib is a therapeutic option in radioiodine refractory BRAF-mutated papillary thyroid cancer. Patient selection and imaging are important, since, even within one patient, tumor lesions behave heterogeneously in terms of redifferentiation. Reference: (1) Rothenberg et al. Redifferentiation of iodine-refractory BRAF V600E-mutant metastatic papillary thyroid cancer with dabrafenib. Clin Cancer Res. 2015 Mar 1;21(5):1028-35

Lowest effective ¹³¹I activity for lymph node metastases therapy of differentiated thyroid cancer patients; Dosimetry-based model for estimation

V. Stebner, J. Phaosricharoen, K. Herrmann, W. Jentzen; Department of Nuclear Medicine, Medical Faculty, University Duisburg-Essen, Essen, GERMANY.

Aim: A theoretical dosimetry-based model was applied to estimate the lowest effective ¹³¹I activity for lymph node metastases (LM) therapy of differentiated thyroid cancer patients (DTC). **Patients, Methods:** The model is based on the distribution of the absorbed (radiation) dose per administered ¹³¹I activity and the absorbed dose threshold of 100 Gy for LM, the level believed to good response to therapy. The lower activity was considered to be equally effective to that obtained with higher activity if the (absolute) fraction difference was below 5% (Jentzen et al. Nuklearmedizin 2015:54:137). For this purpose,

¹²⁴I-PET/CT images of 36 patients, after thyroidectomy and before first radioiodine therapy, were retrospective analyzed to measure the distribution of the (average) absorbed doses to lymph node metastases per administered ¹³¹I activity between 0.7 and 12 GBq. **Results:** A total of 61 LM were included. The medians and ranges (in parenthesis) for the absorbed dose per unit ¹³¹I activity were 139 Gy/GBq (6 - 1460 Gy/GBq). The fractions of lymph node metastases receiving ≥100 Gy at different therapy activities (within parenthesis) were 80% (3.7 GBq), 93% (6.3 GBq) and 95% (9.6 GBq). The therapy activity of 3.7 GBq is considerably less effective than that of 6.3 GBq or 9.6 GBq; therapy activities were equally effective in the range between 6.3 to 9.6 GBq. **Conclusion:** On the basis of the model and the patients' data included, the lowest effective therapy activity appears to be approximately 6 GBq to therapy lymph node metastases. The results of this study may help to guide the design of prospective clinical trials.

DNA damage in blood leukocytes after internal irradiation with ⁶⁸Ga - in-vivo and in-vitro studies

S. Schumann¹, H. Scherthan², C. Lapa¹, C. Bluemel¹, J. Müller², A. K. Buck¹, M. Port², M. Lassmann¹, U. Eberlein¹; ¹University of Würzburg, Würzburg, GERMANY, ²Bundeswehr Institute of Radiobiology affiliated to the University of Ulm, Munich, GERMANY.

Introduction: The aim of this study was to investigate in-vivo the formation of radiation-induced DNA double strand breaks (DSBs) as a function of the absorbed dose to the blood (AD_{blood}) of patients undergoing PET/CT examinations with the PSMA labelled β⁺-emitter ⁶⁸Ga. Additionally, an in-vitro calibration curve for ⁶⁸Ga was established in order to compare the results. For the quantification of DSBs in blood leukocytes, the co-localizing biomarkers γ-H2AX and 53BP1 were used. **Methods:** For the in-vitro study, different ⁶⁸Ga activity concentrations were added to 37 blood samples of four volunteers to achieve absorbed doses to the blood up to 100mGy after 1h incubation on a roller mixer. For the in-vivo study, blood samples of 13 patients were obtained before and at four different time points after administration of (141 ± 34) MBq ⁶⁸Ga-PSMA. Blood sampling time points were: 15min after administration, directly before the PET/CT scan, directly after and 90-120min after the PET/CT scan. In both cases, leukocytes were isolated from the blood by density centrifugation, washed, fixed and immunofluorescently stained for γ-H2AX and 53BP1. The number of foci showing co-localizing red and green fluorescence for both DSB markers was counted manually. For the calculation of AD_{blood}, the activity in each blood sample was determined with a calibrated germanium detector. For the in-vivo study, additional external dose rate measurements of the patients were performed to determine

the γ-contribution to AD_{blood}. To estimate the CT-contribution to AD_{blood}, the $CTDI_{vol}$ was used. **Results:** For the in-vitro calibration, a linear regression was fitted to the data, which showed a good correlation (r^2=0.90) between the average number of radiation-induced foci (RIF) per cell and AD_{blood}, being in agreement with our calibration curve for β⁻-emitters [1]. In patients, AD_{blood} resulting from ^{68}Ga administration was below 4mGy. However, the number of RIF for the first two time points was higher than predicted by the in-vitro calibration curve. Directly after the CT scan, an increase of RIF was induced by the CT-contribution to AD_{blood} with $CTDI_{vol}$-values in the range of 10-20mGy. **Conclusion:** A linear in-vitro calibration curve for ^{68}Ga was established, but did not represent the RIF-values of the patients in the very low dose range (0.5 - 4mGy). To further improve the estimate of the CT-contribution to the absorbed dose to the blood and for establishing a dose-response relationship, further direct measurements of the CT doses are required. Monte Carlo-Based Bremsstrahlung SPECT Reconstruction for Whole-Liver Dosimetry in Treatments with ^{90}Y-Microspheres - Comparison with ^{90}Y PET

J. Gustafsson[1], K. Knešaurek[2]; [1]Medical Radiation Physics, Clinical Sciences Lund, Lund University, Lund, SWEDEN, [2]Radiology, Icahn School of Medicine at Mount Sinai, New York, NY, UNITED STATES OF AMERICA.

Aim: In this study, the use of Monte Carlo-based bremsstrahlung SPECT reconstruction is compared with ^{90}Y PET for whole-liver absorbed-dose estimation in patients undergoing treatment with ^{90}Y-microspheres. **Materials and Methods:** Fifteen patients were imaged using both bremsstrahlung SPECT/CT (medium-energy collimator, energy window 90 keV ± 15 %) and PET/CT after administration of ^{90}Y-microspheres to the liver (activity range 0.8 GBq to 4.4 GBq). The PET images were reconstructed using OS-EM with 2 iterations, 21 subsets. Volumes of interest following the liver contour were manually defined on the PET/CT images. The outer patient contour was delineated using an automatic method and the injected activity was distributed in the patient volume relative to the PET voxel values. The mean absorbed dose to the liver (including tumours) was calculated assuming local absorption of the charged-particle energy and an assumed density of 1.04 g/cm³. The SPECT images were reconstructed (OS-EM 8 iterations, 10 subsets) using a program based on the SIMIND Monte Carlo code. The program uses SIMIND as an accurate forward projector, thereby including compensation for attenuation, scatter, and imperfect collimation, as well as a model of the overall probability of photon detection in the reconstruction. Hence, the reconstructed images are in units of MBq per voxel even without rescaling or explicit calibration. The SPECT/CT images were co-registered with the PET/CT images (CT-CT rigid registration) and the mean absorbed dose to the liver was calculated using a) the activity calculated directly in the Monte Carlo-based reconstruction and b) rescaling to the injected activity (as for the PET images). **Results**: Without rescaling of the SPECT, the difference in liver absorbed dose expressed as (SPECT - PET) was (mean ± 1 standard deviation) -3.8 Gy ± 6.9 Gy. The average relative difference was -6.5 % (range -37 % to 21 %). When rescaling the SPECT to the injected activity the corresponding results were -3.7 Gy ± 6.1 Gy and -8.4 % (range -38 % to 18 %). **Conclusions**: Monte Carlo-based reconstruction has the potential to be used for estimation of whole-organ absorbed doses from bremsstrahlung SPECT images. The absorbed doses estimated using Monte Carlo-based SPECT reconstruction are similar to the absorbed doses estimated using ^{90}Y PET with rescaling to the injected activity, both when rescaling the SPECT to the injected activity and when using the activity obtained directly from the reconstruction.

Safety, efficacy and outcome of Y-90-resin-microspheres radioembolization in 73 patients with unresectable intrahepatic cholangiocarcionoma: a single center experience

A. Todica, K. J. Paprottka, F. Schöppe, M. Ingrisch, P. Bartenstein, P. M. Paprottka, H. Ilhan; University of Munich, Munich, GERMANY.

Introduction: Radioembolization (RE) using yttrium-90 (Y-90) microspheres is an accepted and well established therapy option in primary or secondary liver malignancies. In patients with unresectable intrahepatic cholangiocarcinoma (ICC), systemic chemotherapy is often viewed as the only option, although efficacy is limited. Data on the value of RE in patients with ICC are limited and only few data on factors influencing prognosis are available. The purpose of our retrospective analysis was to establish factors influencing progression free survival (PFS) and overall survival (OS). **Methods:** RE was performed in accordance to current procedure guidelines in 73 Patients (103 RE procedures) with unresectable ICC. Radiologic response was evaluated by using Response Criteria in Solid Tumors (RECIST). We investigated the impact of baseline characteristics, clinical/biochemical toxicities according to CTCAE (v 4.0) criteria and response on PFS and OS. **Results:** Treatment in 73 patients (40 male) revealed no major complications. After 3 months 16 patients (22%) showed partial response (PR), 34 (47%) stable disease (SD) and 18 (25%) progressive disease (PD) according to RECIST. Mean PFS post treatment was 10.1 months (95%CI 7.9-12.2 months; median 6.4 months). Mean OS was 18.9 months (95% CI 13.9-23.9 months; median 11.8 months). PFS and OS was significantly prolonged (P < 0.001) in patients with response according to RECIST (PR or SD vs. PD; PFS: 10.5, 10.0 vs. 2.7 months; OS: 15.2, 20.9 vs. 6.6 months) or baseline CHE within regular limits (OS: 14.09 vs. 5.5 months; PFS: 6.93 vs. 3.2 months). Significant longer OS was observed in patients with a tumor burden <25% compared to those with higher tumor burden (>50%;15.2 vs. 6.6 months; P=0.036). Sex and age had no major influence. **Conclusions:** Radioembolization is an efficient and safe treatment option in patients with unresectable ICC. Patients with PR and SD show a significantly longer PFS and OS compared to patients with PD. Additional predictors for prolonged survival are baseline CHE and initial tumor burden.

E-PW053

Quantitative Y-90 PET/CT for Dosimetry in Radioembolization

H. Lim[1], N. Clinthorne[1], M. Conti[2], J. A. Fessler[1], Y. K. Dewaraja[1];
[1]University of Michigan, Ann Arbor, MI, UNITED STATES OF AMERICA,
[2]Siemens Healthcare Molecular Imaging, Knoxville, TN, UNITED STATES OF AMERICA.

Aim: The aim was to evaluate accuracy/precision of Y-90 PET/CT for dosimetry applications with a phantom study mimicking count rates, randoms fractions, scan times, activity distributions and scatter conditions that are typical for patient imaging in radioembolization. **Methods:** Y-90 PET data from 18 patients treated with microspheres (administration 0.6 - 4.2 GBq, trues 80,000 - 400,000, randoms fraction 0.85 - 0.96, scatter fraction 0.37 - 0.75) was the basis for the design of the study: a liver/lung torso phantom with 5% lung shunt, 2 MBq/mL in liver, 3 hepatic lesions (8 and 14 mL spheres, 30 mL ovoid) of 10 MBq/mL as well as low uptake (0.1 - 0.9 MBq/mL) extra hepatic objects in cold torso to assess visibility of inadvertent Y-90 deposition. The phantom was scanned for 30 min on a Siemens Biograph mCT on day0, day2, day5, day7 with total activity of 3.1, 1.8, 0.90 and 0.54 GBq, respectively, with multiple acquisitions at some time points. Data was reconstructed using OSEM with and without PSF modeling, with and without TOF and two scatter scaling options (absolute and normalized to scatter tails in sinogram). Based on contrast-to-noise ratios, 2 iterations (24 subsets) were used without TOF and 1 iteration (21 subsets) with TOF. **Results:** Randoms fractions increased from 0.88 to 0.94 while trues decreased from 363,000 to 74,000 from day0 to day7. Best results for contrast, activity recovery, noise and visibility were obtained with TOF+PSF, while alternative scatter scaling did not significantly impact these measures. With TOF+PSF, field-of-view activity estimated from the image was within 2% on day0, but overestimated by 15% at day7. In background liver, eroded by 2 pixels, activity concentration was estimated within 3% at all count-rates while noise ranged from 28 to 64%. Across all count-rates, activity recovery in CT-defined VOIs ranged from 85 - 88% for the liver (improved to 92 - 95% when outline was expanded by 2 pixels), 79 - 83 % for the largest lesion and 64 - 70% for the smallest lesion while repeatability of liver/lesion activity from multiple realizations was within 4 - 18% (all degraded values correspond to lower count-rates). **Conclusion:** Evaluations under clinically realistic conditions demonstrate that Y-90 PET/CT with state-of-the-art systems is suitable for lesion/liver dosimetry, but noise as well as activity underestimation and hence dose underestimation due to resolution effects and potential positive bias in reconstruction algorithms (e.g., due to nonnegativity constraint), should be considered.

E-PW054

Initial Experiences with Post-Interventional Imaging of Residual Yttrium-90 Activity Within Microsphere Delivery Systems using Next-Generation Digital Photon Counting PET/CT Technology

C. L. Wright[1], K. Binzel[1], J. Zhang[1], D. Konate[1], P. Maniawski[2], M. V. Knopp[1]; [1]The Ohio State University, Columbus, OH, UNITED STATES OF AMERICA, [2]Philips Healthcare, Cleveland, OH, UNITED STATES OF AMERICA.

Purpose/Introduction: Following interventional administration of Yttrium-90 (90Y) microspheres, there are typically ultra-low doses of residual 90Y activity left within the delivery system. Infrequently, residual 90Y activity within the delivery system can be higher than expected and direct examination of the radioactive delivery system may be needed to understand where the remaining 90Y activity is distributed. Yttrium-90 produces a small fraction of discrete photon pairs which can be imaged using PET technology. The aim of this study was to evaluate and assess residual 90Y activity within microsphere delivery systems using a pre-commercial release digital PET/CT (dPET/CT) system. **Subjects & Methods:** In this study, 25 microsphere delivery systems were imaged following radioembolization using a pre-commercial release dPET/CT (Vereos, Philips) to detect/localize 90Y activity. Estimated residual 90Y activities within the delivery systems were 5 - 272 MBq. Each delivery system was imaged using a single bed position in list-mode for 60 min and 7 min. List-mode clipping of the 60 min data sets were performed to reconstruct faster acquisition times (i.e., 50 to 1 min). Datasets were reconstructed with ToF using standard definition voxel lengths of 4mm. Matched comparison of dPET image characteristics for actual and subsampled data sets was performed by a reader panel. **Results:** The dPET detection of ultra-low 90Y activity within microsphere delivery system following radioembolization is practical and yields evaluable images. Residual 90Y activity was consistently detected in the source vial and sometimes in the catheter tubing when correlated with CT imaging. List-mode clipping of the 60 min dPET data sets confirmed that subsampled dPET data sets were visually similar to the 7 min true acquisition. When subsampled data sets shorter than 5 min were evaluated, there was progressive loss of the residual foci of 90Y activity within the delivery system when compared with the true 7 and 60 min acquisitions. **Discussion/Conclusion:** These results demonstrate that ultra-low levels of residual 90Y activity within microsphere delivery systems can be reliably detected and imaged using dPET/CT with image acquisition times comparable or even shorter than routine FDG PET/CT studies (i.e., 7-10 min). Further reduction in image acquisition time can significantly impact the visual detection of residual 90Y activity within the delivery system. This approach enables the rapid and precise assessment of 90Y activity within a delivery system in those instances when residual activities are greater than expected or in the case of a 90Y misadministration.

223Ra-Chloride Therapy: The First Multidisciplinary and Multicenter Italian Study

G. Boni[1], S. Mazzarri[1], C. Cianci[2], L. Galli[1], A. Farnesi[1], E. Borsatti[3], R. Bortulus[4], L. Fratino[5], C. Giobitti[4], E. Lamaj[5], P. Ghedini[6], E. Rodi Rizzini[6], V. Dionisi[7], S. Fanti[6], D. Volterrani[1], F. Monari[7]; [1]Nuclear Medicine Department, pisa, ITALY, [2]Medical Oncology Division, pisa,

ITALY, ³Nuclear Medicine Unit, aviano, ITALY, ⁴Radiotherapy Unit, aviano, ITALY, ⁵Medical Oncology, aviano, ITALY, ⁶Nuclear Medicine Department, bologna, ITALY, ⁷Radiotherapy Unit, bologna, ITALY.

Background. Radium-223 (^{223}Ra)-chloride, a novel alpha emitter, has been shown to improve overall survival (OS), to delay skeletal-related events and to reduce pain in patients (pts) with castration-resistant prostate cancer (CRPC) and bone metastases. Our retrospective observational study is the first multidisciplinary and multicenter Italian experience, where the efficacy and safety of ^{223}Ra therapy are evaluated in daily medical practice. **Materials and Methods.** Between August 2013/August 2016, 83 pts with metastatic CRPC (mCRPC) received ^{223}Ra therapy at three Italian Centers. ^{223}Ra-chloride (50 kBq/Kg or 55 kBq/Kg according to NIST2015) was administered every four weeks up to the programmed six cycles of therapy. Study's endpoints were OS, progression-free survival (PFS), pain according to a numeric rating scale (NRS), biomarker response, numbers of symptomatic skeletal-related events (SSEs) and toxicity. **Results.** Median age was 75 (range 53-89) years. The majority of pts had a Gleason score of 7 (n=25), 8 (n=16), or 9 (n=21). Forty-one pts completed 6 cycles of treatment; 33 discontinued treatment after 1 (n=7), 2 (5), 3 (7), 4 (5) or 5 (9) cycles. 9 were under treatment during data collection. NRS pain scores significantly improved during 6 cycles of therapy ($p < 0.000001$). Mean OS was 10.1 months; median OS had not been reached at time of reporting. Kaplan-Meier estimates for OS and PFS were 17.5 and 7.7 months, respectively. OS and PFS were significantly associated with number of ^{223}Ra cycles; most benefit occurred in pts who received all 6 cycles. By stratifying pts according to ALP's levels (≥220 and < 220), a significant difference was found between two groups in terms of expected OS and PSF according to Kaplan-Meier estimation. ^{223}Ra was well tolerated, no serious adverse events occurred during treatments. **Conclusion.** ^{223}Ra represents an important treatment option for pts with CRPC and symptomatic bone metastases and it seems to be useful in improving OS, PFS and level of pain; especially OS and PFS were better in pts with a lower tumor burden according to ALP levels.

Age-adjusted risk factors for patients undergoing molecular radiotherapy

J. Thurston, G. Flux; Royal Marsden Hospital, London, UNITED KINGDOM.

Purpose/Introduction: With advances in medicine, including in radionuclide therapies, the prognosis for patients suffering from a range of cancers, both for solid tumours and leukaemias, has improved significantly over the past few decades. However the implication of such improved prognoses is that the long-term risks from radionuclide therapy of inducing a second primary cancer later in life can no longer be considered to be negligible for these cohorts of patients, when carrying out Justification and when gaining informed consent from patients. **Subjects & Methods:** Whole body absorbed doses were obtained from the literature for a range of radionuclide therapies, for comparison with published ICRP data on the Effective Dose per administered activity [1] and risk coefficients for fatal cancer resulting from radiation exposure to estimate the lifetime risks associated with these procedures, including age-adjusted risk factors [2] to take into account the age of the patient when treated. The results were then further adjusted to take into account life expectancy post-therapy in relation to minimum latency periods for any radiation-induced leukaemias and solid tumours to develop. Thus risk factors were calculated as a function of the administered activity, age at treatment, and maximum life expectancy. **Results:** The wide range of absorbed doses delivered from fixed or weight based activities lead to a correspondingly wide range of potential risks, exacerbated by the range of life expectancies that are difficult to predict. Nevertheless, it is possible to generate a table of values that, although not pertaining to individual patients, may be used for reference. Example: for an administered activity of 7.4GBq I-131 labelled mIBG to treat neuroblastoma in paediatric patients and young adults, and using a published whole body absorbed dose range of 0.04 - 0.63mSv/MBq [3]. **Discussion/Conclusion:** The results indicate the range of theoretical risks suffered by patients undergoing radionuclide therapy, taking into account both the age of the patient at exposure, and their life-expectancy post-therapy. These may be used to inform Practitioners so that they can be considered as part of the Justification and Consenting processes. **References:** 1. ICRP53 + Addendums 2. ICRP103 3. Flux GD *et al*. Clinical applications of dosimetry for mIBG therapy *Q J Nucl Med Mol Imaging* 55(2), pp 116-125, 2011.

Renal toxicity analysis in a Peptide Receptor Radionuclide Therapy (PRRT) trial with alternated 177Lu and 90Y-DOTATOC

*E. Grassi*¹, F. Fioroni¹, M. Cremonesi², D. Finocchiaro¹,³, M. Ferrari², F. Botta², G. Castellani³, N. Lanconelli³, A. Filice⁴, A. Versari⁴, M. Iori¹; ¹Medical Physics Unit, Arcispedale Santa Maria Nuova-IRCCS, Reggio Emilia, ITALY, ²Medical Physics Unit, European Institute of Oncology, Milan, ITALY, ³Dept. of Physics, University of Bologna, Bologna, ITALY, ⁴Nuclear Medicine Unit, Arcispedale Santa Maria Nuova-IRCCS, Reggio Emilia, ITALY.

Purpose: To analyze the renal toxicity in a PRRT trial (follow-up>12 months) and to explore the dose-effect correlation in terms of normal tissue complication probability(NTCP). **Subjects & Methods:** The trial consisted in alternation of 177Lu and 90Y-DOTATOC, with activity proportion based on the patient characteristics and dosimetry. A cohort of 51 patients was recruited and divided into 2 classes: 30 patients with risk factors (hypertension, diabetes, chemotherapy), RF, and 21 without (noRF). All patients underwent organ level 3D-dosimetry study (MIRD16), after a therapeutic administration of 177Lu-DOTA-TOC (5 SPECT-CT acquisitions, Siemens-SymbiaT2). Kidney cumulative dose D, and Biological Effective Dose BED were calculated. Creatinine was assessed from blood chemistry at definite intervals up to at least 6 months after the last injection,

and creatinine clearance loss (CCL) was derived. Renal acute and chronic toxicity grade were assessed (CTCAE 4.0). NTCP curves were estimated using a probit model. **Results:** Patients were administered on average with 27% of 90Y-DOTATOC and 73% with 177Lu-DOTATOC. Kidney cumulative dose D, and BED were (mean value+/-SD) 22.7Gy+/-1.7 and 24.6Gy+/-2.2, respectively. Cumulative BED to D ratio was approximately 1.1 for both 177Lu- and 90Y. The mean+/-SD follow up period was 87+/-37 w (range 51-235w). Only G1 acute toxicity was observed in 7 patients (17% RF, 10% noRF). Low chronic toxicity was observed in noRF patients (G1=3, G2=1) and was more frequent in RF patients (G1=9, G4=1). Considering all patients, the mean CCL was 3%, 6%, 9%, 13% at 6, 12, 18, 24 months. In particular mean CCL% at 2y was 14% in RF patients and 8% in no RF patients. Higher number of cases with CCL>20%/y was observed in patients with RF (19%) compared to patients noRF (10%). Similarly with CCL>10%/y (38% RF, 29% noRF patients). The recovery of the initial creatinine value (i.e. CCL<0%) was observed in 28% of RF cases and in 24% of noRF patients. BED values (C.I.) of 35Gy(29-52), 32Gy(21-248), provided chronic NTCP of 50% for noRF and RF, respectively (significant p<0.05). **Conclusions:** Chronic toxicity was of low grade in most cases: G1 observed in 24% of pts, while higher toxicity grades were quite rare (2% G2; 2% G4). Different NTCP curves for chronic toxicity were derived for the two populations considered. For acute toxicity, poor correlation was observed between creatinine increase and dose in noRF patients. No correlation was found when all patients were considered. Work partially supported by EMPIR-MRTDosimetry project(15HLT06), co-funded by EU's Horizon-2020-programme.

E-PW058

3-Dimensional Dose Mapping after PRRT with 177Lu-DOTATATE/-TOC by One-Single Measurement after Four Days

R. A. Werner[1,2], C. Lapa[1], A. K. Buck[1], M. Lassmann[1], H. Hänscheid[1]; [1]Department of Nuclear Medicine, Universitätsklinikum Würzburg, Würzburg, GERMANY, [2]Johns Hopkins School of Medicine, The Russell H Morgan Department of Radiology and Radiological Science, Baltimore, MD, UNITED STATES OF AMERICA.

Introduction: We analyzed the accuracy of absorbed dose estimates based on one-single measurement of the activity retention in a cohort of patients treated with PRRT. **Subjects and Methods**: Activity kinetics (67 kidneys, 30 livers, 34 spleen, 52 tumors) were analyzed in patients with repeated planar whole body scans (1-4 h, 1 d, 2 d, and ≥4 d) after ^{177}Lu-DOTATATE/-TOC administration. A bi-exponential decay function was fitted to the data of each evaluable organ/tumor r_S and normalized to 100% at its maximum to deduce the relative uptake $u(r_S,t)$. This function, after integration over time to deduce the time integrated uptake $\tilde{u}(r_S)$ and normalization to a high-quality quantitative retention measurement e.g. with a SPECT/CT, can be used to determine the absorbed dose to r_S. For a function $u(r_S,t)$ decaying mono-exponentially with an effective half-live T_{eff}, $\tilde{u}(r_S)$ can be approximated by $\tilde{u}(r_S) \approx \tilde{u}_I(r_S,t_I) = u(r_S,t_I) \cdot t_I \cdot 2/\ln(2)$ from a single measurement $u(r_S,t_I)$ at a late time point t_I (1). The error is theoretically < 6% if $0.85 \cdot T_{eff} < t_I < 1.17 \cdot T_{eff}$. For each uptake function, the values $\tilde{u}_I(r_S,t_I)$ were calculated from the expected $u(r_S,t_I)$ at t_I = 24 h, 48 h, 72 h, 96 h, 120 h, and 144 h and the deviations from $\tilde{u}(r_S)$ were determined. The mean tissue specific error was calculated for each time point t_I. **Results:** For a measurement at t_I = 96 h, the deviation of $\tilde{u}_I(r_S,t_I)$ from $\tilde{u}(r_S)$ was determined to be 5% ± 6% (range, -9% to 20%) for kidneys, 7% ± 5% (range, -1% to 20%) for livers, 11% ± 8% (range, 2% to 47%) for spleens, and 2% ± 8% (range, -28% to 16%) for tumors. Accuracy is slightly reduced for measurements after 72 h (kidneys: 9% ± 6%; range, -15% to +25%) or 120 h (kidneys: -5% ± 8%; range, -25% to 8%). Inacceptable underestimates of the absorbed dose to the kidneys are observed for measurements after 24 h (-33% ± 7%; range, -61% to -18%), 48 h (0 ± 8%; range, -33% to 19%), and 144 h (-18% ± 10%; range, -41% to 7%). For calculating the absorbed dose, an activity concentration of 1 MBq/g measured in a tumor at 96 h indicates a local absorbed dose of 24 Gy. **Conclusion:** A quantitative image of the abdominal activity concentration distribution in a patient 4 days after the administration of ^{177}Lu-DOTATATE/-TOC is proportional to a map of the absorbed doses to tumors/relevant organs.

E-PW059

Bone metastases affect bone marrow response during 177-Lu-DOTATATE treatments

J. Svensson[1], L. Hagmarker[2], T. Rydén[2], R. Hermann[2], B. Wängberg[3], A. Sundlöv[4], K. Sjögreen-Gleisner[5], P. Bernhardt[2]; [1]Institution of Clinical Sciences, Dep of Oncology, Göteborg, SWEDEN, [2]Institution of Clinical Sciences, Dep of Radiation Physics, Göteborg, SWEDEN, [3]Institution of Clinical Sciences, Dep of Surgery, Göteborg, SWEDEN, [4]Clinical Sciences, Dep of Oncology and Pathology, Lund, SWEDEN, [5]Clinical Sciences, Dep of Radiation Physics, Lund, SWEDEN.

Treatment with 177-Lu-DOTATATE has proven safe according to renal function also in long time follow up, and the stated absorbed dose limits for the kidneys are being challenged. The bone marrow response to treatment is usually described as mild, but clinically relevant bone marrow toxicity does appear during treatment. Persisting bone marrow toxicity may also limit the amount of treatment cycles possible to give, and adventure future treatment options. The aim of this work was to examine if bone marrow response during the first treatment cycle could predict persisting bone marrow toxicity in the remaining treatment cycles. Patients with and without bone-metastases were also compared according to bone marrow response during treatment. **Subjects and Methods:** To date 95 patients with progressive disease of advanced SSTR-positive neuroendocrine tumours have been included in the ILUMINET study (EUDRACT nr 2011-000240-16) and treated with 177-Lu-DOTATATE in a renal dose-escalation study. 40 patients have been included in the present analyse. Post treatment planar images (2 h, 24 h, 48 h, 168 h) were used in the in-house developed image based two-compartment method for calculation of bone marrow doses. To evaluate bone marrow function and its response to treatment, biomarkers including Hb, WBC and PLT counts were

analysed baseline and weekly during all treatment cycles. **Results:** Patients with bone metastases did not receive higher absorbed bone marrow doses during treatment, but did experience more bone marrow toxicity according to platelet counts (p<0.05). Five of the six patients who had to stop treatment due to persisting leukopenia or thrombocytopenia had bone metastases. These six patients responded to the first treatment cycle more markedly showing a more pronounced decrease in platelet counts compared to the patients that could be treated as planned (p<0.0001). The decrease in white blood cells did not differ between patients with and without bone metastases, but the decrease per absorbed dose to the bone marrow was more significant for patients with bone metastases(p=0.04). This was even more pronounced for the six patients who could not receive full treatment (p=0.02). The response according to Hb counts did not differ between the groups. **Conclusions:** The more pronounced decrease in platelet counts and WBC counts per absorbed dose to the bone marrow indicates a higher individual bone marrow radiosensitivity for patients with metastases. This response pattern will be further analysed as a tool to predict bone marrow toxicity.

<0.01 to 4379 ng/mL at baseline and 0.02 to 596.3 ng/mL at follow-up. There was no correlation between NaF SUV and PSA at baseline or over time. In contrast, maximum and mean SUVs correlated to PSA at baseline (p<0.01) but changes at follow-up were not significant. At baseline, 18F NaF identified 180 (98.4%) bone lesions while 18F DCFBC detected 84 (45.7%) at 1hr and 85 (47.2%) at 2hrs. At follow-up, 18F NaF detected 120 (97.6%) and DCFBC identified 52 (44.1%) at 1hr and 55(44.4%) at 2hrs. There was no SUV correlation between the two tracers. In addition, DCFBC demonstrated focal uptake in 56 soft tissue or lymph node lesions at baseline, and at follow-up identified 40 non-osseous lesions at 1hr and 41 similar lesions at 2hrs. Conclusion: NaF had significantly higher bone lesion detection rate than DCFBC, however, this scan provides no information regarding the biological activity of each lesion. In contrast, 18F DCFBC demonstrated active metastatic lesions. 18F DCFBC was also capable of recognizing both bone and soft tissue metastases with slightly better performance at 2hrs than 1hr post injection. At baseline, PSA correlated with SUVs for DCFBC but not with NaF SUVs. 18 NaF represents both active and inactive lesions whereas 18F DCFBC provides better evidence of active metastases. PSMA agents hold great promise for characterizing all phases of prostate cancer.

Detecting Prostate Cancer Bone Metastasis With 18F DCFBC (a PSMA Targeted Agent) Compared to 18F Sodium Fluoride

L. Lindenberg[1], E. Mena Gonzalez[1], I. Turkbey[1], J. Shih[1], E. Bergvall[2], A. Lindenberg[3], W. Dahut[1], M. Pomper[4], P. Choyke[1]; [1]National Cancer Institute, Bethesda, MD, UNITED STATES OF AMERICA, [2]Fort Belvoir Community Hospital, Ft Belvoir, VA, UNITED STATES OF AMERICA, [3]Fort Belvoir Community Hospital, Fort Belvoir, VA, UNITED STATES OF AMERICA, [4]Johns Hopkins University School of Medicine, Baltimore, MD, UNITED STATES OF AMERICA.

Aim: Prostate Specific Membrane Antigen (PSMA) is overexpressed in aggressive prostate cancers and is actively being pursued as an imaging and therapeutic target. 18F DCFBC is a radiolabeled PET agent that binds with high affinity to PSMA. We compared bone metastasis detection in prostate cancer patients with 18F NaF and 18F DCFBC. Materials and methods: Subjects with known or suspected prostate cancer metastases underwent 18F DCFBC PET/CT imaging performed at 1 and 2 hours post injection (p.i.) of 8 mCi 18F DCFBC. Patients also underwent a whole body 18F NaF PET/CT scan one hour p.i. of 3mCi 18F NaF within 3 weeks. Dual tracer imaging was repeated at 4-6 months. Maximum and mean Standardized Uptake Values (SUVs) were obtained for all lesions with both radiotracers. PSA levels were obtained at the time of 18F DCFBC imaging. Statistical analysis was performed with Spearman rank correlation. Results: There were 28 evaluable patients. PSA ranged from

177Lu-DOTA-octreotate Therapy of Advanced Pancreatic Neuroendocrine Tumors - a Single Centre Experience

K. Fröss-Baron[1], U. Garske-Roman[2,3], S. Welin[1], D. Granberg[1], B. Eriksson[1], M. Sandström[3], A. Sundin[3]; [1]Department of Medical Sciences, Uppsala University, Uppsala, SWEDEN, [2]Department of Clinical Physiology, Sahlgrenska University Hospital, Gothenburg, SWEDEN, [3]Department of Surgical Sciences, Uppsala University, Uppsala, SWEDEN.

Aim: To study progression-free survival (PFS) and overall survival (OS) and their determinants in a consecutive cohort of patients with inoperable, advanced pancreatic neuroendocrine tumours (pNET) treated with 177Lu-DOTA-octreotate in one centre. **Material and Methods:** A total of 125 consecutive patients with inoperable, metastatic pNET were treated with 177Lu-DOTA-octreotate between November 2005 and October 2014. We excluded 23 patients for final efficacy analysis: 11 patients with missing follow-up, 12 patients who could not receive more than 2 treatment cycles because of either side effects or general deterioration. The final cohort of 102 patients received 3-10 cycles at 6-8 weeks interval with mean activity 29.6 GBq (range 17-74). A total of 82 (80.4%) patients were treated according to a dosimetry-guided protocol. Out of the 102 patients, 72 (70.6%) were non-functioning, 86 (84.3%) had progressive disease before inclusion, 94 (92.1%) had received chemotherapy before PRRT (52.1% of whom more than one line of therapy) and 43 (42.1%) had their primary tumour resected. There were 9.2% G1 tumours, 83.9% G2 tumours and 6.9% G3 tumours. Mean follow up was 42 months (range 4-129). Response was evaluated according to RECIST 1.1 criteria. Toxicity analysis was assessed in the whole group of 125 patients (WHO criteria). **Results:** Median

PFS and OS were 27.5 months (95%CI 23-31) and 42 months (95%CI 31-51) respectively. Primary tumour surgery and stable disease prior to therapy start were associated with longer PFS and OS. Ki67<10% was additionally associated with longer PFS but not OS. Best morphological therapy response was as follows: Complete response (CR) in 6 patients (5.9%), partial response (PR) in 52 (51%), stable disease (SD) in 38 (37.2%), progressive disease (PD) in 6 (5.9%). Morphological response (PR+CR) correlated with longer PFS (p=0.02) and OS (p=0.0006) than stable disease (SD). In a subgroup with dosimetry-guided therapy protocol, patients reaching an absorbed dose of 23 Gy to kidneys had significantly longer PFS and OS. Any bone marrow toxicity grade 3 or 4 occurred in 17 (13.6%) pts, one patient developed fatal liver toxicity. No significant nephrotoxicity (grade 3 or 4) was observed. **Conclusions:** 177Lu-DOTA-octreotate therapy is effective in patients with advanced pNET with a median PFS of 27.5 months and a median OS of 42 months. Patients obtaining 23 Gy to kidneys and patients with morphologic response have PFS and OS benefits. In agreement with other reports, reversible bone marrow toxicity is the most frequent toxicity of this treatment.

E-PW062

The Value of Somatostatin Receptor Imaging (SRI) in Patients with NENG1/G2 Pancreatic Neuroendocrine Neoplasms (pNENs) Base on Pathological and Clinical Follow-up.

S. J. Konsek[1], A. Kolasinska-Cwikla[2], A. Lewczuk[3], L. Sawicki[2], M. Kidd[4], A. Cichocki[2], A. Nasierowska-Guttmejer[5], M. Tenderenda[2], J. B. Cwikla[1], I. M. Modlin[6]; [1]Faculty of Medical Sciences, University of Warmia and Mazury, Olsztyn, POLAND, [2]MSC Memorial Cancer Centre and Institute Maria Sklodowska-Curie, Warsaw, POLAND, [3]Medical University of Gdansk, Gdansk, POLAND, [4]Wren Laboratories, Branford, CT, UNITED STATES OF AMERICA, [5]Hospital Ministry of Internal Affairs, Warsaw, POLAND, [6]Yale University, New Haven, CT, UNITED STATES OF AMERICA.

Background: Neuroendocrine neoplasms of the pancreas (p-NEN) are common origin of GEP-NEN. The aim of this retrospective study was to review the of value of Somatostatin Receptor Scintigraphy (SRS) in initial detection and tumour extent of well and moderate differentiated (NENG1/G2) tumours in patients with confirmed p-NEN, based on histology and further clinical and/or biochemical follow-up. **Subjects and Methods:** There were 247 patients with confirmed p-NEN. The SRS was performed to evaluation of primary p-NEN, also to assess clinical stage of disease, based on current WHO classification. Overall, 696 examinations in this group of subjects were performed using 99mTc HYNICTOC (Octreotide, NCBJ; Polatom, PL). Initially whole body WB-SPECT and then WB-SPECT/CT, with standard iterative reconstruction were used in each case. **Results:** There were 143 pts with NENG1 (58%) and 104 pts with NENG2 (42%). In 58 patients (23%) with NENG1/2 seventy-two (10%) SRS were performed to assessed initial diagnosis. There were 70 (97%) true positive (TP), 2 (3%) false negative (FN), no true negative (TN) and false positive (FP) results of examinations by SRS. Sensitivity

of SRS per patient as diagnose of neoplasm is 97%. In 175 pts (71%) SRS was used in evaluation of clinical stage. Overall 548 (79%) examination were performed in this group of pts. There were TP=422 (77%), TN=115 (21%), FN=7 (1%) and FP=4 (1%) results. Sensitivity and specificity of SRS per study in evaluation of tumour extent is as follows: sensitivity 98%, specificity 97%; per patient: sensitivity 95%, specificity 94%. In 34 pts (14%) SRS was used as imaging follow-up after radical surgery, there were overall 76 (11%) studies carried out. There were 95% TN results of examinations of SRS and in 4 pts we identified the reccurance of the tumour. In total, in group of diagnose/staging and follow-up the sensitivity, specificity and accurancy of the test was 98% per study. Per patient: sensitivity 96%, specificity 97% and accurancy of the test 96%. **Conclusion:** SRS using 99mTc HYNIC-TOC acquired in WB-SPECT or WB-SPECT/CT techniques seems to be highly sensitivity and specificity and had great value as examination to evaluate in both the detection of primary p-NEN and to assess clinical stage of disease in patients with well or moderate differentiated p-NEN. The highest specificity of the test was noted in the group of patients that SRS was performed to assessed initial diagnosis and helped correctly identify those patients without the disease.

68Ga-PSMA-11 PET/CT in the evaluation of bone metastases in prostate cancer

C. Sachpekidis[1], P. Bäumer[2], B. A. Hadaschik[3], U. Haberkorn[1], A. Dimitrakopoulou-Strauss[1]; [1]Clinical Cooperation Unit Nuclear Medicine, German Cancer Research Center (DKFZ), heidelberg, GERMANY, [2]2Department of Radiology, German Cancer Research Center, DKFZ, heidelberg, GERMANY, [3]Department of Urology, University Hospital Heidelberg, heidelberg, GERMANY.

Aim: To compare the 68Ga-PSMA-11 PET with the ultra low-dose CT (80 kV, 30 mA) findings, as well as to provide semi-quantitative and quantitative 68Ga-PSMA-11 PET data, in bone metastases of prostate cancer (PC). **Methods:** In total 147 PET/CT scans of 137 patients were extracted from our database. 109 patients had biochemical failure after primary PC treatment with curative intent, while 28 patients suffered from primary, previously untreated PC. All patients underwent dynamic PET/CT (dPET/CT) scanning of the pelvis as well as whole-body PET/CT with 68Ga-PSMA-11. Dynamic and whole-body PET/CT assessment was based on qualitative evaluation and SUV calculation. Moreover, dPET/CT data from the pelvis underwent quantitative analysis based on a two-tissue compartment model and a non-compartmental approach leading to the extraction of fractal dimension (FD). **Results:** In total, 141 68Ga-PSMA-11 avid lesions consistent with bone metastases were detected with PET. 78 of these lesions showed a correlate on low-dose CT. On the other hand, 9 lesions were CT-positive but 68Ga-PSMA-11 PET-negative. 2 patients demonstrated disseminated skeletal 68Ga-PSMA-11 uptake, one of which with much less metastases-indicative CT findings. The mean (range) of $SUV_{average}$ and SUV_{max} for 68Ga-PSMA-11 avid bone lesions were 13.2 (1.9 - 95.0) and 20.9 (2.8 - 133.6) respectively. Dynamic PET/CT studies of

the pelvis revealed 63 lesions indicative of bone metastases with the following mean values: $K_1 = 0.21$, $k_3 = 0.28$, influx = 0.13 and FD = 1.23. In most bone lesions time-activity curves revealed an increasing ^{68}Ga-PSMA-11 accumulation during dynamic PET acquisition. The strongest correlations were found between FD and $SUV_{average}$ (r=0.95), FD and SUV_{max} (r=0.92), FD and influx (r=0.84), influx and $SUV_{average}$ (r=0.84), as well as between influx and SUV_{max} (r=0.82) (p <0.0001). A weak but significant correlation was demonstrated between PSA and $SUV_{average}$ (0.36) and SUV_{max} (0.36). Wilcoxon rank-sum revealed no statistically significant difference between bone and lymph node metastases (retrieved from our patient data pool) regarding SUVs and kinetic parameters. **Conclusion:** ^{68}Ga-PSMA-11 PET can reliably depict bone metastases of PC. Many of these bone lesions are missed on ultra low-dose CT. The amount of ^{68}Ga-PSMA-11 uptake in bone metastases correlates very strongly with tracer influx and the degree of heterogeneity of tracer distribution, and weakly with the degree of PSA plasma levels.

E-PW064

PSMA-PET MRI/TRUS robot-guided targeted prostate biopsy for detection and localisation of Primary prostate cancer

M. Mix, K. Schaal, M. Krönig, V. Drendel, U. Wetterauer, W. Schultze-Seemann, C. A. Jilg, P. T. Meyer; University of Freiburg, Medical Center, Freiburg, GERMANY.

Aim: Multiparametric MRI/TRUS-guided biopsy represents the standard tool for prostate cancer (PCa) detection in the setting of re-biopsy following negative primary biopsy. Recently, PSMA-PET/CT was introduced, targeting the prostate-specific membrane antigen (PSMA) on the surface of PCa cells, which enables powerful imaging of PCa lesions. Aim of this study was to evaluate the lesion-based detection rate for PCa from PSMA-PET MRI/TRUS fusion-robot-guided targeted prostate biopsy. **Methods:** Nine patients with tumour suspicious intraprostatic lesions on PET/CT with Ga-68-HBED-CC-PSMA underwent PET/MRI/TRUS fusion-targeted biopsies. 8/9 men received multiparametric MRI (1/9 had no MRI due to cardiac pacemaker). Areas with increased PSMA expression on PET were clinically classified by two nuclear medicine experts as PET-positive lesions (PL: highly suggestive of malignancy; showing intense focal uptake) or as PET-indeterminate lesions (IL: inhomogeneous moderate uptake). Lesions were manually contoured on fused PET/MRI images. Patients underwent a robot-guided transperineal-targeted biopsy (iSR'obot Mona-Lisa/Biobot system) of PET-PL and IL lesions and a standardized volume-adapted random saturation biopsy according to the Ginsburg study group scheme. **Results:** Mean PSA-level at biopsy was 11±4 ng/ml. The average SUV-max values were 9±8 g/ml (4 - 34) in a total of 17 intraprostatic lesions with increased PSMA expression. 9/17 lesions were defined as PL, 8/17 as IL. By histopathology, PCa was diagnosed in 7/9 men (78%). Furthermore, 8/9 (89%) prostate regions defined as PL were positive for PCa. In contrast, all 8 regions defined as IL were free of PCa. 3/8 lesions with proven PCa would have been missed by random biopsy only (lesions were not covered

by Ginsburg scheme), whereas 3 additional (PET-negative) PCa lesions had been diagnosed exclusively via random biopsy. Gleason score distribution for all PCa lesions was 2/12 (Gleason 6), 5/12 (Gleason 7a), 1/12 (Gleason 7b), 3/12 (Gleason 8), 1/12 (Gleason 9). PCa-diagnosis would have been possible in 7/7 patients by applying target biopsy only, in 6/7 men by applying random biopsies only. One patient was diagnosed with PCa (Gleason 8) with targeted biopsies only. **Conclusion:** PSMA-PET MRI/TRUS fusion-guided biopsy demonstrates strong potential for PCa detection in patients with tumour suspicious lesions on a PSMA-PET/CT after a negative primary biopsy. Targeting lesions with intense focal uptake on PSMA-PET with our biopsy system ensured high probability for PCa diagnosis, whereas lesions with only inhomogeneous moderate PSMA expression were not indicative of for PCa. The application of a limited number of PET-targeted biopsies leads to PCa diagnosis in nearly all patients.

E-PW065

Usefulness of 18F-choline PET/CT to evaluate patients eligible for Radium-223 Dichloride Therapy

E. Biggi[1], C. Fuccio[1], F. Ottalevi[1], F. D'Emidio[2], L. D'Angelo[3], A. Berbellini[1]; [1]Nuclear Medicine Unit, Ospedale "C. G. Mazzoni", Ascoli Piceno, ITALY, [2]Diagnostic Radiology Unit, Ospedale "C. G. Mazzoni", Ascoli Piceno, ITALY, [3]Medical Physics Unit, Ospedale "C. G. Mazzoni", Ascoli Piceno, ITALY.

Aim: 99mTc-diphosphonate whole-body bone scintigraphy (BS) and whole-body CT (wbCT) scan are generally used in patients with metastatic castration-resistant prostate cancer (mCRPC) potentially candidate to 223-Ra Dichloride Therapy (223-Ra) in order to evaluate the presence and the extent of metastatic spread to the bones and to exclude the presence of visceral metastases. Main aim of the study was to investigate whether 18F-choline (FCH) PET/CT may have an added value over BS or wbCT in order to correctly select patients eligible for 223-Ra therapy; secondary aim was to evaluate the extent of disease according to ALSYMPCA criteria. **Materials and Methods:** from June 2016 to February 2017, 10 consecutive mCRPC patients (median age 72,4 yr; range 61-84) potentially candidates to 223-Ra treatment were referred to our Centre. All patients showed a progression of skeletal disease at BS (performed within 12 weeks) and no visceral metastases at CT scan (performed within 6 months). All patients underwent FCH PET/CT and a complementary ultra-sound or c.e. CT of the liver. Low-dose co-registered CT images were also evaluated by a radiologist in case of equivocal findings. Patients were classified using ALSYMPCA criteria (I group <6 metastases; II group 6-20 metastases; III group >20 metastases). Validation of results was established by: a positive biopsy, a positive subsequent CT or MR or follow up. **Results:** FCH PET/CT showed unknown visceral metastases in 6/10 cases: cerebellum metastases (1), lung metastases (2), lymph-node involvement greater than 3 cm in the short-axis diameter (2), epidural spine with cord compression (1). These patients were referred to other therapies. FCH PET/CT was also able to give an accurate staging of mCRPC in 4/10 pa-

tients (that underwent 223-Ra therapy) and a better bone lesion detection rate than BS (BS positive in 232 sites vs PET positive in 389 sites), changing ALSYMPCA classification in 3/10 patients (from II to III group). **Conclusion:** FCH PET/CT can provide significant incremental data in mCRPC patients potentially eligible for 223-Ra. FCH PET/CT changed therapeutic management in 6/10 patients leading clinicians to consider other treatment options or to postpone this approach. Main limitation of this study is the small patient population enrolled.

E-PW066

64CuCl2 PET/CT and Fused-64CuCl2 PET/MRI in prostate cancer relapse. Comparison with 18F-Choline PET/CT, Fused-18F-Choline PET/MRI and multiparametric MRI

G. Ferrarazzo[1], G. Bottoni[1], F. Paparo[1], M. Puntoni[1], L. Bacigalupo[1], S. Zanardi[1], A. DeCensi[1], S. Righi[1], E. Lopci[2], M. Cabria[1], A. Piccardo[1]; [1]E.O. Ospedali Galliera, Genova, ITALY, [2]Humanitas Research Hospital, Milano, ITALY.

Aims: to evaluate the biodistribution and radiation dosimetry of 64CuCl2 in humans and to assess the ability of 64CuCl2-PET/CT and Fused-64CuCl2PET/MRI to detect prostate cancer (PCa) recurrence in patients with biochemical relapse. **Materials and Methods:** we prospectively evaluated 50 PCa patients with biochemical relapse after first-line surgery or external-beam radiation therapy. All patients underwent 64CuCl2-PET/CT, 18F-Choline-PET/CT and multiparametric magnetic resonance imaging (mpMRI) within 15 days of each other. Fused-64CuCl2PET/MRI and Fused-18F-Choline-PET/MRI images were obtained by co-registration of MRI and PET images using a dedicated software. The detection rate (DR) of each imaging modality was calculated by using histopathology, clinical or laboratory response and multidisciplinary follow-up as a reference standard. Biodistribution and Radiation dosimetry of 64CuCl2 were evaluated by means of three PET/CT acquisitions: 1, 4 and 24 hours after tracer injection. **Results:** 64CuCl2 is not excreted nor accumulated in the urinary tract, thus allowing thorough pelvic exploration. A 64CuCl2 of a 200 MBq injection translates to 5.7 mSv effective dose. In our cohort, 64CuCl2-PET/CT proved positive in 41 of 50 patients, with an overall DR of 82%. The DRs of 18F-Choline-PET/CT, mpMRI, 64CuCl2-PET/MRI and 18F-Choline-PET/MRI were 56%, 74%, 88% and 68%, respectively. The difference between the DRs of 64CuCl2-PET/CT and 18F-Choline-PET/CT was statistically significant (p=0.002). Significant differences were also found between the DRs of Fused-64CuCl2-PET/MRI and Fused-18F-Choline-PET/MRI (p=0.001) and between 64CuCl2-PET/MRI and mpMRI (p=0.023). Interestingly, on considering PSA value, 64CuCl2-PET/CT had a higher DR than 18F-Choline-PET/CT in patients with PSA <1 ng/ml . **Conclusions:** The biodistribution of 64CuCl2 is more suitable than that of 18F-Choline for exploring the pelvis and prostatic bed. The 64CuCl2 effective dose is similar to those of other established PET tracers. In patients with biochemical relapse and a low PSA level, 64CuCl2-PET/CT shows a significantly higher DR than 18F-Choline- PET/CT. In this comparative study, 64CuCl2-PET/MRI achieved the best diagnostic results.

E-PW067

Additional value of early ^{68}Ga-PSMA-11 PET Imaging in the assessment of local recurrence in prostate cancer patients with biochemical recurrence

C. Uprimny, A. S. Kroiss, J. Fritz, C. Decristoforo, E. vonGuggenberg, B. Nilica, J. Bektic, W. Horninger, I. J. Virgolini; Medical University Innsbruck, Innsbruck, AUSTRIA.

Purpose: Evaluation of local recurrence (LR) in prostate cancer patients with biochemical recurrence may be hampered by high physiologic urinary bladder activity present on 68Ga-PSMA-11 (HBEDD-CC) PET/CT exams, usually conducted 60 min after tracer injection (p.i.). This study aims to investigate whether early static PET scans could enhance diagnostic performance of 68Ga-PSMA-11 PET/CT in the detection of LR in comparison to PET imaging 60 min p.i.. **Methods:** 213 prostate cancer patients with biochemical recurrence referred to 68Ga-PSMA-11 PET/CT were analysed retrospectively (median PSA: 1.47 ng/ml). In all patients an early static scan of the pelvis was performed with a median starting time of 281 sec p.i. (range: 215-491 sec), followed by a whole-body PET/CT 60 min p.i.. Image interpretation was based on visual analysis. Furthermore calculation of maximum standardized uptake value (SUV_{max}) of pathologic lesions present in the pelvic region was performed on early PET images and on 60 min-PET scans. **Results:** On PET images 60 min p.i a LR-suggestive lesion (median SUV_{max} of 11.0; range: 4.7 - 40.9) could be detected in 28 patients (13.1 %), whereas an equivocal finding was present in 36 patients (16.9 %). In contrast, on early PET scans 52 patients revealed a pathologic lesion compatible with LR (median SUV_{max}: 5.9; range: 2.9 - 17.6) and in only 9 patients (4.2 %) an unclear finding was described. Early PET imaging led to a significant rise in the detection rate (p<0.001) and a significant reduction of equivocal findings (p<0.001). Tracer accumulation in the urinary bladder could be found in 63 patients on early PET scans (29.6 %). However, acquisition starting time of early PET scans without urinary bladder activity was significantly lower in comparison to patients with urinary bladder activity already present (median starting time of 261 vs. 321 sec p.i.; range: 215-311 sec p.i. vs. 281-491; p<0.001). Median SUV_{max} value of lesions suggestive of LR on early images was significantly higher in comparison to gluteal muscle, inguinal vessels and seminal vesicle/anastomosis (median SUV_{max}: 5.9 vs. 1.9, 4.0 and 2.4, respectively). **Conclusions:** Assessment of LR in prostate cancer patients with biochemical relapse referred to 68Ga-PSMA-11 PET/CT is improved by additional early PET imaging, enhancing the detection rate of LR and reducing equivocal findings significantly. Early PET scans should be acquired as early as 4-5 min after tracer injection in order to obviate tracer accumulation in the urinary bladder.

E-PW068

177Lutetium PSMA radioligand therapy in patients with metastatic castration resistant prostatic cancer; assessment of response, clinical evaluation, toxicity

H. R. RATHORE, 400026, G. Bhat, P. Aland, C. Kannor, C. Kale, A. Parab, P. Chaudhuri, V. Lele; Jaslok Hospital and Research center, Mumbai, INDIA.

Purpose: To evaluate the biochemical, clinical and radiological effectiveness of [177]Lutetium-PSMA-617-DKFZ radioligand therapy in patients with extensive metastatic castration resistant prostate carcinoma. **Subjects and Methods**: A total of 11 patients with biopsy proven carcinoma of prostate referred to Nuclear Medicine Department, Jaslok Hospital and Research Centre, Mumbai for 177-Lu-DKFZ-617-PSMA Radioligand Therapy. Patients underwent the scan and therapy abiding the standard protocol. Association of biochemical and clinical response to overall survival are assessed at pre therapy and post therapy at 2, 4, 6, and 10 weeks. Baseline assessment is done by correlation with WHO grade, Gleason's score, PSA level, Gallium PSMA PET Scan, EC renal scan. Clinical response by KPS and ECOG score. Bone Marrow toxicity and systemic toxicity by estimating CBC, LFT, RFT, electrolytes, ionised calcium, LDH, ALP by ECOG common toxicity criteria, CT-CAE. **Result:** All lesions detected by ^{68}Ga-HBED-CC PET-CT exhibited high 177-Lu-DKFZ-617-PSMA uptake on post therapy planar and SPECT images. 10 weeks after therapy 63.63% patients experienced PSA decline of which 18.18% experienced more than 50% PSA decline, 18.18% patients more than 30% PSA decline, 27.27% patients shows any PSA decline. 36.36% patients experienced rise in PSA out of which 27.27% experienced more than 30 % raise in PSA which shows no response to therapy, 9.09% experienced progressive disease. Relevant hematotoxicity (ECOG CTC and CTCAE) grade 3/4 anaemia in 18.18% and grade 1/2 in 27.27%, and grade 3/4 thrombocytopenia in 18.18 % and grade 1/2 leukopenia in 27.27% of patients is experienced. 27.27% with progressive disease experienced deranged LFT by grade 1/2. 9.09% has experienced grade 1 changes in RFT. There is fall in serum electrolytes as Hyponatremia - grade 3 / 4 in 18.18% and grade 2 in 9.09%. There is grade 4 raise in LDL seen in 9.09% patients, grade 3 raise in ALP in 18.18% and grade 1 in 27.27% patients, and low ionized calcium with grade 1 changes are seen in 27.27% of patients. According to fall in PSA and overall response evaluation result shows Positive response in 18.18% patients, stable disease in 45.45% patients, progressive disease in 9.09% patients and no response to therapy is seen in 27.27% patients. More than six months progression free survival is seen in 63.63% patients. **Discussion**: 177-Lu-DKFZ-617-PSMA is a novel and promising RLT for mCRPC. Our initial results indicate that radioligand therapy with 177-Lu-DKFZ-617-PSMA is safe, effective and have low side effect profile.

E-PW069

One-step kit-based radiolabeled ^{68}Ga-THP-PSMA for PET imaging of PSMA expression: Biodistribution and first clinical experience

S. Schmuck; Medizinische Hochschule Hannover, Hannover, GERMANY.

Aim: Several ^{68}Ga-labeled tracers have become available for clinical molecular imaging of PSMA expression at positron emission tomography (PET). However, the labeling process of these compounds is rather complex and time consuming, limiting the accessibility of these tracers. Recently, ^{68}Ga-trishydroxypyridinone (THP)-PSMA, a novel tracer that can be labeled in one step by reconstitution of a kit with unprocessed generator eluate, has been introduced for imaging of PSMA expression. The aim of this study was to evaluate the human biodistribution of ^{68}Ga-THP-PSMA in patients with biochemical recurrence of prostate cancer after radical prostatectomy. **Materials and Methods:** 25 men (age, 72.1±5.7 years) with elevated PSA levels (2.5±3.9 ng/ml) after radical prostatectomy underwent a whole-body PET/CT after injection of ^{68}Ga-THP-PSMA at 60 minutes post injection. The biodistribution of ^{68}Ga-THP-PSMA was analyzed by assessing physiologic uptake by assessment of standardized uptake values (SUVs) in fixed isocontour-threshold volumes-of-interest placed in various organs including the parotid glands, liver, spleen, kidneys, gluteal muscle, and the superior vena cava for blood-pool. Tracer excretion was measured in both bladder and the intestine (duodenum, jejunum, ileum, ascending colon). Pathologic uptake was quantified in metastases. **Results:** In humans, the physiologic uptake of ^{68}Ga-THP-PSMA is low in the parotid glands (SUV_{mean}, 4.0 ± 1.6 (1.6 - 8.4)), liver (SUV_{mean}, 1.3 ± 0.2 (0.8 - 1.7)), spleen (SUV_{mean}, 1.7 ± 0.4 (1.1 - 2.7)), blood-pool (SUV_{mean}, 1.4 ± 0.3 (0.8 - 2.0)), and background (gluteal muscle; SUV_{mean}, 0.3 ± 0.1 (0.2 - 0.5)). Intestinal tracer excretion was negligible, but intense urinary tracer excretion was observed (bladder; SUV_{mean}, 221.8 ± 71.8 (83.3 - 368.1)). Tracer uptake (SUV_{mean}) in lymph node metastases was 5.4 ± 4.0 (1.6 - 19.8), and 3.9 ± 3.1 (0.6 - 11.3) in bone metastases. The mean tumor to background ratio (TBR) of lymph node metastases was 27.8 ± 25.3 (5.8 - 127.4), and the mean TBR of bone metastases was 18.6 ± 14.6 (3.6 - 51.4). **Conclusion:** ^{68}Ga-THP-PSMA offers a favorable biodistribution with low physiologic uptake in organs, blood-pool and background. Tracer uptake in pathologic lesions is associated with satisfying TBRs. There is marked urinary activity. Negligible intestinal tracer excretion allows for clear visualization of retroperitoneum and abdomen.

[18]F-Organotrifluoroborate Probes Targeting PSMA for PET Imaging of Prostate Cancer: One-step Radiosynthesis, High Tumor Uptake and High T:NT Ratios

M. L. Lepage[1], H. Kuo[2], H. Merkens[2], N. Colpo[2], F. Bénard[2], K. Lin[2], D. M. Perrin[1]; [1]University of British Columbia, Vancouver, BC, CANADA, [2]BC Cancer Research Centre, Vancouver, BC, CANADA.

Objectives: The past decade has seen the development of many PET radiotracers targeting the Prostate-Specific Membrane Antigen (PSMA) for prostate cancer (PCa) imaging, including metal chelation or ^{18}F-radiofluorination. Given the great interest in imaging PSMA for PCa diagnosis, a rapid, one-step, user-friendly, aqueous fluorination reaction that can be applied to PSMA-ligands would be of great utility. Moreover, excellent images, defined by high tumor uptake values and high T:NT ra-

tios would be equally essential to advance such a tracer to clinical applications. Organotrifluoroborates, as prosthetics afford very efficient, kit-like, one-step ^{18}F-labeling by isotope exchange (IEX). Here we have used this approach to prepare trifluroroborate derivatives of the Glu-Lys diureido scaffold to combine the advantages of one-step aqeous labeling with the production of a PSMA-specific tracer with excellent tumor images. **Methods**: To the core Glu-ureido-Lys was conjugated 2-naphthylalanine and then (4-(aminomethyl)cyclohexanecarboxylic acid) using standard SPPS. Azidoacetic acid was coupled to the N-terminus and reacted with a propargyl-pyridyl-trifluforoborate to yield a new conjugate containing a novel trifluoroborate prosthetic group. Labeling proceeded as previously reported where approximately 100 nmol of conjugate was reacted with ~1Ci of NCA ^{18}F-fluoride. PET imaging and biodistribution studies were conducted in mice bearing PSMA-expressing LNCap prostate cancer xenografts. **Results**: This new ^{18}F-RBF$_3$-Glu-ureido-Lys conjugate was labeled in yields of 10-15%, at specific activities of >104 GBq/μmol. PET imaging and correlated ex-vivo biodistribution show substantial clearance to bladder with high tumor uptake (25±8 %ID/g) along with typically high kidney uptake (81±31 %ID/g). Excellent T:Bone (35±27), T:Muscle (145±57) and T:Blood (19±8) ratios were observed. Blocking by co-injection with DCFPyL (0.5 mg) reduced >95% uptake demonstrating specific uptake by PSMA. **Conclusions**: Here we show several salient points: 1) IEX on organotrifluoroborates afford the simplicity of a one-step labeling without pre-drying of the ^{18}F-fluoride; 2) Radiosynthesis proceeds in a clinical setting within a fully shielded hot-cell within 30 min or less in reasonable yields and high specific activities; 3) Purification involves a simple Sep-Pak elution 4) Images show excellent tumor uptake values and exceptionally high T:M and T:B ratios, values that compare favorably to or exceed those seen with ^{18}F-DCFPyL. These data suggest that this compound or a closely related analog will be suitable for human clinical applications.

2-deoxy-glucose is a Respiratory Substrate for Endoplasmic Reticulum of Murine Breast Carcinoma Cells: New View on PET-Imaging

V. Cossu[1], S. Ravera[2], S. Bruno[3], A. Orengo[1], A. Buschiazzo[4], A. Bellini[4], F. Grillo[5], M. Bauckneht[4], M. Piana[6], C. Ghersi[1], S. Morbelli[1], C. Marini[1,7], G. Sambuceti[1,4]; [1]Nuclear Medicine Unit, IRCCS AOU San Martino-IST, Genoa, ITALY, [2]Pharmacy Department, Biochemistry Laboratory, University of Genoa, Genoa, ITALY, [3]Department of Experimental Medicine, University of Genoa, Genoa, ITALY, [4]Nuclear Medicine Unit, Department of Health Sciences, University of Genoa, Genoa, ITALY, [5]Pathology Unit, IRCCS AOU San Martino-IST, Genoa, ITALY, [6]Department of Mathematics, University of Genoa, Genoa, ITALY, [7]CNR Institute of Bioimages and Molecular Physiology, Milan, ITALY.

Introduction: The theoretical basis of ^{18}F-FDG imaging relies on the concept that, as 2-deoxy-glucose (2DG), it is trapped into the cell in its phosphorylated form. We previously documented that retention of ^{18}F-FDG and 2DG at least partially reflects the activity of an endoplasmic reticulum (ER) processing machin-

ery. This pathway is largely autonomous from the well-recognized cytosolic glycolysis and pentose phosphate pathway and is triggered by hexose-6-phosphate dehydrogenase (H6PD) whose catalytic activity recognizes both monosaccharides as substrates. Aim of this study was to verify whether ^{18}F-FDG and 2DG oxidation in the ER of cancer cells can contribute to explain the link between ^{18}F-FDG uptake and disease aggressiveness. **Subjects & Methods:** Murine breast carcinoma (4T1) cells were cultured in DMEM medium containing 11 mM glucose under standard conditions. Isolation of mitochondria and microsomes (ER) was performed by standard methods. In each cell fraction, oxygen consumption rate (OCR) was measured using an amperometric oxygen electrode while ATP synthesis was measured by the luciferin/luciferase chemiluminescence method. Response to 5 mM pyruvate + 2.5 malate (conventional substrates) or 0.7 mM NADH was tested. Similarly, response to 11 mM 2DG, glucose, glucose-6-phosphate (G6P) or galactose were tested in the presence of 0.2 mM NADP. Western blot (WB) and co-localization experiments were performed according to standard procedures. **Results:** Mitochondria conducted the oxidative phosphorylation (OXPHOS) metabolism only when stimulated with the pyruvate + malate, consuming 16.7±1.1 nmolO/min/mg and producing 24.7±2.1 nmolATP/min/mg. By contrast, microsomal fraction consumed oxygen and synthetized ATP (17.5±1.8 and 42.7±1.9 nmol/min/mg, respectively) in the presence of NADH, a substrate not suitable for mitochondria, documenting an extra-mitochondrial aerobic metabolism located in the ER. Interestingly, we observed the co-localization of subunit of the respiratory complex IV (COX1) with ER protein (calnexin). Moreover, in microsomal fraction, OXPHOS activity was present also after the addition of several hexoses and NADP, the substrates of H6PD. In particular, 2DG triggered a measurable microsomal OCR and ATP synthesis (64.1±2.2 and 182±12 nmol/min/mg, respectively), as well as glucose, G6P or galactose. This functional response well agreed with evidence of H6PD presence in microsomal fraction at WB. **Conclusion:** ER displays respiratory and ATP synthetic activities, triggered by H6PD and able to utilize 2DG as substrate. In cancer cells, the activity of this pathway is well represented and might contribute to the link between ^{18}F-FDG uptake and disease aggressiveness.

E-PW072

Assessment of pharmacokinetic properties of copper-64 and gallium-68 labelled NODAGANOC analogues for neuroendocrine tumours detection.

M. Asti[1], R. S. B. H. Schreuder[2], M. Iori[1], P. C. Capponi[1], S. Rubagotti[1], G. Cicoria[3], R. Zijlma[2], G. N. Doeswijk[4], M. De Jong[4], P. H. Elsinga[2], G. Luurtsema[2]; [1]Arcispedale Santa Maria Nuova-IRCCS, Reggio Emilia, ITALY, [2]University Medical Center Groningen, Groningen, NETHERLANDS, [3]S. Orsola-Malpighi University Hospital, Bologna, ITALY, [4]Erasmus Medical Center, Rotterdam, NETHERLANDS.

Background: Neuroendocrine tumors (NETs) are a heterogeneous group of neoplasms that can metastasize over the whole body. PET tracer ^{68}Ga-DOTATOC is frequently used in the diagnosis of NETs but the NODAGANOC analogue labelled with

gallium-68 or copper-64 might express superior features. In this study, the chemical characterization, the labelling properties and the *in vitro* behavior of ^{68}Ga and ^{64}Cu-NODAGANOC were explored and compared to those of ^{68}Ga-DOTATOC. **Methods:** Synthesis of non radioactive compounds was performed by incubating 300 µg NODAGANOC with 300 µL of 10% acetic acid and either 2 mg of copper(II) acetate or gallium(III) chloride for Cu-NODAGANOC or Ga-NODAGANOC, respectively. The crude mixture was purified by HPLC. Synthesis of radioactive compounds was performed starting from: i) ^{64}CuCl$_2$ (specific activity 420 GBq/umol) in HCl 0.1M, 74 MBq/mL solution ii) a 18 months old 1850 MBq ^{68}Ge/^{68}Ga generator (GalliaPharm, EZAG) eluted with 4 ml 0.1M HCl. 500 uL (i.e. 37 MBq copper-64 or 50 MBq gallium-68) was added to a solution containing various amounts of NODAGANOC (21, 10, 5, 3 nmol) in 1.5 M formate or acetate solution (pH: 3, 4, 5). The mixtures were heated at different temperatures (100, 50, RT °C) using various incubation times (15, 10, 7 min). Radiochemical purity (RCP) was assessed by UHPLC equipped with UV (set 220 nm) and radiochemical detector. Stability (saline and blood), lipophilicity and competitive binding were determined following published methods. **Results:** Cu-NODAGANOC and Ga-NODAGANOC were successfully synthesized and identified by LCMS-QTOF. Moreover, labeling of ^{68}Ga-NODAGANOC and ^{64}Cu-NODAGANOC was optimized and achieved a radiochemical yield (RCY) >99% and RCP >95%. Optimal radiochemical incorporation of copper-64 could be achieved at milder conditions than with gallium-68; copper-64 showed a RCY > 99% with 3 nmol of NODAGANOC for 7 minutes at RT. For gallium-68 the mildest conditions to obtain RCY >99% were 5 nmol NODAGANOC; 7 minutes at 75°C. Both radiopharmaceuticals showed high stability in plasma *in vitro* (>94 %, 2 h) and comparable lipophilicity (-1.14 and -1.63, respectively). The computed IC50 for both tracers was 0.2 nM and comparable with that of ^{68}Ga-DOTATOC. **Conclusions:** Both ^{68}Ga and ^{64}Cu-NODAGANOC appear promising radiotracers for detection of NETs tumours. Future studies are needed to assess whether ^{68}Ga and ^{64}Cu-NODAGANOC are superior to ^{68}Ga-DOTATOC in clinical practice.

E-PW073

^{18}F-FLT PET/CT imaging and inhibition of multiple signaling pathways downstream EGFR and MET receptors in resistant NSCLC

F. Iommelli[1], V. De Rosa[1], M. Monti[2], C. Terlizzi[2], M. Panico[1], S. Del Vecchio[2,1]; [1]Institute of Biostructures and Bioimaging, National Research Council, Naples, ITALY, [2]Department of Advanced Biomedical Sciences, University "Federico II", Naples, ITALY.

Aim: Simultaneous targeting of EGFR and MET receptors with a combination of selective tyrosine kinase inhibitors (TKIs) in patients with non-small cell lung cancer (NSCLC) is a strategy currently tested in clinical trials to prevent the emergence of pre-existing resistant clones in response to drug pressure, to overcome acquired MET-mediated resistance in EGFR-driven NSCLC and to exploit a synergistic effect improving clinical outcome. We previously reported that imaging with ^{18}F-FLT PET/

CT is able to detect reversal of MET-mediated resistance and to reveal synergy among different TKIs in the treatment of NSCLC. To elucidate the mechanisms responsible for the improvement of tumor response to combination therapy, we tested whether inhibition of multiple signaling pathways may converge on a common downstream effector to modulate cell proliferation. **Methods:** NSCLC cells with MET amplification and wild type EGFR (H1993) were treated with erlotinib and crizotinib, either alone or in combination and then tested for cell viability and levels of p-STAT3 (Tyr705)/STAT3, pAKT/AKT, pERK/ERK, cyclin D1 and c-Myc. Furthermore, H1993 tumor-bearing mice underwent ^{18}F-FLT PET/CT scan before and after treatment with escalating doses of EGFR and MET inhibitors, alone or in combination, and post-treatment changes of ^{18}F-FLT uptake in tumors were determined. At the end of imaging studies, tumors were removed and western blotting analysis of signaling mediators and effectors was performed on tumor lysates. Synergistic effect was evaluated for in vivo and in vitro data sets by determining the combination index (CI) using the CompuSyn software. **Results:** Imaging studies showed a significant reduction of ^{18}F-FLT uptake in response to combined treatment with escalating doses of EGFR and MET inhibitors that was higher than that obtained with treatment with single agents. In H1993 cells and excised tumors, combined treatment with EGFR and MET inhibitors caused a cumulative dose-dependent reduction of p-AKT, p-ERK and cyclin D1 levels that was stronger than that obtained by each drug alone. A synergistic effect among the two TKIs was also observed in the reduction of p-STAT3 (Tyr705) and c-Myc levels at late time points (48h-72h) in both H19993 cells and excised tumors. **Conclusion:** Our findings indicate that synergy between EGFR and MET inhibitors in determining targeted growth arrest and hence reduction of ^{18}F-FLT uptake may occur through the inhibition of multiple signaling pathways and the suppression of feedback activation of STAT3 and c-Myc which provide a compensatory cellular mechanism to escape drug injury.

E-PW074

New Sensitive Method For HEPES Quantification in [^{68}Ga]-Radiopharmaceuticals

I. F. Antunes[1], G. M. Franssen[2], R. Zijlma[1], G. L. K. van der Woude[1], C. B. Yim[3], P. Laverman[2], H. H. Boersma[1], P. H. Elsinga[1]; [1]University Medical Center of Groningen, Groningen, NETHERLANDS, [2]Radboud University Medical Center, Nijmegen, NETHERLANDS, [3]University of Turku, Turku, FINLAND.

Objective: The introduction of a GMP-certified [^{68}Ga]-generator spurred the application of [^{68}Ga]-radiopharmaceuticals. Some radiosyntheses of [^{68}Ga]-radiopharmaceuticals are more efficient and stable when performed with HEPES buffer[1,2] which is an impurity. Thus, prior to clinical use, quality control (QC) must be conducted to ensure that HEPES does not exceed the maximum dose of 200 µg/V$_{Injected}$ as described in *European Pharmacopoeia*[3]. Here we compared the TLC-method[3] with a new HPLC-method to quantify HEPES in [^{68}Ga]-radiopharmaceuticals. In addition, samples from different institutes were compared to

evaluate whether the synthesis of different [68Ga]-radiopharmaceuticals or the use of different synthesis modules could affect the amounts of HEPES. **Method:** The TLC-method was performed as described in the literature[3] with additional iodine incubation times (4, 30, 150 min and 18 h). The HPLC method (XBridge C18 column; mobile phase: ammonium formate 20mM) was validated according to ICH-M3 guidelines. Various HEPES concentrations (6-2000 μg/mL) were analysed by both methods. Samples of [68Ga]DOTATOC (n=9), [68Ga]HBED-CC-PSMA (n=8) and [68Ga]NODAGA-Exendin (n=9) from different institutes were tested with the HPLC method. **Results:** HEPES was not detected by the TLC method within 4 min incubation in an iodine saturated chamber. At 18 h, spots were only visible > 50 μg/mL. The HPLC method had a limit-of-quantification of 3 μg/mL and a limit-of-detection of 1 μg/mL. The HEPES concentrations in the final products of [68Ga]DOTATOC, [68Ga]PSMA and [68Ga]Exendin were 20±7 μg/mL, 5±6 μg/mL and 42±14 μg/mL, respectively. No significant differences were observed in the amounts of HEPES present in the same [68Ga]-radiopharmaceutical produced with similar protocols and synthesis modules, even when coming from different institutes. However, the HEPES concentration was affected when produced with a different synthesis module with different labelling reaction conditions. **Conclusion:** The TLC method described in *European Pharmacopoeia* is not sufficiently sensitive and thus unsuitable to use prior to QC release. The HPLC method was sensitive, quantitative, reproducible and suitable for QC release. With this method we were able to determine that the labelling reaction conditions may affect the amounts of HEPES in the final product. This new analytical system will be used for further studies in order to reduce the amounts of HEPES in the final product. **Acknowledgements:** This study was funded by the BetaCure project 666495. **References:** 1. Effect of Selective Endothelin B Receptor Agonist IRL-1620 on [18F]FDG Uptake in a Mouse Model of Breast Cancer

*A. Yatsyna, O. Sarrhini, M. Bentourkia, R. Lecomte, **S. V. Selivanova**; Sherbrooke Molecular Imaging Centre, CRCHUS, Université de Sherbrooke, Sherbrooke, QC, CANADA.*

Aim: Activation of endothelin type B (ET$_B$) receptors on the vasculature can produce a vasodilation or vasoconstriction of varying degrees of potency and this response depends on the cell type and tissue. ET$_B$ receptors on endothelial cells produce vasodilation, while those on vascular smooth muscle cells produce vasoconstriction. Often, tumor-associated blood vessels lack smooth muscle cells that control blood flow at normal conditions and cannot provide required auto-regulation. It was shown previously that ET$_B$ receptor agonists can produce transient effects on tumor vasculature. Consequently, ET$_B$ ligands were proposed as tools to selectively modify tumor blood flow for enhanced drug delivery. The purpose of this study was to

evaluate the effect of selective ET$_B$ agonist, IRL-1620, on [18F]FDG uptake in different organs and tissues in a mouse animal model of breast cancer. **Methods:** BALB/c mice were inoculated with MC7-L1 mouse mammary carcinoma cells and tumors were allowed to grow. Acute inflammation was induced with turpentine oil. Mice were injected with either, phosphate buffered saline or IRL-1620 (Suc-Asp-Glu-Glu-Ala-Val-Tyr-Phe-Ala-His-Leu-Asp-Ile-Ile-Trp) followed by [18F]FDG. Tissue distribution of [18F]FDG was monitored using PET and the radioactivity uptake in tumor, inflammation, muscle and other organs of interest was quantified. *Ex vivo* biodistribution (60 min after [18F]FDG injection) and histological staining were performed to validate the results. Two animals were subjected to a continuous infusion of [18F]FDG while IRL-1620 was administered to observe its effect in real time. **Results:** In PET, [18F]FDG uptake in tumor increased by ~50% on average when [18F]FDG was administered 15 minutes after the treatment with IRL-1620; tumor-to-muscle ratio rose by ~30%. Tumor-to-inflammation ratio showed negative correlation with the progression of inflammation, with or without IRL-1620. Results of *ex vivo* biodistribution revealed similar trend: while tumor uptake of [18F]FDG has substantially improved with IRL-1620 administration, the uptake in inflamed tissue depended more on the degree of acute inflammation. In infusion experiments, the rate of [18F]FDG uptake increased 1.6 and 1.8 fold potentiated by IRL-1620. **Conclusions:** IRL-1620 significantly enhanced [18F]FDG uptake in the tumors of mice bearing mammary carcinoma allografts. [18F]FDG uptake in the inflamed tissue was dependent on the degree of acute inflammation. Effect of IRL-1620 on normal tissues and organs was much less pronounced. Administration of IRL-1620 together with [18F]FDG could be a promising strategy to improve the delivery of [18F]FDG to breast cancer lesions.

E-PW076

Prediction of the synergistic efficacy of capecitabine and TAS-102 in mice with colon cnacer xenografts using [18F] fluorothymidine positron emission tomography

S. Kim[1], J. JUNG[1], H. Lee[1], H. Soh[1], S. Lee[2], S. Oh[2], S. Chae[2], J. Lee[3], S. Lee[4], Y. Hong[5], T. Kim[5], D. Moon[2]; [1]Asan Institute for Life Sciences, Asan Medical Center, Seoul, KOREA, REPUBLIC OF, [2]Department of Nuclear Medicine, Asan Medical Center, Seoul, KOREA, REPUBLIC OF, [3]Department of Nuclear Medicine, Dankook University Hospital, Cheonan, KOREA, REPUBLIC OF, [4]Department of Pharmacology, Chungnam National University College of Pharmacy, Daejeon, KOREA, REPUBLIC OF, [5]Department of Oncology, Asan Medical Center, Seoul, KOREA, REPUBLIC OF.

Purpose: We investigated whether sequential combination therapy of capecitabine and trifluridine-tipiracil (TAS-102) could synergistically enhance antitumor efficacy in colon cancer xenograft models. We also examined 3'-deoxy-3'-[18F]fluorothymidine ([18F]FLT) positron emission tomography (PET) for prediction of the therapeutic response to a sequential combination of capecitabine and TAS-102. **Subjects & Methods:** [3H]FLT uptake, [3H]-S-(p-nitrobenzyl)-6-thioinosine binding, and thymidine kinase 1 activity after 5-fluorouracil treatment *in vitro* and

[18F]FLT uptake after capecitabine (360 mg/kg/day) in athymic nude mice (Balb/c-nu) with xenografts (n = 10-12 per group) were measured using eight human colon cancer cell lines HCT8, HT29, SW620, DLD-1, RKO, COLO205, HCT116, and LOVO. The synergistic effect of sequential combinations of 5-fluorouracil and trifluridine *in vitro*, and the sequential combination of oral capecitabine (30-360 mg/kg) and TAS-102 (trifluridine 75 or 150 mg/kg with tipiracil) in six xenograft models (n = 6-10 per group) was determined. **Results:** There were significant increases in [3H]FLT uptake in all cell lines ($P < 0.05$). Likewise, equilibrative nucleoside transporter 1 increased remarkably after 5-fluorouracil treatment in most cell lines ($P < 0.05$), except for DLD-1. Thymidine kinase 1 activity was also significantly increased in five cell lines after 5-fluorouracil treatment ($P < 0.05$), but not in the HCT8, SW620 and LOVO cell lines. Serial [18F]FLT PET images after capecitabine treatment revealed a significant increase in [18F]FLT uptake ([18F]FLT flare) in five xenograft models (HT29, RKO, COLO205, HCT116 and LOVO), but not in HCT8, SW620, and DLD-1 xenografts. [18F]FLT flare after capecitabine followed by extinction of flare activity had a strong correlation with tumor growth inhibition ($\rho = -0.81$, $P = 0.02$). The effects of the combination of 5-fluorouracil and trifluridine *in vitro* were synergistic in all cell lines. Of these capecitabine-resistant HCT8, HT29, SW620, and DLD-1 xenografts, only the HT29, which had a significant [18F]FLT flare after capecitabine, showed synergistic efficacy with a percent tumor growth inhibition of 51.1%. Capecitabine-sensitive HCT116 and LOVO xenografts, which had a significant [18F]FLT flare after capecitabine, also showed synergistic antitumor efficacy of low dose capecitabine and TAS-102. **Conclusion:** The sequential combination of capecitabine and TAS-102 is synergistic in tumors with an activated salvage pathway after capecitabine in mice. [18F]FLT PET imaging may predict the response to capecitabine and the synergistic antitumor efficacy of a sequential combination of capecitabine and TAS-102.

E-PW077

[18F]-5-fluoroaminosuberic acid ([18F]FASu) superior to [18F]FDG in small animal PET/CT imaging of human xenografts

M. Colovic[1,2], H. Yang[1], H. Merkens[2], L. Southcott[1], N. Colpo[2], J. Rousseau[2], F. Benard[2,3], P. Schaffer[1,3]; [1]TRIUMF, Vancouver, BC, CANADA, [2]British Columbia Cancer Research Centre, Vancouver, BC, CANADA, [3]Department of Radiology, University of British Columbia, Vancouver, BC, CANADA.

Aim: [18F]fluorodeoxyglucose ([18F]FDG) is the most widely-used positron emission tomography (PET) tracer. The sensitivity of [18F]FDG to detect cancer varies depending on the tumour type, and is lower in organs with high background activity, such as the brain. [18F]-5-fluoroaminosuberic acid ([18F]FASu) was recently characterized as an oxidative stress imaging agent targeting a cystine transporter protein, system x_C^-. The aim of this study is to compare [18F]FASu with [18F]FDG in imaging non-small cell lung cancer and glioma xenografts in mice. **Materials and Methods:** A series of human cancer cells lines was used in this study, including a non-small cell lung cancer cell line, A549, and glio-

blastoma cell line, U-87. *In vitro* [18F]FASu uptake was measured at 20, 40 and 60 min time points, in the presence or absence of system x_C^- inhibitor sulfasalazine. For biodistribution and *in vivo* imaging studies, immunocompromised Rag2M female mice were inoculated subcutaneously with either A549 or U-87 cells in 1:1 ratio with Matrigel. Once tumours reached ~7-10 mm in diameter, mice were intravenously injected with [18F]FASu or [18F]FDG. Mice destined for biodistribution were sacrificed by CO_2 asphyxiation 60 min after radiotracer injection; their organs were harvested and measured on a PerkinElmer Wizard gamma counter. Mice destined for imaging were scanned on a Siemens Inveon Multimodality PET/CT System at 60 min post-injection, and subsequently sacrificed as described above. **Results:** [18F]FASu showed variable *in vitro* uptake in the tested cell lines, ranging from 1.84 % for MDA-MB-231 TNBC cell line, up to 11.88 % uptake/mg protein for A549 cells at 60 min. The tracer uptake increased over time, and was efficiently blocked with addition of sulfasalazine, demonstrating system x_C^-- specific uptake. We then selected the cells lines among the lowest (U-87) and highest (A549) *in vitro* uptake, for subsequent animal studies. [18F]FASu had higher tumour uptake *in vivo* than [18F]FDG, with 4.96 compared to 3.75 %ID/g for U-87 tumours, and 5.00 *versus* 2.33 %ID/g for A549 tumours, which was also evident on the PET/CT images. **Conclusion:** In murine models, [18F]FASu can be used to clearly visualize non-small cell lung cancer and glioblastoma xenografts *in vivo* better than [18F]FDG. With significantly lower background uptake, image contrast was superior to [18F]FDG. Particularly, low brain uptake of [18F]FASu highlights its potential for imaging intracranial malignancies.

E-PW078

Imaging Cancer Metastases in a Metastatic Pancreatic Ductal Adenocarcinoma (PDAC) Rodent Model Using (4S)-4-(3-18F-fluoropropyl)-L-Glutamate (FSPG) by Small-Animal PET/CT: a Preclinical Study

M. CHENG[1], Y. Huang[1], L. Hsin[2], C. Shiue[3], Y. Chang[1], R. Yen[1], Y. Tien[1]; [1]National Taiwan Universty Hospital, Taipei, TAIWAN, [2]School of Pharmacy, Molecular Imaging Center, and Center for Innovative Therapeutics Discovery, National Taiwan University, Taipei, TAIWAN, [3]National Taiwan University Hospital and Molecular Imaging Center, Taipei, TAIWAN.

Background and Aim: The System xC- transporter (xCT) mediates the sodium-independent cellular uptake of cysteine in exchange for intracellular glutamate, a pathway involved in the antioxidation process. Cancer cells show survival advantage over normal cells by higher expression of xCT. In humans, xCT is found to express in the brain, pancreas, stromal, and immune cells. FSPG is a new PET tracer reflecting cellular xCT activity. Human studies have shown intense physiologic distribution of FSPG in the pancreas. We hypothesize that xCT activity in the pancreas is upregulated during malignant transformation, which makes FSPG an ideal tracer to detect PDAC metastases. Accurate staging is of utmost importance in patients with PDAC before undergoing surgery. Here we report the result of a preclinical study comparing tumor detection rate of FSPG, com-

paring to FDG, in a metastatic PDAC rodent model. **Materials and Methods:** *In vivo* metastatic PDAC model was constructed by orthotopically injecting pancreatic cell lines (5 x 10^5 cancer cells) labeled with luciferase gene into pancreas of the SCID mice (*n*=6). FDG and FSPG small-animal PET scanning were performed in the same mouse within 1 day apart weekly for at least 2 weeks. In vivo bioluminescence imaging using the IVIS Spectrum was also done on the 2nd day after completing the dual tracer imaging. We then compared the efficiency of tumor detection between FSPG and FDG PET. **Results:** FSPG detected hepatic and peritoneal metastases from PDAC at an earlier time than FDG PET/CT. Besides, FSPG could detect more lesions at an advanced stage of cancer compared to FDG. Superior imaging characteristics of FSPG compared to FDG was also found. The tumor to nontumor ratio was 2.94±1.12 for FDG and 4.77±1.59 for FSPG. **Conclusion:** Our preliminary results suggest FSPG may be a useful PET imaging tracer in PDAC patients before undergoing surgery. Further studies in patients with PDAC are needed.

E-PW079

Potential of PET imaging to monitor upregulation of NET-1 transporter

S. M. Turnock[1], D. R. Turton[1], D. M. Ciobota[1], O. Yogev[1], L. Chesler[1], T. Wilson[2], V. Gouverneur[2], G. Smith[1], G. Kramer-Marek[1]; [1]The Institute of Cancer Research, Sutton, UNITED KINGDOM, [2]University of Oxford, Oxford, UNITED KINGDOM.

Aims: The norepinephrine analogue ^{123}I-mIBG (*meta*-iodobenzylguanadine) is widely used in diagnostic imaging of NET-1 expressing cancers such as neuroblastoma (NB). However, it is not sensitive enough to accurately assess tumour response rates to high doses of ^{131}I-mIBG in high-risk NB patients. Therefore, we have investigated the potential of ^{18}F-mFBG (*meta*-fluorobenzylguanidine) to improve imaging of NB using Positron Emission Tomography (PET) and to guide therapeutic combinations with ^{131}I-mIBG that could reduce dose and therefore toxicity, and increase efficacy by upregulating expression and/or function of the NET-1 transporter. **Materials and Methods:** ^{18}F-mFBG was radiolabelled using a recently developed copper catalysed nucleophilic fluorination from a borylated precursor. The specificity of ^{18}F-mFBG to NET-1 was analysed in a panel of NB cell lines with varying NET-1 expression levels via cell uptake assay and compared with ^{123}I-mIBG. The specificity of the radiotracer *in vivo* was evaluated in mice bearing SK-N-BE(2)C (NET-1+ve) and Kelly (NET-1-ve) subcutaneous xenografts. PET/CT images were acquired at 1 and 4 h p.i. to determine systemic radiotracer distribution. The results were compared with the distribution of ^{123}I-mIBG. At the conclusion of each imaging session, blood and major organs were collected and radioactivity accumulation measured using a γ-counter. *Ex vivo* analysis of NET-1 expression was assessed by Western blot (WB) and immunohistochemistry (IHC). To modulate ^{18}F-mFBG tumour uptake, proof of concept *in vitro* studies were done using the mTORC1/2 inhibitor, AZD2014. Upregulation of NET-1 was measured by WB, ^{18}F-mFBG and the fluorescent neurotransmission transporter cell uptake assays. **Results:** ^{18}F-mFBG uptake correlated *in vitro* with NET-1 expression in a panel of NB

cell lines and was in concordance with the results obtained for ^{123}I-mIBG. Moreover, there was also increased and dose dependent uptake of ^{18}F-mFBG in response to AZD2014. *In vivo* studies demonstrated that ^{18}F-mFBG can differentiate between NET-1 expressing (SK-N-BE(2)C) and non-expressing (Kelly) tumours at 4 h p.i. (3.58±1.40%ID/g vs. 1.25±0.14%ID/g, respectively). Tracer was eliminated quickly from the blood and normal tissues, allowing high contrast images to be acquired 4 h p.i. (T:B 6.94±1.44; T:M 2.37±0.80). A strong correlation was observed between *ex vivo* estimates of tracer concentration and the transporter expression measured in the tumour tissues (IHC, WB). **Conclusion**: ^{18}F-mFBG can quantifiably assess different levels of NET-1 transporter *in vitro* and *in vivo* therefore might provide guidance for novel therapy plans and allow for the rapid identification of responders and non-responders in future clinical trials.

Early response evaluation by ^{18}F-FDG-PET influences management in gastrointestinal stromal tumor patients treated with neo-adjuvant intent

S. Farag[1], N. Steeghs[1], W. T. van der Graaf[2,3], F. van Coevorden[1], D. J. Grunhagen[4], A. K. L. Reyners[5], P. A. Boonstra[5], H. J. Gelderblom[6], L. de Geus-Oei[6,7]; [1]Antoni van Leeuwenhoek Hospital, Amsterdam, NETHERLANDS, [2]The Radboud University Medical Center, Nijmegen, NETHERLANDS, [3]Institute of Cancer Research, London, UNITED KINGDOM, [4]Erasmus Medical Center - Cancer Institute, Rotterdam, NETHERLANDS, [5]University of Groningen, Medical Center Groningen, Groningen, NETHERLANDS, [6]Leiden University Medical Center, Leiden, NETHERLANDS, [7]University of Twente, MIRA Institute, Twente, NETHERLANDS.

Background: Early response evaluation by ^{18}F-fluorodeoxyglucose (FDG) positron emission tomography (PET) is effective in gastrointestinal stromal tumors (GISTs) treated with imatinib and recommended in GISTs treated with neo-adjuvant intent. Yet, it is unclear whether this effects treatment decisions. **Methods:** All patients in the Dutch GIST Registry treated with imatinib with neo-adjuvant intent were identified. Only FDG-PETs made within 8 weeks after initiation *or change* (in dose or switch) of imatinib were included. Responses were derived from radiological reports and defined in 3 categories: 1) complete response; 2) partial response; 3) no response. Change in management was defined as a difference between pre-PET and post-PET treatment plans. Four categories were defined: change in 1) surgical management; 2) systemic treatment; 3) treatment objective (from curative to palliative); 4) management regarding a second tumor. **Results:** Seventy FDG-PETs for early response evaluation in 63 patients treated with neo-adjuvant intent were identified. Forty-one patients (65.1%) had a KIT exon 11 and 22 (34.9%) had a non-KIT exon 11 mutation (15 other and 7 unknown mu-

tations). Of the 70 scans 64 (87.1%) had a baseline, 50 (71.5%) showed metabolic response (partial and complete), and 18 (25.7%) led to change in management. Change in management was strongly correlated with a lack of response (p<0.001) and a non-KIT exon 11 mutation (p<0.001). Mutational status and response were strongly correlated (p<0.001). Out of 29 FDG-PETs conducted in non-KIT exon 11 GISTs, 15 (51.7%) led to change in management: 1 (3.4%) in surgical management, 6 (20.7%) in systemic treatment, 7 (24.1%) in both and 1 (3.4%) regarding a second tumor . Out of 51 FDG-PETs conducted in KIT exon 11 GISTs, change in management was seen 3 times (5.9%): twice in systemic treatment (dose increase after partial response was seen) and once regarding a second tumor. No change in treatment objective was seen. **Conclusion:** In contrast to GIST patients harboring a KIT exon 11 mutation, in non-KIT exon 11 mutated GISTs treated with neoadjuvant intent early response evaluation by FDG-PET often leads to change in management.

E-PW081

The prognostic significance of metabolic tumor volume (MTV) and total lesion glycolysis (TLG) with F18 FDG PET / CT in non-small cell lung cancer (NSCLC)

S. Göksel, Y. Yürekli, A. Cengiz; Adnan Menderes University Medical School Department of Nuclear Medicine, Aydın, TURKEY.

Purpose: To investigate the relationship between the semi-quantitative parameters such as SUVmax, MTV and TLG and the stage of disease and histological subtype and contribution of these parameters to prediction of prognosis in NSCLC. **Subjects and Methods:** A total of 102 patients (40-89 years old) with the diagnosis of NSCLC and underwent PET/CT imaging for staging were included in the study. Histopathological diagnosis, stage of the disease, SUVmax-MTV-TLG values of mass lesions and date of diagnosis were recorded. Survival times of the patients were determined by phone calls to all patients. Mann-Whitney U test was used for statistical comparisons between the groups. The relationship between survival time and MTV, TLG, SUVmax was determined by Spearman correlation analysis. The relationship between survival time and TNM stages was determined by the Kaplan-Meier test. **Results:** 71 patients had a pathological diagnosis of squamous cell carcinoma (69.61%) and 31 patients had adenocarcinoma (30.39%). In surviving patients (27.45%) the mean MTV value was 50.21 ± 57.32, the mean TLG value was 481.02 ± 581.87, and the mean SUVmax value was 16.70 ± 8.45. In deceased patients (72.54%), the mean MTV value was 68.28 ± 75.89, the mean TLG value was 553.09 ± 662.97 and the mean SUVmax value was 14.35 ± 5.85. When the relationship between TNM stage of the disease and survival was examined, survival times were shorter in patients with advanced stage (p: 0.002). Statistically significant negative correlation was determined between MTV and survival (p: 0.020) and TLG and survival (p: 0.027). No statistically significant relationships between SUVmax and survival (p: 0.861) and SUVmax and stage of the disease (p: 0.473) have been determined. Mean MTV value was 22.32 in stage 1,2 and 68.2 in stage 3,4 (p: 0.012); The mean TLG value was calculated as 232.27 in stage 1,2 and 569.69 (p: 0.037) in stage 3,4. As the stage increased, MTV and TLG increased and survival time decreased. There was no significant relationship between the MTV and TLG and histopathological types of the lesions. SUVmax values were higher in squamous cell carcinoma (p: 0.012). **Conclusion:** MTV and TLG of FDG PET/CT contribute significantly in predicting survival and prognosis in non-small cell lung cancers independently from stage and histopathological subtype.

E-PW082

Prediction of small early lung adenocarcinoma with aggressive histopathologic subtypes using PET and CT radiomic features

C. Liu, W. Choi, S. Riyahi, W. Lu, J. Oh, J. Deasy, P. Adusumilli, W. Weber; Memorial Sloan-Kettering Cancer Center, New York City, NY, UNITED STATES OF AMERICA.

Purpose: The solid and micropapillary (MIP) histopathologic patterns have been identified as indicators for poor prognosis of patients with small early lung adenocarcinoma (ADC). Patients with these aggressive subtypes may benefit from lobectomy rather than limited resection of the tumors. This study was aimed to classify early small lung ADC with these aggressive components by using positron emission tomography (PET) and computed tomography (CT) radiomic analysis. **Materials and Methods:** The study retrospectively included 135 patients with stage I lung adenocarcinoma with tumor size smaller than 2cm. Preoperative diagnostic CT and 18F-fluorodeoxyglucose (FDG) PET were analyzed. Tumor segmentation of CT was manually contoured on axial images. A semiautomatic algorithm using two standard deviations (SD) above background FDG uptake was applied for tumor segmentation on PET images. A total 170 of radiomic features was extracted from both diagnostic CT and PET, including intensity, shape, intensity-weighted shape, and texture features. The features were used to identify the cases with aggressive subtypes, which were defined as tumors with predominant solid or MIP components according to IASLC/ATS/ERS classification. Univariate analysis was performed to evaluate each radiomic feature using area under the curve (AUC) of receiver operating characteristic (ROC) and *p*-value computed by Wilcoxon rank-sum test. For multivariate analysis, important and non-redundant features were selected by class separability feature selection (CSFS) method using between-class and within-class scatter-matrix. The prediction model was then generated by least absolute shrinkage and selection operator (LASSO) regression. A 10-fold cross-validation was repeated ten times to obtain an unbiased estimate of the model, which constructed and evaluated 100 different models. **Results:** Among 135 patients, 36 patients had aggressive subtypes (solid: 26, MIP: 10). Ninety-four features were significant (all *p*<0.05) in univariate analysis (AUC: 0.61~0.78), including 29 CT features and 65 PET features. The SD of entropy on PET and the mean of cluster shade on CT were selected in CSFS-LASSO model. The sensitivity, specificity, and accuracy of the model were 75.5±4.6%, 74.3±1.9%, and 74.6±2.3%, respectively. The AUC of the CSFS-LASSO model was 0.75±0.03 (p<0.001). **Conclusion:**

Both PET and CT radiomics features are potential biomarkers of aggressive lung ADC subtypes. The prediction model combined both imaging modalities could serve as a non-invasive classification tool for small lung ADC subtypes and provide additional information for surgery.

E-PW083

Total lesion glykolysis of the primary tumour as a biomarker derived from pre-operative FDG PET/CT outperforms established prognostic parameters in oral squamous cell carcinoma

D. Weidt[1], G. Spanier[2], T. Reichert[2], J. Meier[2], D. Hellwig[1], J. Grosse[1]; [1]*Department of Nuclear Medicine, University of Regensburg Medical School, 93059 Regensburg, GERMANY,* [2]*Department of Oral and Maxillofacial Surgery, University Hospital Regensburg, 93059 Regensburg, GERMANY.*

Objective: The purpose of this retrospective study was to investigate the impact of image derived biomarkers from FDG PET/CT prior to surgical resection in patients with initial diagnosis of oral squamous cell carcinoma (OSCC), namely maximum and mean tumoral SUV (SUVmax, SUVmean), metabolic tumour volume (MTV) and total lesion glycolysis (TLG) of the primary tumour to predict overall survival (OS). Furthermore to compare its prognostic value with established prognostic factors such as lymph node status and UICC stage. **Materials and Methods:** A total of 127 subsequent patients with biopsy-proven OSCC was included who underwent FDG PET/CT between 2006 and 2013 before surgery. The PET/CT acquisition (Biograph 16, Siemens, Germany) was started 60 min p.i. of 3 MBq FDG per kg body weight. SUVmax, SUVmean, MTV and TLG of the primary tumour were measured using ROVER (ABX, Radebeul, Germany). MTV was delineated with a relative threshold of 41% SUVmax. OS, defined as time from PET/CT until death of any cause, was estimated according to Kaplan-Meier and compared between median-splitted groups by the log-rank test. Prognostic parameters were analyzed by univariate and multivariate Cox regression. **Results:** During follow-up 52 (41%) of the patients died. All patients had a known status at 36 months after initial PET/CT. Median OS was longer for patients with lower MTV (≤5.3 mL: >95 months; >5.3 mL: 59 months; p=0.004) or lower TLG (≤38.7 g: 95 months; >38.7 g: 47 months; p<0.001). SUVmax and SUVmean failed to be significant predictors for OS (both p>0.05). Univariate Cox regression identified MTV (hazard ratio [HR]=2.260, p=0.005), TLG (HR=2.808, p=0.001), lymph node status (HR=2.234, p=0.005) and UICC stage (HR=2.095, p=0.021) as prognostic factors, but not sex, age>60 years, history of smoking or alcohol abuse and adjuvant treatment. By multivariate Cox regression MTV (HR=1.991, p=0.019) and TLG (HR=2.808, p=0.001) turned out to be independent prognostic factors for OS, even if tested against lymph node status and UICC stage, with TLG being completely independent. **Conclusion:** The pre-therapeutic FDG PET/CT parameters MTV and TLG in the primary tumour are prognostic for OS of patients with an initial diagnosis of OSCC. TLG is the strongest independent prognostic factor for OS and outperforms established prognostic parameters in OSCC.

E-PW084

Adaptive 18F-FDG-PET-guided reirradiation for recurrent and second primary head and neck cancer

J. Schatteman[1], D. Van Gestel[2], D. Berwouts[1], W. De Gersem[1], G. De Kerf[3], W. De Neve[1], B. De Ost[3], A. Olteanu[1], S. Rottey[1], T. Vercauteren[1], F. Duprez[1], I. Goethals[1]; [1]*Ghent University Hospital, Ghent, BELGIUM,* [2]*Jules Bordet Institute, Brussels, BELGIUM,* [3]*Antwerp University Hospital, Antwerp, BELGIUM.*

Purpose: To evaluate feasibility, disease control, survival and toxicity after adaptive ^{18}F-FDG-PET-guided radiotherapy (RT) in recurrent and second primary head and neck squamous cell carcinoma (HNSCC). **Subjects & Methods:** A multicenter non-randomized prospective trial investigated the feasibility of adaptive RT ± concomitant cetuximab in 10 patients with recurrent (n=5) and second primary (n=5) HNSCC. Patients were treated with static beam IMRT (n=6) or helical tomotherapy (n=4) with 3 treatment plans based on 1 pre- and 2 pertreatment PET/CT scans and consecutively delivered in 6 weeks. The range of dose painting was 66.0-85.0 Gy in the dose-painted tumoral volumes in 30 fractions with fraction doses of 2.2-3.5 Gy, 2.2-2.5 Gy and 2.2-2.5 Gy during fractions 1-10, 11-20 and 21-30, respectively. If multidisciplinary decision for concomitant cetuximab was taken, patients received a loading dose (400 mg/m^2) one week before start of RT, followed by weekly doses of 250 mg/m^2 up to 6 times concomitant to RT. The primary endpoint of the study was to achieve a 2-year grade >3 toxicity-free survival in ≥30% of patients. **Results:** Median dose of the initial RT was 67.6 Gy. Median time interval from initial RT to reirradiation was 6.3 years. Median follow-up time was only 5.2 months, reflecting the poor overall survival. One-year locoregional and distant control were 38% and 76%, respectively. Overall and disease-free survival at 1 year were 30% and 20%, respectively. No grade 4 or 5 acute toxicity was observed in any of the patients, except for arterial mucosal bleeding in one patient. Three months after RT, grade 4 dysphagia and mucosal wound healing problems were observed in 1/7 and 1/6 of the patients, respectively. Grade 5 toxicity (fatal bleeding) was seen in 2 patients, respectively at 3.8 and 4.1 months of follow-up. Late toxicity until 1 year of follow-up could only be assessed in 2 patients. Data on 2-year grade >3 toxicity-free survival is not yet available; however, since only 20% of patients are still alive, a 30% 2-year survival free of grade >3 toxicity will not be achieved. There was a significant difference in SUV$_{max}$ between the pretreatment and second pertreatment PET after fraction 18 (*p* = 0.01). No significant differences in RT treatment volumes were observed. **Conclusion:** Adaptive PET-guided reirradiation is feasible. However, the primary endpoint (to achieve a 2-year grade >3 toxicity-free survival in ≥30% of patients) could not be evaluated in this limited patient cohort with poor survival.

E-PW085

Recurrent germinal tumor carcinoma: clinical and prognostic value of FDG-PET/TC

P. Alongi[1], M. Picchio[2], F. Caobelli[3], M. Spallino[4], L. Gianolli[2], M. Midiri[1], L. Evangelista[5]; [1]*San Raffaele G.Giglio Institute, Cefalù,*

ITALY, [2]IRCSS San Raffaele Scientific Institute, Milano, ITALY, [3]Basel University Hospital, Basel, SWITZERLAND, [4]University of Milano-Bicocca, Milano, ITALY, [5]Veneto Institute of Oncology IOV - IRCCS, Padova, ITALY.

Background and Aim: The aim of this multicentre retrospective study was to evaluate the diagnostic accuracy, the impact on treatment decision and the prognostic value of [18]FDG PET/CT in patients with suspected recurrent GTC. **Materials and Methods**: 114 patients affected by GTC were evaluated. All underwent 18F-FDG PET/CT for suspected recurrent disease. Diagnostic performance of visually interpreted FDG-PET/CT was assessed using histology (17 patients), other diagnostic imaging modalities (i.e. ceCT in 89 patients and MRI in 15) and clinical follow-up (114 patients) as reference. Progression-free survival (PFS) and overall survival (OS) were computed by means of Kaplan-Meier survival analysis. The progression rate (Hazard Ratio-HR) was determined using univariate and multivariate Cox regression analysis by considering various clinical variables. **Results**: The suspicion of recurrent GTC was confirmed in 47/52 patients with pathological PET/CT findings (by histology in 18 patients and by other diagnostic imaging modalities/follow-up in 29). Sensitivity, specificity, PPV, NPV, accuracy, LR+, LR-, pre-test Odds-ratio and post-test Odds-ratio of [18]FDG PET/CT were 86,8%, 90,2%, 88,4%, 88,7%, and 88,6%, 8,85, 0,14, 0,85, 8,85 respectively. FDG-PET/CT significantly impacted the therapeutic management in 26 cases (23%). At 2 and 5-year follow-up, PFS was significantly longer in patients with a negative PET/CT scan (98% and 95% vs 48% and 38%, p<0.05). An unremarkable scan was also associated with a longer OS (98% vs 69% after 2 years and 95% vs 33% after 5 years, p<0.05). In case of a negative PET/CT, PFS and OS were significantly longer regardless of staging TNM. Conversely, a positive PET scan was associated with an increased risk of disease progression (HR=24.3, p<0.05). At univariate Cox regression analysis, progression risk further increased in case of advanced disease at diagnosis and rising HCGB or AFP values (HR=7.3 for STAGE III-PET+; HR=14.3 elevated HCGB-PET+; HR 10.7 elevated AFP-PET+); all p<0.05). Multivariate Cox regression analysis confirms the higher risk of disease progression for PET posivite scan (PET+ HR 21,5; 95%IC: 2,5-185; p=0,005) and advanced disease at TNM staging (TNM stage III HR= 4.6; 95%IC: 1.7-12; p=0,002). **Conclusion:** FDG-PET/CT has very good diagnostic performance in patients with suspected recurrent GTC and provided a change in treatment approach in 23% of patients. Furthermore, FDG PET/CT has an important prognostic value in assessing the rate of PFS and OS and to estimate risk of disease progression in this setting of patients.

E-PW086

Costeffectiveness of second line diagnostic investigation in patients included in DANTE trial

E. Lopci[1], E. Morenghi[1], D. Tanzi[1], S. Cavuto[2], F. Lutman[1], G. Chiesa[3], E. Vanni[1], A. Chiti[1], M. Alloisio[1], M. Infante[4]; [1]Istituto di Ricerca e Cura a Carattere Scientifico (IRCCS), Milano, ITALY, [2]IRCCS Arcispedale S. Maria Nuova, Reggio Emilia, ITALY, [3]Humanitas Gavazzeni, Bergamo, ITALY, [4]AIOU, Verona, ITALY.

Aim: DANTE trial is a randomized study of lung cancer screening with low-dose spiral computed tomography (LDCT). In patients with suspicious lung nodules, the implementation of PET imaging and/or CT-guided core biopsy (CTB) can help improve the diagnostic accuracy and significantly reduce unnecessary and costly surgical procedures. So far however, there is no real evidence that this approach can be cost-effective. The aim of the present study was to analyze the accuracy and economic efficiency of a work-up protocol including such second-line diagnostic investigation (PET-CTB protocol), compared to pure LDCT follow-up (standard protocol) and growth assessment prior to surgical biopsy or return to standard follow-up, in patients with undetermined lung nodules. **Materials and Methods:** Retrospective review of all surgical cases included in the DANTE trial and monitored in our Institution from 2001-2006 for lung cancer screening was performed. Overall, 246 patients and 261 lung nodules were analyzed. The study cohort was divided into patients investigated with PET imaging, CT-guided biopsy, or both (PET-CTB protocol) (N=98), compared to patients monitored with serial LDCT assessment and growth assessment (N=148). Diagnostic accuracy was computed by comparing the performances of the two protocols with tumor histology or long-term monitoring as reference standard. Invoices analyzed in the study comprised outpatient's and inpatient's costs expressed in Euro, as reimbursed by the Italian National Health System. Ineffective costs were defined as the cost of diagnostic procedures leading to potentially avoidable surgical intervention. **Results:** The diagnostic accuracy of the two protocols resulted 94% (sens. 100%, spec. 94%, PPV 36%, NPV 100%) for the standard and 90% (sens. 98%, spec. 80%, PPV 85% and NPV 98%) for the PET-CTB protocol. Average costs for outpatient's diagnostics resulted 694 and 1.462 euro, respectively, for the standard and PET-CTB protocol. Average inpatient's costs for both protocols were 12.121 euro. By applying the costs to diagnostic performance, the two protocols showed comparable effectiveness in terms of total outpatient's costs (94% and 90%, respectively; p=0.361). The inpatient's costs resulted effective for 36% of cases operated according to the standard protocol compared to 85% of cases with the new protocol. Ineffective costs corresponded to 64% and 15% respectively (p<0.0001). **Conclusion:** In front of higher average costs for outpatients diagnostics, the implementation of PET imaging with or without CT-guided core biopsy in the diagnostic protocol of patients with suspicious lung nodules results significantly cost-effective for inpatient's procedures.

E-PW087

User-guided 3D active contour segmentation of complex-shaped tumours : an efficient semi-automatic approach in FDG PET thoracic oncology

F. L. Besson[1,2], T. Henry[1], C. Meyer[1], V. Chevance[1], V. Roblot[1], E. Blanchet[3], V. Arnould[3], G. Grimon[1], M. Chekroun[1], L. Mabille[4], F. Parent[1], A. Seferian[1], S. Bulifon[1], D. Montani[1], M. Humbert[1], P. Chaumet-Riffaud[1], V. Lebon[3], E. Durand[1,2]; [1]AP-HP Universite Paris Sud, Le kremlin bicetre, FRANCE, [2]IR4M-UMR 8081 Université Paris-Sud Université Paris-Saclay CNRS, Orsay, FRANCE, [3]CEA SHFJ, Orsay, FRANCE, [4]CCML, Clamart, FRANCE.

Purpose: PET tumour segmentation is currently an active research topic in the field of radiotherapy planning and multi-parametric data quantification. Although being efficient on homogeneous spheroid-shaped tumours, classical threshold-based approaches are of limited value for heterogeneous or complex-shaped tumours, still making expert-based manual delineation the reference standard for tumour imaging, despite several limitations. In this context, the aim of this study was to assess the performances of an active contour-based approach for the PET segmentation of complex-shaped lung tumours, in comparison to an optimized expert-based manual reference standard. **Subjects and Methods**: Seventy-five thoracic tumours were segmented using the same graphical user interface (GUI) ITK snap software. For each tumour, an optimized expert-based reference standard was generated from the set of six independent expert-based manual segmentation results using the Simultaneous Truth And Performance Level Estimate (STAPLE) algorithm. In addition, four raters semi-automatically segmented the 75 PET tumours twice using the active contour based-procedure of the GUI software, with a delay time of one week between two segmentation sessions. For the 75 tumours, accuracy of the semi-automatic segmentations against the optimized expert-based reference standard was assessed using the DICE similarity coefficient (DSC). Interrater and intrarater reliability analyses were performed using the intra class correlation coefficients (ICC) estimates of the output volumes, along with their 95% confidence intervals (two-way mixed-model, individual-rating, absolute-agreement). For all tumours segmentation procedures, average time per procedure was also estimated. **Results:** Overall accuracy of the semi-automatic procedure was excellent with a DSC of 0.835 (95%CI = 0.775-0.895). Interrater reliabilities provided the following results: ICC = 0.941 (95%CI = 0.913-0.961) for the first session and ICC = 0.935 (95%CI = 0.906-0.956) for the second session. Intrarater reliabilities provided the following results: ICC = 0.993 (95%CI = 0.990-0.996) for the rater 1; ICC = 0.987 (95%CI = 0.976-0.993) for the rater 2; ICC = 0.972 (95%CI = 0.956-0.982) for the rater 3; and ICC = 0.977 (95%CI = 0.964-0.985) for the rater 4. Average time was 631 seconds for manual segmentation procedure and 130 seconds for active contour-based. **Conclusions:** Compared to the state of the art expert-based manual segmentation, the GUI-based active contour procedure provided excellent accuracy and reliability, with a mean procedure duration almost five-times faster than the manual reference procedure. ITK snap software is robust, fast, and easy enough to be routinely applied as a powerful alternative to the manual reference standard in this setting.

E-PW088

In-vivo tumour characterization of breast cancer using [¹⁸F]FDG-PET/CT and supervised machine-learning

L. Papp, T. Nakuz, H. Magometschnigg, M. Grahovac, T. Helbich, G. Karanikas, A. Haug, K. Pinker, T. Beyer, M. Hacker; Medical University of Vienna, Vienna, AUSTRIA.

Introduction: Expression of specific molecular markers such as estrogen (ER), progesterone (PR), HER2 receptors as well as pro-liferation rate (ki67) and tumor grading has direct prognostic and therapeutic implications in breast cancer patient management. To date this assessment must be performed by invasive tissue sampling and analysis. The goal of this study was to establish predictive models for these predictive and prognostic factors using [¹⁸F]FDG-PET/CT and supervised machine-learning (ML). **Subjects and Methods:** Tissue samples of 120 patients with primary breast cancer who underwent ¹⁸FDG breast PET/CT and histopathological tissue analysis including ER, PR, HER2, ki67 and grading (G1-3) before treatment were included in this IRB-approved retrospective analysis. Volume-of-Interest (VOI) of the primary lesion was delineated manually on PET/CT images using the Hybrid-3D software (Hermes Nuclear Diagnostics, Sweden). The VOI activity values were normalized to the mean of the mediastinum to calculate tumour-to-background ratio (TBR). Thirty three features, including first-order (6), histogram (6), shape (2), textural-GLCM (7), textural-GLSZM (8), textural-NGTDM (4) were extracted from the PET TBR and the CT tumour VOIs (33/PET, 33/CT, 66 total). To predict tumour grade, ER, PR, HER2 status and Ki67 values, a multi-Gaussian fuzzy classifier model was utilized for each reference value. To identify relevant features and weights, ML solutions built on evolutionary approaches were utilized in a 10-fold cross-training scheme. The optimized models were validated by comparing their predictive values to the respective reference values in a Monte Carlo cross-validation scheme. Sensitivity, specificity and accuracy were measured for binary classifiers (ER, PR, HER2, Ki67), while accuracy was measured for the multi-class grading classifier. **Results:** The cross-validation revealed the following performance values for the predictive models: Grading: 86% accuracy; ER: 90% sensitivity, 67% specificity and 82% accuracy; PR: 87% sensitivity, 73% specificity and 82% accuracy; HER2: 87% sensitivity, 55% specificity and 64% accuracy; Ki67: 75% sensitivity, 96% specificity and 82% accuracy. **Conclusions:** [¹⁸F]FDG-PET/CT and supervised machine learning allows an accurate non-invasive assessment of predictive and prognostic molecular tumor markers and thus may facilitate a personalized breast cancer treatment.

E-PW089

Evaluation of diagnostic accuracy and impact of FDG PET/CT in pre-operative managment of early breast cancers

P. Chandra, S. Nath, S. Kumar; MIOT international hospital, Chennai, INDIA.

Aim: Exact role of PET/CT in early operable breast cancers remains to be defined. Our aim of this study was to evaluate the diagnostic accuracy of staging PET/CT in early breast cancers and to assess its impact on disease management. **Patients and Methods:** We retrospectively reviewed and analyzed pre-operative PET/CT scans of 70 patients (mean age- 55yrs) done at our institute from the year 2014-2017 with clinically T1-T2 breast cancers (all tumors < 5cm, with or without palpable mobile axillary nodes). 47 patients underwent modified radical mastectomy (MRM) and 15 patients underwent breast conservation surgery (BCS) with sentinel node biopsies. Diagnostic performance of PET/CT for nodal (N) and distant metastases (M) and

its impact on disease management was analyzed using histopathology/clinical follow up as standards of reference. **Results:** PET/CT accurately identified all the primary breast tumors (T1-15 patients, T2- 52 patients, mean size- 2.8cm, mean SUVmax-9.33). 47% patients (n=33) had nodal disease confirmed on final histo-pathological evaluation (HP), noted in 44% of T1 tumors and 46% of T2 tumors. Sensitivity, Specificity, Positive predictive value (PPV), Negative predictive value (NPV), and accuracy of clinical examination for axillary N staging were 65%, 94%, 91%, 76% and 69%. Sensitivity, Specificity, PPV, NPV, and accuracy of PET/CT for axillary N staging were 84%, 89%, 87%, 86 % and 87%. PET/CT identified extra-axillary nodal disease in supraclavicular/internal mammary nodes in 15% (n=7) of patients with T2 tumors; none in T1 tumors, leading to change in radiation treatment planning in these patients. Distant metastasis was accurately identified on PET/CT in overall 11% (n=8) patients (15% of T2 patients and none in T1 patients). Site of distant metastasis included mediastinum/lung (n=5) and skeleton (n=3). 1 patient had FDG uptake in multiple liver lesions- which was identified as adenoma subsequent work up (false positive). Sensitivity, Specificity, PPV, NPV, and accuracy for M staging were 100%, 98%, 88%, 100% and 98% respectively. Surgery was deferred in all the 8 patients with distant metastasis identified on PET/CT. **Conclusion:** PET/CT has high diagnostic accuracy for N and M staging in early breast cancers. Diagnostic yield and impact of PET/CT on disease management is higher in T2 than T1 tumors and alters disease management in overall 15% of patients with T2 tumors by altering the radiation treatment plan and/or identifying distant metastasis.

Myocardial Technetium-99M Methylene Diphosphonate Uptake And Left Ventricular Motion In Transthyretin Related Cardiac Amyloidosis

F. Ticconi[1], A. Nieri[1], I. Calamia[1], V. Ceriani[1], F. Fiz[2], M. Canepa[3], M. Pennone[4], M. Sicignano[4], G. Villa[4], S. Morbelli[4], P. Gancitano[4], G. Sambuceti[1,4], C. Marini[5]; [1]Department of Health Sciences, University of Genoa, Genoa, ITALY, [2]Nuclear Medicine Unit, Department of Radiology, Uni-Klinikum, Tübingen, GERMANY, [3]Cardiovascular Unit, Department of Internal Medicine, University of Genoa,, Genoa, ITALY, [4]Nuclear Medicine Unit, IRCCS San Martino-IST, Genoa, ITALY, [5]CNR Institute of Bioimages and Molecular Physiology, Milan, ITALY.

Purpose: Amyloidosis is an infiltrative disease characterized by extracellular deposition of fibrillary proteins into one or multiple organs. Left ventricular (LV) involvement usually results in restrictive cardiomyopathy up to congestive heart failure. Recognizing underlying process and its severity is an import-

ant task in risk prediction. To this purpose, ^{99m}Tc-methylene diphosphonate (^{99m}Tc-MDP) scan is a low-cost, non-invasive technique with high sensitivity ($\approx$100%) and specificity ($\approx$88%) for detecting cardiac involvement in transthyretin (TTR) related cardiac amyloidosis, even at the early asymptomatic stage. Heart tracer uptake is related to the degree of cardiac amyloid deposition and to LV dysfunction and has a predictive value of major adverse cardiac events. Aim of this study was to evaluate the distribution of ^{99m}Tc-MDP uptake in LV walls of patients with TTR-related cardiac amyloidosis and its correlation with LV wall-motion. **Subjects and Methods:** Ten patients with TTR-related cardiac amyloidosis were submitted to whole body scan 180 minutes after intravenous injection of 555-740 MBq of ^{99m}Tc-MDP. Soon after planar imaging a gated SPECT acquisition was performed dividing R-R interval in eight frames and applying a 20 segments model to LV. Myocardial tracer uptake (MTU) was expressed as % of whole body counts subtracted by the bladder radioactivity content. In ungated SPECT images, uptake distribution in the different LV walls was semi-quantitatively estimated by the product % of maximum myocardial counts in each segment times MTU. Wall motion and wall thickening were estimated by the conventional QGS software. **Results:** Overall, MTU accounted for 2.6±0.7% of whole body counts. Estimated LV ejection fraction was 37±14% and was inversely correlated with MTU (R=-0.50; p<0.05). MTU was heterogeneously distributed, being higher (p<0.05) in the septum (70±6%) with respect to anterior (53±6%), lateral (52±5%) and inferior (55±7%) walls. Finally, a trend toward a negative correlation (R=-0.34, p=0.2) was observed between MTU and regional wall motion in each segment. **Conclusion** Our study supports the idea that septal wall is preferentially involved in TTR related-cardiac amyloidosis resulting in relatively higher ^{99m}Tc-MDP uptake with respect to other LV walls. The agreement between tracer uptake and amount of amyloid infiltration is further supported by the inverse relationship between MTU and functional indexes both on a global and on a regional basis.

E-PW091

Prevalence of heart failure in elderly patients with myocardial uptake on bone scan

L. Mohamed Salem, Sr., J. Sánchez Serna, J. Santos Mateo, M. Perez Martinez, R. Reyes Marles, M. Godoy Bravo, I. Sime Loayza, M. Castellon Sanchez, F. Nicolas Ruiz, L. Frutos Esteban, J. Navarro Ferenandez, M. Tomas Redondo, D. Pascual Figal, M. Claver Valderas; Hospital Clínico Universitario Virgen de la Arrixaca, Murcia, SPAIN.

Introduction: According to scientific evidence from recent literature, myocardial uptake of bone tracers has a high specificity and sensitivity for the diagnosis of cardiac transthyretin amyloidosis, which might be a common and a potential contributor to the development of heart failure with preserved ejection fraction, nevertheless, the real relationship between cardiac amyloidosis seen on bone scan and heart failure, is not fully investigated yet. **Purpose:** To investigate the relationship between myocardial uptake on bone scan and heart failure. **Subjects and Methods:** Together with Cardiology Department

of our hospital, we investigate 105 patients with myocardial uptake on bone scan, 76 men (72.4%), mean age at the moment of the scan is 81.9 (IQR 78.2 - 85.3). We study 91 of 105 patients who performed bone scan with oncological indications, mainly prostate and breast cancers, and 3 patients with rheumatological indications (3.26%). 13 patients from 25 patients, who had myocardial uptake on bone scan, without previous diagnosis of heart failure, underwent the local protocol of heart failure and cardiac amyloidosis at the Heart Failure Unit (Cardiology Department) of our hospital. We also analyzed the causes of death of 40 of 105 patients. **Results:** 25 of 91 patients are diagnosed with heart failure (27,47%), which is considerably higher the theoretical prevalence in the same population (17%). 17 of the 25 patients was hospitalized at least once because of heart failure (68%). The mean NTproBNP is 888 (IQR 233-1971). 13 of the 25 were diagnosed with heart failure after bone scan (52%). The cause of death in 28 patients of 40 (70%) with myocardial uptake on bone scan, were oncological problems, 2 (5%), terminal heart failure, 4 (10%), infection related problems, and 5 (12,5%) is unknown. **Conclusion:** The prevalence of heart failure in elderly patients with myocardial uptake on bone scan is considerably higher than the theoretical prevalence in the same population. Myocardial uptake on bone scan is an earl finding in patients who may develop heart failure later; at the moment of the scan, most patients do not have heart failure. Our results suggest that heart failure and cardiac amyloidosis should be ruled out in patients with myocardial uptake on bone scan.

E-PW092

Bone^{99m}TC-DPD Scintigraphy: More Data To Confirm Its Utility For The Diagnosis Of TTR Heart Amyloidosis In Patients With Restrictive Hypertrophic Myocardiopathy

A. Marí Hualde, E. Ardila Manjarres, R. Pérez Pascual, J. Orcajo Rincón, A. Rotger Regí, L. Reguera Berenguer, J. Alonso Farto; Gregorio Marañón Hospital, Madrid, SPAIN.

Introduction: Cardiac amyloidosis (CA) is a progressive cardiomyopathy with a poor prognosis. The diagnosis is delayed because of the limited specificity of echocardiography and the historical requirement of an histological confirmation. We aim to analyze and evaluate the diagnostic criteria of ^{99m}Tc-2,3-dicarboxypropane-1,1-diphosphonate bone scintigraphy (^{99m}Tc-DPD-BS) in a serie of patients with suspected CA. **Subjects and Methods:** Retrospective study of 54 ^{99m}Tc-DPD-BS between January-2015 and March-2017, that were remitted for suspected CA with restrictive hypertrophic cardiomyopathy by echocardiography. 35/54 were male 64.8%), mean age (79.8years). The studies were evaluated both quantitative and qualitative. Quantitatively, we performed a Left/Right Index (L/R-I) considering pathological &gt 1.5, and qualitatively according to Perugini´s criteria. In addition, the presence of other indirect signs, such as tracer deposit at deltoid and gluteus muscles, at abdominal fat and decrease activity in the femoral diaphysis, were analyzed. The findings were contrasted with those obtained in echocardiographic studies, cardiac magnetic resonance imaging (CMR), genetic tests and clinical follow-up, when pos-

sible. **Results:** Cardiac tracer uptake was evidenced in 15/54 patients (31.25%). We found a clear male predominance (80%), mean age 84.8 years. According to the visual qualitative uptake: 13patients were classified as grade3 (&gt bone) and 2patients as grade2 (= bone). Quantitatively a mean L/R-I:2.2 was found in patients with cardiac pathologic deposition and mean L/R-I:1.05 in patients without cardiac uptake. A 100% correlation was found between the two scales in which all the patients with cardiac deposition had a L/R-I &gt 1.5 and the normal ones &lt 1.5. In addition, it was possible to identify the indirect CA criteria in the 15 patients (100%). 9/15 patients presented a TTR gene sequencing, being just one positive (wild-type), with no scintigraphic differences. Two patients were diagnosed of light chain amyloidosis (LCA), which showed no cardiac deposition, as expected. **Conclusion:** ^{99m}Tc-DPD-BS is a diagnostic tool for TTR-CA (not so for LCA), avoiding the morbidity of cardiac biopsy. Scintigraphic indirect signs should be taken into account. There is a strong correlation between the qualitative scale using a pathological value above 2 and the quantitative one having a cut-off L/R-I &gt 1.5.

E-PW093

Tc99m-DPD scan in the diagnosis of Cardiac Tranthyretin Amyloidosis

L. Mohamed Salem, Sr., J. Sánchez Serna, V. Cabanas Perianes, R. Reyes Marles, M. Godoy Bravo, M. Castellon Sanchez, F. Nicolas Ruiz, L. Frutos Esteban, J. Navarro Ferenandez, I. Sime Loayza, M. Tomas Redondo, M. Perez Martinez, J. Santos Mateo, D. Pascual Figal, M. Claver Valderas; Hospital Clínico Universitario Virgen de la Arrixaca, Murcia, SPAIN.

Introduction: According to late scientific evidence from large multicenter trial, Tc99m-DPD scan has a high specificity and sensitivity for the detection of TTR cardiac amyloidosis, which might be a common cause of heart failure in the elderly. **Purpose:** Our purpose is to study the value of Tc99m-DPD scan in the diagnosis of cardiac TTR amyloidosis. Subjects and **Methods:** Together with the Haematology and Cardiology Departments of our Hospital, we revise retrospectively 50 patients with clinical suspicion of cardiac amyloidosis, who underwent a Tc99m-DPD scan, 2-3 hours after the I.V. injection of 740 MBq. The myocardial tracer uptake was classified into 3 grades, taking as a reference the adjacent rib uptake; grade 1 is less than the rib, grade 2 equal to the rib and grade 3 more than the rib uptake. We select 25 patients with positive scan to analyze their clinical cardiological and haematotological history, blood and urine tests, clinical evolution, final diagnosis, and the results of echocardiography and cardiac MRI. Results:23 patients had intense myocardial tracer uptake grade 3. 2 patients had faint myocardial tracer uptake grade 1, have been diagnosed with primary cardiac amyloidosis. 3 of 23 patients have been diagnosed with primary cardiac amyloidosis (13%). 20 of 23 patients with intense myocardial tracer uptake have been diagnosed with TTR cardiac amyloidosis (87%). **Conclusion:** Tc99m-DPD scan has a 100% specificity in the diagnosis of cardiac TTR amyloidosis. Myocardial uptake is more common in TTR amyloi-

dosis, nevertheless, primary amyloidosis can present also with myocardial uptake, so it must be ruled out in the diagnostic work-up of cardiac amyloidosis.

E-PW094

A comparison between Tc99m-DPD and Tc99m-HDP myocardial uptake in the diagnosis of cardiac amyloidosis

L. Mohamed Salem, Sr., R. Reyes Marles, M. Godoy Bravo, I. Sime Loayza, M. Tomas Redondo, M. Castellon Sanchez, L. Frutos Esteban, J. Navarro Ferenandez, F. Nicolas Ruiz, M. Claver Valderas; Hospital Clínico Universitario Virgen de la Arrixaca, Murcia, SPAIN.

Introduction: According to current scientific evidence from large multicentre trial, myocardial uptake of bone tracers, has a high specificity and sensitivity in the diagnosis of TTR cardiac amyloidosis. Purpose To compare the myocardial uptake of Tc99m-DPD and Tc99m-HDP in the detection of cardiac amyloidosis. **Materials and Methods:** We have investigated the myocardial uptake in 19 patients; 8 with the diagnosis of TTR cardiac amyloidosis, who underwent a Tc99m-DPD and a Tc99m-HPD scan for other indications, 5 with diagnosis of TTR cardiac amyloidosis with Tc99m-DPD scan, who accepted to have a Tc99m-HPD scan, and 6 patients with intense myocardial uptake who had bone scans with both traces. We perform visual inspection and quantitative analysis using heart to mediastinum (H/M) ratio, to assess the myocardial tracer uptake. **Results**: On visual inspection, myocardial tracer uptake was more intense with Tc99m-DPD than Tc99m-HDP in all patients. Individual H/M ratio was higher on Tc99m-DPD than Tc99m-HDP in all patients. Mean H/M ratio was twice higher for Tc99m-DPD (2,17), than Tc99m-HDP (1,11). **Conclusion:** Myocardial Tc99m-DPD uptake is more intense than Tc99m-HDP. Although myocardial tracer uptake would be visible with both tracers in most cases, the grading system may be underestimated, and faint uptake may be missed with Tc99m-HDP. Tc99m-DPD is the radiotracer of choice in the diagnosis of cardiac amyloidosis.

E-PW095

Myocardial uptake of bone scintigraphic agents associated with cardiac amyloidosis in daily practice

S. Fukuzawa, S. Okino, T. Uchiyama, N. Kuroiwa, Y. Iwata, M. Inagaki; Funabashi Municipal Medical Center, Chiba, JAPAN.

The bone scan is primarily used to help diagnose a number of conditions relating to bones, including: cancer of the bone or cancers that have spread (metastasized) to the bone, locating some sources of bone inflammation. Extraosseous uptake, in particular, myocardial uptake, was observed in a number of patient examined with the bone scans. Additionally, in some reports, the uptake of Tc 99m-labeled bone radiotracers in cardiac amyloidosis has been extensively documented. The aim of this study was to assess the patients with high myocardial uptake of bone scintigraphy in daily practice. We retrospectively analyzed the 3435 bone scintigraphies performed in daily practice during a 3-year period. The intensity of the myocardial uptake was graded according to a visual scale ranging from 0 to 3 points, in which the absence of uptake was assigned a score of 0 points; uptake less than that of bone (referred to as the adjacent rib), 1 point; uptake similar to that of bone, 2 points; and uptake greater than that of bone, 3 points. The distribution of the uptake in myocardium was defined as focal uptake, diffuse uptake, uptake in a ventricular wall segment, diffuse ventricular uptake, or diffuse biventricular uptake. The retrospective analysis revealed relatively intense myocardial uptake in 10 of the 3435 patients (0.3%). Eight of the 10 patients had intense Tc-99m uptake (score of 2-3) in the cardiac region, showing deposition in both right and left ventricles in every case, whereas diffuse deposition (score of 1) was observed in 2 patients. In 10 all the cases, the final diagnosis of amyloidosis was based on the results of a biopsy. Cardiac uptake of bone scintigraphic agents were revealed on 0.3% of bone scntigraphies in daily practice. This may be a sign of cardiac amyloidosis involvement which may give extraosseous bone tracer uptake its own importance and a new role.

E-PW096

Is there a relationship between clinical parameters and cardiac uptake in 99mTc-DPD scintigraphy in patients with cardiac amyloidosis?

E. Abou Jokh Casas, V. Pubul Núñez, M. Garrido Pumar, B. Sopeña, A. Varela Roman, M. Pombo Pasin, J. Cortéz, S. Argibay, Á. Ruibal; Complejo Hospitalario Universitario Santiago de Compostela, Santiago de Compostela, SPAIN.

Introduction: Cardiac scintigraphy with 99mTc-3,3-diphosphono-1,2-propanodicarboxylic acid (99mTc-DPD) has been proven useful to differenciate subtypes of cardiac amyloidosis, specially between monoclonal light chain inmunoglobulin (AL) and transthyretin (TTR). Our goal is to correlate cardiovascular risk, electrocardiograhic and ecocardiographic findings, Pro-BNP values and biopsy with different cardiac uptakes in scintigraphy. **Materials and Methods:** We reviewed 40 patients, suspected with cardiac amyloidosis. All patients underwent a 99mTc-DPD scan. Myocardial uptake was graded from 0 to 3, respect to bone uptake. We considered a high cardiovascular risk profile the presence of three or more cardiac risk factors. Electrocardiografic findings included atrial fibrillation (AF) and left bundle branch block (LBBB). Ecocardiographic findings included eyection fraction (EF) and left ventricular hypertrophy (LVH). Pro-BNP was considered positive when a result 10 times higher than normal values was obtained. Cardiac biopsy was performed in 15 patients. **Results:** From our 40 patients, 27.5% presented cardiac uptake between 0-1, 15% had uptake grade 2 and 57.5% uptake grade 3. 63% of the patients with uptake 0-1 had a high cardiovascular risk profile versus 66% in those with uptake grade 2 and 39% in the last group. AF was present in a 27% in the 0-1 group, 66% in the group with uptake 2 and 52% in the uptake 3 group. 18% had LBBB with uptake 0-1, 16% patients with uptake 2 and 34% patients with uptake 3. EF was decreased in 36% of patients with grade 0-1 versus 33% in grade 2 group and 56% in

grade 3 group. LVH was present in 90% of the patients included in the 0-1 group, versus 83% in the group with uptake 2 and 56% in the grade 3 uptake group. Pro-BNP levels were found elevated in 50% of the 0-1 group versus 56% in the grade3 group. 12 of 15 patiens with cardiac biopsy were positive for ATTR, and all of them presented grade 3 uptake. **Conclusions:** The presence of a higher 99mTc-DPD uptake was mainly related with the prevalence of atrial fibrilation and decreased EF. This was also associated with a positive biopsy for ATTR. The relationship with the cardiovascular risk profile and Pro-BNP is doubtful.

E-PW097
Clinical Utility of ^{99m}Tc-PYP and ^{201}Tl-Cl SPECT Imaging in Patients with Suspected Cardiac Amyloidosis

S. Ito, N. Kodani, K. Tanabe; Shimane University, Izumo, Shimane, JAPAN.

Introduction: The degree of myocardial 99mTc-PYP accumulations in cardiac amyloidosis (CA) is conventionally evaluated as the PYP score. This method involves qualitative visual evaluation on two-dimensional images. Recently evaluation with heart to contralateral ratio is used as quantitative analysis, but is often affected artifact. **Purpose:** We validated the ability of three-dimensional quantitative analysis. Methods: One-handed-fifty-four consecutive patients suspected CA underwent 99mTc-PYP and 201Tl-Cl SPECT. Patients received 740MBq of 99mTc-PYP and 74MBq of 201Tl-Cl. We evaluated the PYP score in five phase of the planar image. In addition, we made left ventricular myocardial mask image from 201Tl-Cl images. The mask was applied to the 99mTc-PYP images using the coordinates of the myocardium and ventricular cavity. We quantitatively analyzed on a voxel-by-voxel basis from three-dimensional coordinate axis. Thus we quantitatively calculated the PYP accumulation rates. **Results:** Mean age of population was 72±12 years, and 58% were males. Twenty-eight patients had biopsy proven systemic amyloidosis (11 ATTR, 7 AL, 10 others). When the threshold of the PYP score was defined as 3+ and that of the PYP accumulation rate as 32.6%, the sensitivity of the PYP score and PYP accumulation rate were 57.0% and 75.0% and the specificity were 80.2% and 84.1% respectively. ATTR type presented a higher accumulation rate (96.1%±11.5%) than AL type (53.6%±28.7%, p=0.012, Fig.1). **Conclusions:** Our quantitative evaluation with the PYP accumulation rates may be useful in the diagnosis of CA and type of CA compared with conventional qualitative evaluation.

E-PW098
Florbetaben Whole-Body PET/MRI for Evaluation of Systemic Amyloid Deposition

S. Park, L. Baratto, P. Gulaka, R. Herfkens, R. Witteles, A. Iagaru; Stanford University School of Medicine, Stanford, CA, UNITED STATES OF AMERICA.

Background: Florbetaben, a ^{18}F-labeled stilbene derivative (formerly known as BAY-949172, trade name Neuraceq), is a diagnostic radiopharmaceutical developed to visualize β-amyloid plaques in the brain. Here we report a pilot study evaluating patients with suspected cardiac amyloidosis for systemic extent of disease. **Methods:** We enrolled 4 men and 1 woman referred from the cardiac amyloid clinic, 61-80 year-old (mean±SD: 69.8±7.1) in a prospective study using the GE SIGNA PET/MRI. First, dynamic imaging of the heart was acquired immediately after injection of 6.0-8.1 mCi (mean±SD: 7.1±0.8) of Florbetaben. This was followed by a whole-body PET/MRI scan 60-113 minutes (mean±SD: 84.2±23.2) after injection. Cardiac MRI sequences included ECG-triggered cine SSFP, T2-weighted, and late gadolinium-enhanced imaging. Whole-body MRI sequences included MRAC and axial T1-weighted imaging. **Results:** High early uptake and delayed high uptake in the left ventricle correlated with amyloid deposition in 3 patients, while low uptake on early and delayed cardiac imaging was noted in 2 patients. Measurements of cardiac function (left ventricle ejection fraction, volumes, peak filling, peak flow, etc) were successfully measured in all participants. Areas of abnormal Florbetaben were noted on delayed whole-body imaging in the brain (2 patients), ocular muscles (2 patients), salivary glands (4 patients), thyroid (1 patient), pleura (1 patient), stomach (diffuse in 3 patients and focal in 2 patients), spleen (1 patient), kidneys (3 patients) skeletal muscles (2 patients) and bone marrow (4 patients). **Conclusions:** Florbetaben is a promising PET radiopharmaceutical for localization of systemic amyloid deposition that used in conjunction with PET/MRI may provide important structural and functional information regarding the organs involved by disease.

E-PW099
^{18}F-FDG-PET/CT as a diagnostic tool in native valve endocarditis

I. Kouijzer[1,2], M. Berrevoets[1], E. Aarntzen[1], M. Janssen[1], J. de Vries[1], A. van Dijk[1], W. Oyen[1,3], L. de Geus-Oei[4,2], C. Bleeker-Rovers[1]; [1]Radboudumc, Nijmegen, NETHERLANDS, [2]University of Twente, Enschede, NETHERLANDS, [3]The Institute of Cancer Research and Royal Marsden NHS Foundation Trust, London, UNITED KINGDOM, [4]LUMC, Leiden, NETHERLANDS.

Introduction: Diagnosing infective native valve endocarditis (NVE) is challenging. The modified Duke criteria are currently used for diagnosing infective endocarditis, but have limited sensitivity. We investigated the value of ^{18}F-fluorodeoxyglucose positron emission tomography with combined computed tomography (^{18}F-FDG-PET/CT) to diagnose NVE. **Subjects and Methods:** All patients with bacteremia and suspicion of NVE between January 2013 and June 2016 were identified from the hospitals' register and included if echocardiography and ^{18}F-FDG-PET/CT were performed within 14 days. ^{18}F-FDG-PET/CT scans were scored independently by two nuclear medicine physicians. Diagnostic accuracy of ^{18}F-FDG-PET/CT was determined using the modified Duke criteria and a multidisciplinary consensus as a reference standard. **Results:** Eighty-eight patients were included. As compared to the modified Duke criteria; sensitivity, specificity, PPV, and NPV for ^{18}F-FDG-PET/CT in diagnosing

definite NVE were 30.0%, 89.7%, 27.3%, and 90.9%. Compared to definite diagnosis by multidisciplinary consensus; sensitivity, specificity, PPV, and NPV for ^{18}F-FDG-PET/CT were 35.0%, 94.1%, 63.6%, and 83.1%. Mortality rates in patients with possible and rejected NVE according to the modified Duke criteria was higher when the heart valve region showed increased ^{18}F-FDG uptake. Metastatic infectious foci were detected by ^{18}F-FDG-PET/CT in 54.5% of patients. **Conclusions:** ^{18}F-FDG-PET/CT lacks accuracy for diagnosing NVE. In patients with possible NVE according to the modified Duke criteria, ^{18}F-FDG-PET/CT could be used in case of sustained suspicion of NVE because of its good specificity. In patients suspected of NVE, ^{18}F-FDG-PET/CT is important for detecting metastatic infection.

Effect of blood flow on ^{18}F-Florbetaben PET quantitation: a simulation study

S. Bullich[1], N. Koglin[1], G. Becker[2], S. De Santi[3], A. Jovalekic[1], H. Barthel[3], O. Sabri[3]; [1]Piramal Imaging GmbH, Berlin, GERMANY, [2]Department of Nuclear Medicine, University Hospital Leipzig, Leipzig, Leipzig, GERMANY, [3]Department of Nuclear Medicine, University Hospital Leipzig, Leipzig, GERMANY.

Introduction: Cerebral blood flow (CBF) changes over time have been reported in Alzheimer's disease patients (van Berckel B. et al. J Nucl Med. 2013; Ottoy J. et al J Nucl Med. 2017). Standardized uptake value ratios (SUVR) are commonly used to analyze ^{18}F-Florbetaben PET scans. SUVRs, however, may be biased as surrogate marker of beta-amyloid (Aβ) load by BF effects. This is relevant in longitudinal studies and anti-Aβ therapeutic trials where a drug is administered and its effect on CBF is unknown. The objective of this study was to assess the impact of CBF changes on SUVR and non-invasive kinetic models in ^{18}F-Florbetaben PET scans. **Subjects and Methods:** Average arterial input function and rate constants (K_1, k_2, k_3 and k_4) from 10 AD subjects scanned with ^{18}F-Florbetaben PET were used to generate simulated time-activity curves by means of a two-tissue compartment model from 0 to 140 min. Two simulations were carried out: 1) regional CBF change affecting only cortical regions (i.e. average K_1 from the AD subjects (K_1=0.2) varied between 0.15 and 0.25 (±25%) while keeping K_1/k_2 constant); 2) global CBF change affecting cortical and reference regions (i.e. average K_1 varied between 0.15 to 0.25 while keeping $R_1=K_1/K_1'$ constant). The binding potential (BP_{ND}) in all the simulations was 0.59. Aβ load was quantified using the simplified reference tissue model (SRTM) (Gunn RN. et al. Neuroimage. 1997) and two multilinear reference tissue models (MRTM and MRTM2)(t^*=70 min) (Ichise M. et al. J Cereb Blood Flow Metab 2003). SUVRs were determined at 70-90, 90-110 and 120-140 min. The bias associated with CBF changes was quantified as the percent change in the Aβ load estimates from the simulated BP_{ND} ($BP_{ND,sim}$=0.59) (bias(%)=100·ΔBP_{ND}/ $BP_{ND,sim}$). **Results:** For the regional CBF change, MRTM provided accurate Aβ load estimates independent of the BF (ΔBP_{ND}=0.02 (bias=3.5%)(MRTM); ΔBP_{ND}=0.05 (8.2%)(MRTM2)). SUVR provided estimates of the Aβ load with a limited CBF effect, which got reduced at late time points (ΔSUVR-1= 0.08 (13.5%)(70-90 min); 0.06 (10.9%)(90-110 min); 0.02 (3.6%)(120-140 min)). SRTM provided CBFdependent estimates of the Aβ load (ΔBP_{ND}=0.24 (40.0%)). Global CBF change did not substantially bias the Aβ load estimates for any of the measurements (<7%). **Conclusion:** In ^{18}F-Florbetaben PET imaging, Aβ load estimates as obtained by SUVRs from late time points or by MRTM are less influenced by CBF changes. Thus, for longitudinal studies in which a maximum quantification accuracy is desired, these methods should be applied.

E-PW101

Can relative flow derived from dynamic ^{11}C-PIB scans replace FDG scans in Alzheimer disease PET studies?

T. van der Goot, F. E. Reesink, D. E. Peretti, D. Vállez García, A. T. M. Willemsen, P. P. De Deyn, R. Boellaard; UMCG, Groningen, NETHERLANDS.

Aim: Different PET biomarkers are used for the differential diagnosis of neurodegenerative diseases such as Alzheimer's disease (AD). β-amyloid plaque deposition can be assessed by ^{11}C-Pittsburgh Compound B (PIB) while ^{18}F-fluorodeoxyglucose (FDG) is used to assess cerebral glucose metabolism, which can be an indicator for synaptic dysfunction. Although FDG is a biomarker for glucose consumption, its distribution is strongly affected by cerebral perfusion. The aim of the study is to explore whether relative blood flow (rCBF) data, extracted from dynamic ^{11}C-PIB studies, can be used as a surrogate for relative FDG distributions. **Methods:** Thirty subjects (10 AD, 10 mild cognitive impairment (MCI) patients, and 10 healthy controls (HC)) underwent static ^{18}F-FDG (45-60 min p.i.) and 70 min dynamic ^{11}C-PIB PET scans. T1-MRI scans were used for anatomical labelling of brain regions. Parametric ^{11}C-PIB rCBF images (R_1: tracer delivery relative to the cerebellum) were obtained using the simplified reference tissue model 2 (SRTM2, PMOD v3.8). ^{18}F-FDG images were normalized to the cerebellar grey matter values (SUVr). The Hammers atlas was used to analyze regional correlations between R_1 and SUVr. We used SPM12 to compare SUVr and R_1 statistical parametric maps between AD and HC. **Results:** The regional analysis showed strong correlations between R_1 and SUVr for AD, MCI and HC (group average R^2 of 0.89 (AD), 0.90 (MCI) and 0.84 (HC)). Both R1 and SUVr showed similar statistical parametric maps for AD and HC which are in agreement with previous reports in literature. However, SPM based on R1 showed a smaller number of significant clusters involved than with the SPM based on FDG SUVr. In addition, the clusters found in R1 were smaller in size and T-value. For example, in the left inferiolateral parietal lobe FDG SUVr showed 2297 voxels(mean(T)=5.4) versus 999 voxels for R1(mean(T)=4.7). **Conclusion:** Relative cerebral perfusion images (R_1) obtained from ^{11}C-PIB dynamic PET acquisitions are strongly correlated with normalized ^{18}F-FDG im-

ages in all 3 groups and largely show the same SPM pattern in a group comparison. However, the observed group differences for R_1 were smaller and less significant which may be related to the lower signal-to-noise ratio of the R_1 images. These preliminary results suggest that dynamic ^{11}C-PIB PET can not only be used to asses β-amyloid plaque deposition, but that relative rCBF derived from these scans can in some cases be used to replace FDG thereby obviating the need to perform a second tracer (FDG) study.

Different Patterns of Dopamine and Serotonin Dysfunction in Manic, Depressive and Euthymic Phases of Bipolar Disorder

S. Nikolaus, H. Müller, H. Hautzel; University Hospital Düsseldorf, Düsseldorf, GERMANY.

Purpose/Introduction: A variety of alterations in brain neurotransmitter systems has been proposed as the underlying neurochemical cause of bipolar disorder (BD) including dopamine (DA), serotonin (5-HT) and acetylcholine (ACh). In the present study, we evaluated the contribution of the individual synaptic constituents of all assessed neurotransmitter systems by subjecting all available in vivo imaging studies in manic (BD-man), depressive (BDdep) and euthymic BD patients (BDeu) to a retrospective analysis. **Subjects & Methods:** In patients with BDman (n=39), BDdep (n=248) and BDeu (n= 265) DA synthesis, DA release or binding to DAT, VMAT2, D1 receptor [R], D2R, SERT, 5-HT1AR, 5-HT2AR, M2R and beta2-nAChR was assessed in various cortical and subcortical regions with either PET or SPECT and compared to healthy individuals. Studies were pooled and median values and interquartile ranges of percentual differences relative to controls were determined for the individual brain regions. Differences to controls were assessed with the Wilcoxon-signed-rank-test. **Results:** Findings showed elevated midbrain SERT, decreased parietal, temporal, occipital, insular and fusiform 5-HT2AR and decreased frontal D1R in BDman. BDdep was characterized by decreased hippocampal, but elevated insular SERT, elevated prefrontal, frontal, hippocampal, amygdalar and periaqueductal 5-HT1AR, decreased frontal D1R and decreased prefrontal, frontal, occipital and cingulate M2R. BDeu still showed decreased striatal, thalamic and midbrain SERT, decreased striatal DA synthesis, elevated striatal DAT, elevated thalamic and midbrain VMAT2, decreased frontal D1R and decreased striatal D2R. **Discussion/Conclusion**: From these findings, a complex pattern of dysregulations within and between neurotransmitter systems may be inferred, which is causally linked to the acute and euthymic states of BD. While increased mesencephalic and parietotemporoccipital 5-HT and increased frontal DA underlie BDman, BDdep may be characterized by decreased frontal and limbic 5-HT, increased frontal and limbic ACh and increased frontal DA. Also in euthymia, no normalization of receptor and transporter densities was observed. They act together, however, to achieve a normalization of mesencephalic, cortical and limbic 5-HT.

First quantification results for the new TSPO radioligand [^{18}F]GE-180 in patients with multiple sclerosis

L. Vomacka[1], N. L. Albert[1], S. Lindner[1], M. Unterrainer[1], C. Mahler[2], M. Brendel[1], L. Ermoschkin[1], A. Gosewisch[1], A. Brunegraf[1], C. Buckley[3], W. Trigg[3], T. Kümpfel[2], R. Rupprecht[4], M. Kerschensteiner[2,5], P. Bartenstein[1,5], G. Böning[1]; [1]Department of Nuclear Medicine, LMU Munich, Munich, GERMANY, [2]Institute of Clinical Neuroimmunology, LMU Munich, Munich, GERMANY, [3]GE Healthcare, Grove Centre, Amersham, UNITED KINGDOM, [4]Department of Psychiatry and Psychotherapy, University of Regensburg, Regensburg, GERMANY, [5]Munich Cluster for Systems Neurology (SyNergy), Munich, GERMANY.

Purpose: The objective of this study was to verify simplified quantification methods for the new TSPO radioligand [^{18}F]GE-180. Focal lesions and different brain regions of patients with multiple sclerosis (MS) were analysed, focusing on a high inter- and intra-patient comparability and an efficient integration into clinical routine. **Methods:** A total of 15 dynamic 90 minutes [^{18}F]GE-180 PET scans of MS patients was performed, where 7 scans were combined with manual blood-sampling for modelling based on free parent tracer in plasma. Quantification started with two-tissue-compartment (2TC) and graphical models. This was followed by an investigation regarding the least disease-affected brain tissue, which included a voxel-based comparison with data from 7 healthy controls (HC) with statistical-parametric-mapping and a comparison of brain VOI characteristics. For the definition of a final pseudo-reference region (PRR) voxels suspicious of being affected by disease were excluded by the application of an upper threshold based on mean and standard deviation from HC data in static 60 to 90 minutes images. Binding potentials (BP) estimated from static images normalized to PRR (standardized uptake value ratio SUVR, $BP_{Ref'60-90}$=SUVR-1) were correlated to BP_{ND} relative to non-displaceable uptake from 2TC model and to BP_{Ref}=V_T/V_{PRR}-1 relative to reference tissue from 2TC model, Logan-Plot and Logan-reference tissue model. SUVR was quantified for different brain VOIs and 59 focal lesions visible in PET. Lesion volumes were delineated in SUVR images with an iterative thresholding approach and a simplified threshold method. **Results:** Average SUVRmean of lesions was 1.8 (range 1.2; 3.0) and SUVRmax was 2.4 (range 1.3; 4.8). Mean SUVR in MS patients was highest in thalamus and brainstem (1.3), and lowest (1.1) in white matter (WM) and grey matter (GM). WM, thalamus and brainstem exhibited the highest mean fractions of voxels suspicious of being affected by disease (>30%) and frontal cortex (FC) the lowest (16%). Normalization to FC yielded the highest reduction in variability of healthy WM and GM. Therefore FC corrected for affected voxels was chosen as PRR. The average time-activity curves and BP_{ND} of the PRR corresponded to FC values in HC data (BP_{ND} 2.2, U-test p=0.83). BP_{ND} correlated strongly with $BP_{Ref'60-90}$ (Spearman rho=0.85), and BP_{Ref} from 2TC model and Logan methods showed very strong correlation with $BP_{Ref'60-90}$ (rho>0.9). **Conclusion:** This preliminary comparison with modelling parameters from dynamic PET scans suggest that $BP_{Ref'60-90}$ relative to not-affected frontal cor-

tex derived from static images might be suitable for [18F]GE-180 quantification in MS patients.

E-PW104

PET-Analysis: a user-friendly toolbox for epileptic seizure onset zone localization. Evaluation of the performance using simulated data

A. Niñerola-Baizán[1,2], B. Marti-Fuster[1,2], A. Martín-Pero[2], R. Tudela[1], M. Mayoral[3], X. Setoain[3,1], D. Ros[2,1], J. Pavía[3,1]; [1]Grupo de Imagen Biomédica, Centro de Investigación Biomédica en Red en Bioingeniería, Biomateriales y Nanomedicina (CIBER-BBN), Barcelona, SPAIN, [2]Unitat de Biofísica i Bioenginyeria, Facultat de Medicina, Universitat de Barcelona, Barcelona, SPAIN, [3]Servicio de Medicina Nuclear, Hospital Clínic, Barcelona, SPAIN.

Introduction: Visual inspection is commonly used in clinical practice during the assessment of [18F]FDG-PET studies for presurgical evaluation of refractory epilepsy. However, a voxel-by-voxel statistical analysis comparing the [18F]FDG-PET study of the patient to a control database can improve the localization of the hypometabolic zone related to the epileptogenic region (ER). **Aim:** To assess the clinical utility of PET-Analysis, a toolbox based on statistical parametric maps to aid clinicians in the localization of the ER in refractory epileptic patients. **Methods**: Realistic simulations based on 5 clinical studies with Magnetic Resonance Image (MRI), Computed Tomography (CT) and PET were simulated using SimSET v2.9 Monte Carlo code. The attenuation and the activity maps were obtained from structural CT and MRI and functional PET images. ERs were defined in twelve commonly observed regions in epilepsy. Activity maps (n=180) were generated together with hypometabolism levels of 15%, 30% and 45% in the ER. Simulated studies were reconstructed like the clinical data, spatially normalized into our own [18F]FDG template, smoothed with a Gaussian kernel of FWHM=8x8x8mm^3 and intensity normalized. To detect the simulated regional hypometabolism, a *t*-test between each simulated study and the control database was performed. Each resulting statistical parametric map was thresholded by a *t*-value (t_{th}) and cluster size (k_{min}) in two steps. In step one, the values of t_{th} and k_{min} were set to 3.39 (p<0.001), and 100 in line with earlier studies. In the second step, in the absence of a cluster, t_{th} was diminished and different cluster sizes were used to detect only one surviving cluster. ER was considered as detected if it intersected one of the surviving clusters in step one or the only one in step two. **Results**: As regards detectability, when the initial *t*-value and k were used (p<0.001,k=100), the number of ER detected were 4/60 for 15% hypometabolism, 41/60 for 30% hypometabolism and 59/60 for 45% hypometabolism, with more than one cluster in some images. On the other hand, when a dynamic statistical threshold was used and only one cluster was spotted, the number of ER correctly detected were 31/60 for 15% hypometabolism, 55/60 for 30% hypometabolism and 60/60 for 45% hypometabolism. **Conclusion**: PET-Analysis is a useful tool to localize the ER in refractory epilepsy. A dynamic statistical threshold is recommended to improve localization, starting with a high *t-value* (i.e. low *p*-value) and a low k_{min} and ending with a low *t-value* and a high k_{min}.

E-PW105

123I-Ioflupane scintigraphy in asymptomatic LRRK2-G2019S mutation carriers

I. Martínez-Rodríguez[1], M. Jiménez-Alonso[1], J. López-Defilló[1], J. Infante[2], M. Sierra[2], J. Jiménez-Bonilla[1], N. Martínez-Amador[1], M. De Arcocha-Torres[1], F. Gómez-de la Fuente[1], D. Meza-Escobar[1], I. Banzo[1]; [1]Nuclear Medicine Service. Marqués de Valdecilla University Hospital. Molecular Imaging Group (IDIVAL). University of Cantabria, Santander, SPAIN, [2]Neurology Service. Marqués de Valdecilla University Hospital. IDIVAL. Centro de Investigación Biomédica en Red de Enfermedades Degenerativas (CIBERNED). University of Cantabria, Santander, SPAIN.

Purpose: LRRK2-G2019S mutation is one of the known causes for Parkinson disease (PD). It has an incomplete penetrance of 30-90% at 80 years, making it difficult to know which patients are going to develop the disease. Our aim was to evaluate the contribution of 123I-Ioflupane scintigraphy as a predictor of PD development in asymptomatic mutation carrier patients. **Materials and Methods:** This prospective study included 25 subjects, asymptomatic carriers of the LRRK2-G2019S mutation (7 men; 58.2±10.3 years). An initial and 4- year follow-up 123I-Ioflupane scintigraphy were obtained in all subjects. Images were acquired 3 hours after IV injection of 150 MBq of 123I-Ioflupane. A visual and manual semiquantitative analysis was performed evaluating both the striatum globally and each nucleus separately. Occipital region was selected as background. Striatum/occipital, putamen/occipital and caudate/occipital ratios were calculated. Initial and follow-up results were compared and correlated with the clinical outcome. Three subjects developed PD at 4 years. **Results:** <u>Visual analysis</u>: Initial 123I-Ioflupane was normal in 15 out of 25 subjects (60%) and abnormal in 10 (40%), showing 6 of them a bilateral involvement. At follow-up, 123I-Ioflupane remained normal in 7 out of 25 subjects (28%) and was abnormal in 18 (72%) subjects (the 10 subjects with abnormal initial scan and 8 subjects with normal initial scan). The more intense involvement was observed at the putamen nucleus. The 3 asymptomatic subjects who developed PD had an abnormal initial and follow-up 123I-Ioflupane scan. None of the subjects with normal initial 123I-Ioflupane developed PD. <u>Semiquantitative analysis</u>: Initial striatum/occipital ratios were significantly lower (p<0.01) for the 3 PD-converters compared to the 22 non-converters (right 0.9±0.1 and left 0.9±0.1 vs. right 1.6±0.3 and left 1.6±0.4, respectively). The same behavior was observed for the follow-up examinations (right 0.6±0.1 and left 0.5±0.1 vs. right 1.3±0.3 and left 1.3±0.3, p<0.01). Visually normal subjects whom became abnormal at follow-up had initial striatum/occipital ratios lower than subjects with both normal initial and follow-up scans, but the differences were not significant (p = 0.1533 and 0.1323 for the right and left striatum, respectively). **Conclusions:** 123I-Ioflupane scintigraphy demonstrated a decline of striatal dopamine transporter binding in a high percentage of asymptomatic carriers of the LRRK2-G2019S mutation and could be a useful tool as predictor of PD development. These preliminary results should be confirmed with a longer-term follow-up.

Impact of Resolution Recovery Reconstruction on Quantitative Analysis of PETCT beta-Amyloid Plaque Brain Imaging

R. T. Meades[1], L. M. Perry[1], K. S. Nijran[1], Z. Win[2];
[1]Radiological Sciences Unit, Imperial College Healthcare NHS Trust, London, UNITED KINGDOM, [2]Nuclear Medicine Department, Imperial College Healthcare NHS Trust, London, UNITED KINGDOM.

Introduction: β-amyloid plaque density Positron Emission Tomography (PET) brain imaging is used for patients being evaluated for Alzheimer's Disease and computer aided quantitative analysis could be used to aid their reporting. Resolution recovery reconstruction algorithms may also be used to increase resolution, improving visual differentiation between grey and white matter in the brain which may increase diagnostic confidence. This work aimed to assess the impact of using a resolution recovery reconstruction algorithm on results from dedicated quantitative analysis software. **Method**: 12 F-18 Florbetapir (Amyvid, Ely Lilly) scans (6 negative and 6 positive) were reconstructed using Siemens TrueX resolution recovery algorithm (4 iterations, 16 subsets, 2mm Gaussian filter, 256x256 matrix, 2x zoom) as well as the recommended iterative reconstruction (4 iterations, 14 subsets, 3mm Gaussian filter, 168x168 matrix, 2x zoom). BRASS for Amyvid (HERMES Medical Solutions) was used to analyse the datasets fitting and comparing images to a reference normal template, producing SUV ratios (SUVr) for 6 regions relative to the cerebellum and an average ratio of all regions (SUVr$_{ave}$) for each scan. **Results**: When comparing the resolution recovery reconstruction with the recommended iterative reconstruction in the negative scans, statistically significant increases in SUVr were noted for 3 regions; Frontal Medial Orbital Cortex (+3.9%, p=0.02), Lateral Temporal (+4.2%, p =0.01) and Parietal (+4.4%, p=0.01). For the positive scans statistically significant increases were noted in 2 regions; Lateral Temporal (+3.3%, p=0.03) and Parietal (+4.5%, p=0.02). For all 6 negative scans, SUVr$_{ave}$ demonstrated a statistically significant increase (+2.9%, p=0.03). In 4 of the 6 positive scans SUVr$_{ave}$ increased with 2 unchanged. This change was not statistically significant (2.4%, p=0.08). **Conclusion**: The use of a resolution recovery reconstruction algorithm lead to an overall increase in region specific SUVr and SUVr$_{ave}$ compared with recommended iterative reconstruction parameters. This increase is greater in average magnitude, more statistically significant and is present in more regions for negative than for positive scans. Both negative and positive scans exhibit increases in the Lateral Temporal and Parietal regions while an increase is also observed in the Frontal Medial Orbital Cortex for negative scans. The greater effect on negative compared to positive scans highlights that care should be taken when choosing to use resolution recovery reconstruction algorithms in this setting. However, further work is required to determine the likelihood and severity of impact on clinical diagnosis.

Asymmetric Parkinson's disease and effects of unilateral subthalamic nucleus deep brain stimulation on neural networks: a pilot PET study

P. David[1], X. Palard-Novello[2], S. Drapier[3], M. Verin[3], F. Le Jeune;
[1]Hôpital Européen Georges Pompidou, Paris, FRANCE, [2]Centre Eugene Marquis, Rennes, FRANCE, [3]Centre Hospitalier Universitaire, Rennes, FRANCE.

Purpose: Parkinson's disease is often defined as a bilateral form of motor symptoms but some patients have a purely unilateral or very asymmetric form for many years. It is described that motor and non-motor symptoms are different between right or left form so we hypothesized that cerebral metabolism would be different depending on the side of disease. Subthalamic nucleus (STN) deep brain stimulation (DBS) is well established for many years for patients with intractable and advanced Parkinson's disease. Bilateral STN DBS has shown a significant motor improvement, but would induce metabolic changes on associative and limbic circuits and is associated with risks and costs. Unilateral surgery would be an interesting alternative for patients with extremely asymmetric symptoms. We also hypothesized that unilateral STN DBS would act differently on brain networks, depending of side of surgery. Subjects & Methods: We studied glucose cerebral metabolism in eleven patients with unilateral or asymmetric symptoms of Parkinson's disease, who underwent 18F-FDG-PET 3 months before and 3 months after unilateral STN DBS. Six patients underwent left STN DBS while five patients underwent a right surgery. Motor, psychiatric and neuropsychological assessments were also performed at each step, and Statistical Parametric Mapping software (SPM) was used for analysis data. We first analyzed pre-operative metabolism at rest of these patients compared to eleven age-matched healthy subjects and secondly we studied metabolic effects following unilateral STN DBS. **Results:** Parkinson's disease modify cerebral metabolism at resting state differently between left and right-affected hemisphere with more metabolic changes in patients candidate for right-STN DBS. The comparison between pre and post-operative metabolism showed bilateral but asymmetric effects, predominantly on the side of DBS. For patients with left symptoms, right-STN DBS induce different metabolic changes compared to left surgery, predominantly in right hemisphere and especially on limbic areas. All patients had significant motor improvement at 3 months after surgery. Discussion: The results of this pilot PET study showed that Parkinson's disease in patients with highly asymmetric symptoms modify differently the cerebral metabolism, depending on the side of hemisphere affected, possibly by acting on the Default Mode Network. Right or left surgery seems to induce different metabolic changes particularly on associative and limbic networks, probably explained by differences in functional connectivity between cortical areas and right versus left STN. These preliminary results could offer hypothesis for new therapeutic approaches such as different targets of repetitive transcranial magnetic stimulation (rTMS) depending of side of disease.

E-PW108

Cortical metabolic patterns related to CSF total tau, Aβ42 and phosphorylated tau protein in Alzheimer disease

A. Chiaravalloti[1,2], M. Ricci[3], A. Martorana[4], F. Calabria[5], P. Sannino[2], O. Schillaci[1,2]; [1]Department of Biomedicine and Prevention, University Tor Vergata, Rome, ITALY, [2]IRCCS Neuromed, Pozzilli, ITALY, [3]Nuclear Medicine Unit, University La Sapienza, Rome, ITALY, [4]Department of Neusociences, University Tor Vergata, Rome, ITALY, [5]Neuroimaging PET/MRI Research Unit, Institute of Molecular Bioimaging and Physiology, National Research Council, Catanzaro, ITALY.

Aims: physiopathological mechanisms of Alzheimer's disease (AD) are still matter of debate. Especially the role of amyloid β and tau pathology in the development of the disease are still matter of debate. Changes in tau and amyloid β peptide concentration in cerebrospinal fluid (CSF) and hypometabolic patterns at fluorine-18 fluorodeoxyglucose (18F-FDG) PET scanning are considered as biomarkers of AD.The present study was aimed to evaluate the relationships between the concentrations of CSF total Tau (t-Tau), phosphorilated Tau (p-Tau) and Aβ(1-42) amyloid peptide with 18F-FDG brain distribution in a group of patients with AD. **Materials and Methods**: We examined 131 newly diagnosed AD patients according to the NINCDS-ADRDA criteria. The mean (± SD) age of the patients was 70 (± 7) years; 57 were male and 74 were female. All patients underwent a complete clinical investigation, including medical history, neurological examination, mini-mental state examination (MMSE), a complete blood screening (including routine exams, thyroid hormones and a complete neuropsychological evaluation. Structural MRI was performed not earlier than 1 month before the 18 F-FDG PET/CT. The following patients were excluded: those with isolated deficits and/or unmodified MMSE (=25/30) on revisit (period of follow-up: 6, 12 and 18 months); patients who had had a clinically manifest acute stroke in the last 6 months with a Hachinsky score greater than 4; and patients with radiological evidence of subcortical lesions. All AD patients were taken off cholinesterase inhibitor treatment throughout the study. We performed lumbar puncture and CSF sampling for diagnostic purposes 2 weeks (± 2 days) before the PET/CT scan. The relationship between brain 18F-FDG uptake and CSF biomarkers was analysed using statistical parametric mapping (SPM8; Wellcome Department of Cognitive Neurology, London, UK) implemented in Matlab R2012b using the MMSE score, sex and age, and other CSF biomarkers as covariates. **Results:** t-Tau, p-Tau and Aβ(1-42) in CSF resulted 774±345 pg/ml, 98±64 pg/ml and 339±118 pg/ml respectively. SPM analysis showed a significant negative correlation between CSF t-Tau and 18F FDG uptake in right temporal lobe (Brodmann areas, BA, 20 and 38; P fdr and few corr < 0.001, k_e 2422), right parietal lobe (BA 40, P fdr and few corr < 0.001, k_e 548) and right frontal lobe (BA 8 and 9, P fdr and few corr < 0.001, k_e 4930). We did not find any significant relationships with other CSF biomarkers. **Conclusions:** t-Tau deposition in brain is related to temporal-parietal and frontal hypometabolism in AD.

E-PW109

18F-FDG PET brain in presurgical management of patients with periventricular nodular heterotopias related epilepsy: diagnostic features and long term outcome

C. E. Popescu[1], C. Rossetti[1], R. Mai[1], R. Sara[1], M. Milella[1], D. Redaelli[1], A. Liuni[1], F. Caobelli[2]; [1]Niguarda Hospital, Milan, ITALY, [2]University Hospital Basel, Basel, SWITZERLAND.

Introduction: Periventricular Nodular Heterotopias (PNHs) are malformations of cortical development (MCD) related to neuronal migration disorders, frequently associated with drug-resistant epilepsy (DRE). Although magnetic resonance imaging (MRI) can clearly define the morphological features of PNHs, it still remains unclear whether the metabolic activity of ectopic neurons may correlate with neurologic symptoms. The aims of our study were to compare the diagnostic performance of 18F-FDG PET/CT compared to MRI, to assess the metabolic activity of the epileptogenic foci and to evaluate the clinical and prognostic value of PET findings. **Subjects and Methods:** Fifteen patients (8 men and 7 women; age range, 23-52 years) diagnosed with PNHs-related DRE were retrospectively evaluated from a single-centre database. All underwent clinical evaluation, Stereo-Electroencephalogram (SEEG), 1.5T 3D-brain MRI and 18F-FDG brain PET/CT. PET images were superimposed on the patient-specific 3D-brain-MRI to allow for a more accurate comparison. Metabolic activity was visually assessed and classified as normal (i.e. not significantly different from that of the surrounding structures), increased, reduced or absent. All the patients underwent surgical intervention either with radiofrequency thermocoagulation only (73.3%), conventional surgery only (6.7%) or both (20%). Outcome was assessed at ≥8-month follow-up (median 28 months). A favorable outcome was defined as reduced rate of seizures (Engel outcome 1A/B/C and 2A) and/or therapy reduction. **Results:** Four patients (26.7%) had unilateral PNHs localized in the right hemisphere, 3 unilateral in the left hemisphere and 8 (53.3%) had bilateral PNHs. MRI identified a total of 23 heterotopic sites. Of these, 10(43.5%) showed on PET a normal metabolic activity, 8(34.8%) were rated hypometabolic and in 5(21.7%) FDG metabolism was absent. PET allowed to identify other metabolic alterations outside the heterotopias, correlating with neurologcal symptoms. Specifically, a hypometabolism has been observed on the anterior mesial temporal region in 8 patients (53.3%) and on posterior temporal region in 2(13.3%). At follow-up, reduced rate of seizures was reported in 13 patients (86.7%), while therapy was reduced in 5 (33.3%). At univariate and multivariate analysis, the presence of hypometabolism or absent uptake in the heterotopic sites was significantly associated with a more favorable outcome (p=0.03). **Conclusions:** 18F-FDG PET identified 13 of 23 heterotopic sites identified by MRI (56.5%). However, more metabolic alterations were detected, correlating with neurological symptoms. Furthermore, hypo- or absent metabolism on PET can predict a more favorable outcome. Brain FDG PET provides important information on metabolic activity and allows to predict the outcome of surgical therapy.

Ultra-fast or Ultra-low Count Density Wholebody PET Imaging - Pushing the Envelope with Next-generation Digital PET

M. I. Knopp, J. Zhang, K. Binzel, R. Moore, M. Friel, C. L. Wright, M. V. Knopp; The Ohio State University, Columbus, OH, UNITED STATES OF AMERICA.

Purpose/Introduction: Improving acquisition speed has been essential developments in CT and MRI to improve image quality, patient comfort and reduce artifacts. Currently most PET acquisitions are performed between 90-120 seconds per bed position. Within a clinical development program to assess next generation digital PET imaging, this study was designed to approach reduction in imaging time not via incremental improvements but instead to use a moon shot approach by attempting to accomplish 10 X improvement. While 10 X didn't appear to be feasible at the onset, it was designed to better understand boundary conditions and to accelerate the development of new pet imaging approaches. **Subjects & Methods:** A next generation, digital photon counting PET/CT system was available (Vereos, Philips), (dPET) within a clinical development program that performed whole body FDG PET scans for oncologic applications. 25 patients were included in this add on study, where we performed a 9s per bed position whole body scan immediately after performing the standard 90s scan. Patient received standard diagnostic doses of 440 MBq. Prior to performing 10 X scan time reduction on human patients, we performed the feasibility assessment using two preclinical canine subjects. An independent, blinded three reader panel was used to assess image quality, diagnostic confidence, artifacts and visual noise. Prior Phantom and preclinical assessment validated that reduction in scan time can be used as an analog for reduced count density that also directly relates to dose reduction. Different reader assessment scales were used. **Results:** 9s per bed position or < 3 min whole body acquisitions led to unexpected good image quality. While all cases were rated interpretable, 20/25 cases were rated to be diagnostically usable. As expected, all cases were rated to have more noise. 23/25 presented with exactly the same clinical findings as the 90s/20min whole body scans. Quantitative target lesion variability (SUVmax) was below 10%. Simulated 10x whole body scans were ranked equivalent to true 10x acquisitions. **Discussion/Conclusion:** The 10x reduction in scan time and count density led to most surprising good, even diagnostic, image quality using the previous optimized reconstruction approaches. SUVmax values were comparable. Listmode simulated images were found to be predictors of true reduced count acquisitions. These most encouraging findings indicate that the new generation of digital PET technology will enable ultra-fast (wholebody < 3min) or ultra-low dose imaging (FDG dose <50 MBq). These initial clinical findings will need to be further validated in larger trials

E-PW111

A Noise Smoothing Origin Ensemble Algorithm Based on Regional Filtering

K. Chuang[1], C. Chiang[1], H. Lin[2], Y. Ni[3]; [1]National Tsing-Hua University, Hsin-Chu, TAIWAN, [2]Chang Gung University/Chang Gung Memorial Hospital, Taoyuan, TAIWAN, [3]Institute of Nuclear Energy Research, Long-Tan, TAIWAN.

Aim: Origin ensemble (OE) image reconstruction algorithm is preferentially used for the reconstruction of unconventional geometrical image, e.g. in a Compton camera (CC) system. Due to the low count rate in such a system, the reconstructed image is noisy. In this study, a novel way to smooth out the noise in the OE algorithm is proposed. **Materials and Methods:** The OE algorithm is performed on the list-mode data. During the reconstruction, the algorithm stochastically modifies the current location of each detected event to a random new location (voxel) along the probable corresponding surface. The new event origin location is accepted or rejected depending on an acceptance ratio which is determined by the relative number of event origins in the voxels (event density) of the new and the old locations. Original OE technique uses single voxel to calculate the event density. In the proposed method, either the mean or median computed from the pixel values of data points within a square region centered on both the old and new locations were used to compute the event density for decision rule. A point source was used to gauge the recovery rate, point spread function, and convergence speed while a flangeless phantom cylinder with fillable thin-walled cylinders inserts (diameters: 8, 12, 16, and 25 mm; height: ~3.8 cm) were used to measure the image quality of the reconstruction. **Results:** Point source study indicates that the number of correctly assigned events increases faster with iteration number and reaches a higher plateau for the proposed OE than conventional OE algorithms. However, the profiles drawn along the point source show the edge blurring effects for both mean and median filters. The contrast recovery coefficient (CRC) and coefficients of variation (CV) measured on the flangeless phantom demonstrate significant improvement for the filtered OE algorithm. **Conclusion:** Compare to the conventional OE algorithm, the proposed methods have the advantages of: improved undersampling phenomenon, faster convergence, and smoother image. The additional computation cost of the filtering is minimum.

E-PW112

A Simultaneous Method for MRI-based Partial Volume Correction and Image Registration in Brain PET

M. Ibaraki, K. Matsubara, T. Kinoshita; Akita Research Institute of Brain and Blood Vessels, Akita, JAPAN.

Introduction: Partial volume effect due to limited spatial resolution is a critical problem especially for measuring PET signals in fine structure such as cerebral cortex (a few millimeters of cortical thickness). Although several MRI-based partial volume correction (MRI-PVC) methods have been proposed, extreme sensitivity to inaccuracy of PET-MR image registration ham-

pers clinical application. The aim of the study was to develop a simultaneous method for PVC and PET-MR image registration, that is PVC with optimized registration (PoR). **Methods:** The proposed PoR is as follows: 1) PET images are registered to individual MR images using SPM's coregister function with default setting. 2) Geometric transfer matrix method (GTM) is applied to the registered PET images, generating region-wise PV-corrected PET images (GTM-PET). 3) The GTM-PET images are smoothed with point spread function (PSF) representing effective PET resolution. The PET images (PV-uncorrected) are re-registered to the smoothed GTM-PET images. These steps (1 to 3) are repeated until the convergence. 4) Finally, region-based voxel-wise correction (RBV; Thomas BA, EJNMMI 2011) is applied to derive voxel-wise PV-corrected PET images (RBV-PET). Water PET images (^{15}O-H$_2$O) obtained from healthy volunteers for CBF study were analyzed (n = 17). Anatomical labels generated from T1-weighted MR images (MPRAGE) using FreeSurfer were merged into 16 volumes of interest (VOIs), which were subsequently used for PVC with Gaussian PSF of 7.5-mm FWHM. Regional mean and intraregional coefficient of variation (COV = SD/mean*100%) in each VOI were calculated for RBV-PET images with and without PoR. **Results:** In the visual assessment of RBV-PET images, cortical voxels with abnormally low or high values were observed due to the inaccuracy of image registration between PET and MR. Number of the abnormal voxels were greatly reduced after the application of PoR. The regional mean values were similar with and without PoR for all the cortical regions, and the differences were smaller than 10% (except for two cases). The intraregional COVs, however, were significantly smaller for RBV-PET images with PoR, 13%±1%, 12%±1%, 15%±1%, and 15%±1% respectively for frontal, parietal, temporal, and occipital cortex compared to intraregional COVs without PoR (18%±7%, 12%±2%, 20%±8%, and 17%±5%), indicating superiority in image uniformity for RBV-PET with PoR. **Conclusion:** The simultaneous method for MRI-based PVC and PET-MR image registration improves quality of voxel-wise PV-corrected PET images, and may facilitate the use of PVC in future clinical settings.

E-PW113

A lesion detection study to evaluate a weight-based dose protocol combined with Pixon Planar Processing for wholebody bone scans

N. Gunson[1], V. Militano[2], N. Ali[2], A. Spencer[2], M. J. Memmott[2], K. J. Saint[2], J. D. Thompson[3], I. S. Armstrong[2]; [1]Christie Hospital, Manchester, UNITED KINGDOM, [2]Central Manchester University Hospitals, Manchester, UNITED KINGDOM, [3]University of Salford, Manchester, UNITED KINGDOM.

Objectives: Weight-based administrations have been implemented successfully in nuclear medicine along with advanced processing methods, providing dose reduction in low-weight patients whilst maintaining the diagnostic quality of images. Guidance on weight-based administration of ^{99m}Tc-MDP for wholebody bone scanning is limited. UK guidance recommends a standard 600 MBq administration for all patients whilst

EANM state a range between 300 and 740 MBq. This study evaluates a weight-based administration of 7MBq/kg ^{99m}Tc-MDP for patients up to 85kg, combined with Siemens Enhanced Planar Processing (EPP). The work is a lesion detection study where ground truth of lesion location is known. **Method**: Anterior wholebody views from 50 bone scans for patients with body weight below 85kg, negative of metastases, were included in this work. All images were acquired on a Siemens Symbia 3 hours after injection of 600 MBq of ^{99m}Tc-MDP at a scan speed of 20 cm/minute using LEHR collimators. Lesions, mimicking those observed in breast and prostate cancer, were inserted in the images. Lesions were created by increasing pixel values in the areas of the axial skeleton according to a 2-dimensional Gaussian shape. 15 images had no lesions inserted while 1-4 lesions were inserted into the remaining 35 images. Each image was resampled to simulate 7MBq/kg activity administration. Both full-count (control) and weight-based resampled images were processed using EPP, resulting in 100 images in total. Images were presented blind to 6 observers, who were asked to locate lesions with an associated confidence score. An acceptance radius of 5 pixels for the true lesion locations was selected. The results from all observers were compared with the ground truth using a weighted Jackknife alternative free-response receiver-operating characteristic (wJAFROC) with the wJAFROC figure of merit (FOM) used to compare the two groups of images. **Results**: The wJAFROC FOMs for the weight-based resampled and control group were 0.670±0.052 and 0.699±0.056 respectively. No significant difference was observed in lesion detection between the weight-based resampled and control images. **Conclusion**: This work has demonstrated that there is no significant difference in lesion detection for patients administered a standard 600MBq or a weight-based 7MBq/kg protocol. This suggests that the weight-based administration protocol is very promising and should be considered for routine practice. In our bone scan patient population this will result in a reduction in dose to half of all patients. It will also reduce the amount of activity required by the centre.

E-PW114

Image Quantitation for LEHR-collimated Tc-99m-TRODAT-1 SPECT: An Experimental Study with Striatal Phantom

M. Wu[1], K. Lin[1], B. Hsu[2]; [1]Dept of Nuclear Medicine, MacKay Memorial Hospital, Taipei, TAIWAN, [2]Nuclear Science and Engineering Institute, University of Missouri-Columbia, Columbia, MO, UNITED STATES OF AMERICA.

Purpose: ^{99m}Tc-TRODAT-1 (TRODAT) single photon emission computed tomography (SPECT) with low-energy high-resolution (LEHR) collimation has been clinically utilized worldwide, but not yet fully investigated for its accuracy in measurement of dopamine transporter (DAT) indexes. We conducted an experimental phantom study to verify the capability of quantitative image reconstruction (QIR) associated with a method of partial volume correction (PVC) for image quantitation of LEHR-collimated TRODAT SPECT. **Methods:** A series of six line-up point sources filled with various activity concentrations of ^{99m}Tc-pertechnetate

were employed to determine image resolution (IR). Simulations of TRODAT uptakes ranging from normal to Parkinson's disease and Parkinsonism (PD/PM) in a striatal phantom were utilized to test the accuracy of DAT indexes, including specific binding ratio (SBR), SBR-symmetry (SBR-sym) and caudate-to-putamen ratio (CPR), using images reconstructed with filtered back-projection (LEHR-FBP) and QIR (LEHR-Q). DAT indexes from LEHR-Q images were further corrected with PVC coefficients derived from an exponential model of target-to-background (TB) ratio to recover absolute activity concentrations (AAC) (unit: kBq/ml) in striatal regions. **Results:** IR of LEHR-FBP was 13.48±0.37 mm and significantly improved to 6.71±0.22mm in LEHR-Q (all p<0.0001). From the analysis of linear regression, linear slopes (LS) of SBR and CPR regressed to true values were significantly higher in LEHR-Q (0.529-0.586, 0.399) than those of LEHR-FBP (0.362-0.366, 0.247), and further improved to (0.952-1.011, 0.927) with PVC (all p<0.0001, all R^2 >0.956). Post PVC, LS (0.952) and R^2 (0.988) of SBR-sym stayed close to unity (p=NS). LS and R^2 of AAC in caudate correlated with true values were (0.943-1.035, 0.970-0.984) and (0.963-0.974, 0.983-0.994) for putamen. Blend-Altman plots reveled only small bias to true values (caudate: 0.9-2.3; putamen: -2.1-10.5 kBq/ml). **Conclusions:** From the phantom study, DAT indexes measured from TRODAT SPECT with LEHR collimation can be significantly enhanced by QIR. Adding PVC additionally achieves to recover AAC close to true values in striatal regions.

E-PW115
Initial Experience with a New PET/CT System Using SiPM Detectors

S. Park, L. Baratto, N. Hatami, G. Davidzon, S. Srinivas, S. Gambhir, A. Iagaru; Stanford University Medical Center, Stanford, CA, UNITED STATES OF AMERICA.

Introduction: We installed the first worldwide of a new digital PET/CT system that brings together silicon photomultiplier (SiPM) technology with time-of-flight (TOF) and block sequential regularized expectation maximization (BSREM, Q.clear®). We report our initial clinical experience using the new Discovery Meaningful Insights (DMI) scanner and evaluate the image quality in comparison to standard PET/CT scanners with and without TOF capability. **Subjects & Methods:** Seventy-three patients were scanned first on the standard of care PET/CT followed immediately by a scan on the new Digital PET/CT system using the same scan time per field of view. Images from the Digital PET/CT were reconstructed using a conventional (non-TOF) algorithm, TOF alone and TOF in combination with Q.clear®. Images from the standard of care PET/CT were reconstructed using clinical standard of care settings. Three blinded readers randomly reviewed four datasets per patient for image quality using a 5-point Likert scale: Standard of Care, $DMI_{non-TOF}$, DMI_{TOF} and $DMI_{TOF+Q.Clear}$. Standardized uptake value (SUV) measurements for the single most avid lesion on each dataset were also recorded. **Results:** In this side-by-side comparison, datasets from the DMI showed higher image quality (*P*<0.001) and SUV measurements compared with the standard of care

systems. Scores were further improved when TOF and Q.Clear® algorithms were added for image reconstruction. Of clinical interest, nine patients demonstrated lesions that could only be visualized on images from the DMI. Noticeably less respiratory artifacts at the diaphragm were also reported in the TOF-reconstructed images. **Conclusion:** The new Digital PET/CT system outperforms the standard of care scanners in terms of image quality, with further benefits added by the use of TOF and Q.Clear® reconstruction algorithms. This may be most beneficial in detecting small tumor lesions and for more accurate disease staging.

E-PW116
Improvements of game-theoretical image segmentation algorithm using PVE correction for nuclear medicine imaging

D. Borys[1], K. Szczucka-Borys[2], I. Gorczewska[3], A. d'Amico[3]; [1]Institute of Automatic Control, Silesian University of Technology, Gliwice, POLAND, [2]Department of Nuclear Medicine and Endocrine Oncology, Maria Sklodowska-Curie Memorial Cancer Center and Institute of Oncology, Gliwice Branch, Gliwice, POLAND, [3]Department of PET Diagnostics, Maria Sklodowska-Curie Memorial Cancer Center and Institute of Oncology, Gliwice Branch, Gliwice, POLAND.

Aim: In previous studies, our group tested different nuclear medicine images segmentation algorithms [1,2]. Tests showed that game-theoretical based algorithm presents the best performance using the Jaccard Index (JI). The aim of this studies was to improve the effectiveness of the algorithm using the Partial Volume Effect (PVE) correction technique and testing different methods of distance metrics in the algorithm. **Materials and Methods:** Data has been obtained using Siemens Biograph PET/CT. The phantom used in tests was a standard cylinder with five spheres of different radius and volume (diameter from 1.3 cm up to 4 cm) filled with a constant concentration of F-18-FDG. For the PVE correction, point source measurements have been done in six different localisations in the field of view (0 to 20 cm from the center) to estimate point source response variability. The algorithm, introduced by M.Pellilo was used for segmentation purpose [3]. The main idea was to represent the image as an edge-weighted graph, where vertices correspond to pixels, and their weights reflect similarity between them. The clustering algorithm uses replicator dynamics. Allocated pixels are removed from the graph and the process is repeated until all pixels are assigned to corresponding clusters. Weights of the edges have been calculated in different ways: using intensity only, intensity and the geometrical distance metric, the neighborhood information. -The measurements of the point source response allowed to estimate Gaussian function parameters in different locations for the PVE correction. It was used in the deconvolution-based algorithm for PVE correction. Results of segmentation were compared to CT image based reference mask by using a JI, which has range [0,1] where the value one corresponds to the full similarity of sets. **Results:** Methods for weights calculation other than intensity based were much less precise producing

visually inappropriate results that gave lower JI comparing to the first method (0.2 to 0.65). The JI improved from 0.65 to 0.79 when the PVE correction was taken into account. **Conclusion:** The method based on intensity measurements was the most effective for the algorithm used in this study. PVE correction improves results of the segmentation, especially for small objects allowing to classify correctly small structures. Acknowledgment: Grant No. STRATEGMED2/267398/4/NCBR/2015. Large bed overlap and short acquisition time or vice versa?

T. Andersen, P. Braad, P. Hoilund-Carlsen; Odense University Hospital, Odense, DENMARK.

Purpose: The reconstruction and data acquisition in 3D PET requires an overlap between each other following bed positions to compensate for low sensitivities in the field of view (FOV) edges when data are collected in a step-and-shoot acquisition mode. A small overlap between bed positions facilitates a larger throughput, i.e. larger scan length per unit time enabling full body scans in approximately 10 min. or shorter. Such scans hence enable fast whole body scans but at the cost of an uneven sensitivity profile across bed positions due to the triangular sensitivity profile of PET scanners along the scanner axis. In the current work the noise profile and quantitative accuracy were evaluated to determine the effect of bed overlap on image quality and to determine the optimal compromise between bed overlap and acquisition time per frame. **Methods:** A NEMA IQ phantom and a custom-made 55 cm long cylindrical tube with a diameter of 5.5 cm were scanned on a digital GE Discovery MI scanner with a 20 cm field of view. The phantoms were filled with a start activity of 5 kBq/cc of ^{18}F-FDG to mimic clinical relevant activity concentrations. Five series were acquired on the scanner with overlaps ranging from 15% to 50% in list mode acquisition. The acquired data were subsequently rebinned in frames ranging from 10 s. to 10 min. per bed position and reconstructed both with a standard 17/3 OSEM reconstruction with TOF and PSF applied and a Bayesian penalized likelihood reconstruction algorithm. Noise characteristics and quantitative accuracy were evaluated in 5 ROIs distributed in each slice of the phantoms as a function of slice position along the scanner axis. **Results:** Both the standard deviation of the voxel values, i.e. the noise, and the quantitative variation along the phantom length increased with smaller bed overlaps compared to larger overlaps. This was especially evident in short acquisition frames, i.e. time per bed position < 30 s. Little effect was observed on reconstruction method where both noise variation and quantitation accuracy were similar**. Conclusion:** The results suggest that large bed overlap and shorter acquisition time pr. bed position is advantageous compared to low bed overlap and longer acquisition time pr. bed position. The effect is especially evident in low count studies as for instance dosimetry scans with ^{124}I prior to ^{131}I therapy.

Optimal quantitative SUV metrics over wide range of lesion sizes in advanced image reconstruction (TOF and PSF) for PET

I. Shiri[1], P. Ghafarian[2,3], S. Ashrafinia[4], A. Bitarafan-Rajabi[1,5], M. AY[6,7], A. Rahmim[8,4]; [1]Department of Medical Physics, School of Medicine, Iran University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF, [2]Chronic Respiratory Diseases Research Center, National Research Institute of Tuberculosis and Lung Diseases (NRITLD), Shahid Beheshti University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF, [3]PET/CT and Cyclotron Center, Masih Daneshvari Hospital, Shahid Beheshti University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF, [4]Department of Electrical and Computer Engineering, Johns Hopkins University, Baltimore, MD, UNITED STATES OF AMERICA, [5]Cardiovascular Intervention Research Center, Rajaie Cardiovascular Medical and Research Center, Iran University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF, [6]Research Center for Molecular and Cellular Imaging, Tehran University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF, [7]Department of Medical Physics, School of Medicine, Tehran University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF, [8]Department of Radiology, Johns Hopkins University, Baltimore, MD, UNITED STATES OF AMERICA.

Aim: Tumor quantification using 18F-FDG PET has significant impact on routine usage in treatment response assessment and for prognostication in cancer patient. Advanced image reconstruction techniques available in routine PET imaging lead to improved image quality and lesion detectability; yet their quantification accuracy remains a topic of debate. The aim of this study was to evaluate the accuracy of quantification metrics over these reconstruction methods, and to find the most accurate SUV quantification metric in a wide range of lesion sizes. **Material and Methods**: The NEMA-IEC body phantom was used, consisting of six standard spheres (10 to 37mm) and small lesions (2, 3,4,5,6 and 7 mm) with different contrasts (4:1,2:1) and background activities, acquired in 3D list-mode for 5 minutes-per-bed position. Images were reconstructed using 3D-OSEM algorithm with and TOF and whit PSF-modeling. Quantification of each lesion VOI was performed using SUVmean, SUV42, SUV50, SUV70, SUVNestle, SUVmax, SUVpeak1cc and SUVpeak0.5cc. Subsequently, we determined Relative Errors (RE%) with respect to true SUV values for each metric. **Result:** In spheres larger than 13mm in diameter, SUVmax, SUVpeak0.5cc and SUVpeak1cc yielded significant overestimation (RE% of 44.8, 40.1 and 37.5 respectively). SUV50 was the only quantitative metric which had no statistically significant difference with respect to the true value in sphere (RE% of 11.77 to 0.44). In the 13 and 10 mm spheres, the best quantitative performance was obtained by SUVmax and SUVpeak0.5cc. Also, in spheres smaller than 10mm, all quantification metrics had significant underestimation and high relative error (-76.32 to -34.49). **Conclusion:** Our phantom study showed that optimal quantification of the 18F-FDG tracer in PSF- and TOF-enabled reconstruction is size dependent. Even including PSF and TOF, quantification in spheres smaller than 10mm in diameter is underestimated. It is

important to also point out that incorporation of PSF and TOF in the reconstruction leads to overestimation in larger sphere for certain SUV metrics and as such, can lead to incorrect assessment of treatment response. Therefore, more caution should be exercised when using SUV metrics in the context of new PET reconstruction techniques.

A demonstration of the concept of numerical twins in esophageal cancer patients

F. Orlhac[1], C. Nioche[1], S. Boughdad[1,2], M. Soussan[1,3], I. Buvat[1]; [1]IMIV, CEA, Inserm, CNRS, Univ. Paris-Sud, Université Paris-Saclay, CEA-SHFJ, Orsay, FRANCE, [2]Department of Nuclear Medicine, Institut Curie – René Huguenin, Saint-Cloud, FRANCE, [3]Department of Nuclear Medicine, Assistance Publique - Hôpitaux de Paris, Avicenne Hospital, Bobigny, FRANCE.

Purpose: The characterization of tumor heterogeneity using textural features in radiomic analyses of PET images has shown promise to predict patient response or survival. In this context, the goal of this study is to identify for each patient a radiomic numerical twin who has similar radiomic feature values to learn from the numerical twin's history and guide patient management. Here, we test this concept to predict treatment response.
Subjects & Methods: 107 patients with newly diagnosed esophageal cancer underwent pre-treatment 18F-FDG PET scan (data extracted from Ypsilantis et al, PLoS ONE 10(9):e0137036). All patients received a neoadjuvant chemotherapy and were later classified as non-responders (NR=69) or responders (R=38). In each patient, the primary lesion in the baseline scan was segmented using a threshold set to 40% of SUVmax. In each resulting volume of interest, 103 radiomic features were extracted including 85 textural or fractal features and 18 histogram indices. Each lesion was associated with a vector b of biomarkers. We computed the element-wise ratio between the vector $b(p)$ of one patient p and the vector $b(i)$ of each of the other 106 patients i (i=1,P-1). A patient N was identified as the radiomic numerical twin of patient p if the distance of $b(p)/b(N)$ to 1 was the lowest among the P-1 distances. Its response to treatment was then predicted as the one observed in patient N. We evaluated the ability of this approach to predict treatment response when using 2 or 3 biomarkers in b by calculating the Youden index in a leave-one-out validation. We compared the results with logistic regression and support vector machine (SVM) models.
Results: When including two biomarkers in b, the best performance using the numerical twin concept was obtained using Kurtosis and Energy with 87% NR lesions and 63.2% R lesions accurately classified (Youden=0.50). With three biomarkers (Kurtosis, Energy and Fractal Dimension mean), Youden index increased to 0.55. With 2 or 3 biomarkers, the logistic regression and SVM models always yielded Youden index less than 0.43. **Conclusion**: This concept of radiomic numerical twins is validated in esophageal cancer to predict treatment response. We found that lesions with similar radiomic profiles consisting of only 2 to 3 biomarkers had similar response to therapy. The identification of numerical twins could assist patient manage-

ment in the future, based on the disease evolution in the patients used to identify the numerical twin.

Conventional and microfluidic PET tracer synthesis on a novel synthesizer platform

C. Rensch[1], C. Frank[1], R. Salvamoser[1], G. Winter[1], S. Lindner[2], P. Bartenstein[2], F. Rensei[3], A. Hienzsch[4], R. Hesse[4], H. Lankau[4], M. Müller[4], A. Hoepping[4], V. Samper[1]; [1]GE Global Research, Garching near Munich, GERMANY, [2]Department of Nuclear Medicine, University Hospital Munich LMU, Munich, GERMANY, [3]GE Healthcare, Uppsala, SWEDEN, [4]ABX advanced biochemical compounds GmbH, Radeberg, GERMANY.

Introduction: Mini- and micro-scale technologies for PET tracer synthesis have been explored for more than two decades, as they hold the promise of reducing costs and improving synthesizer performance. Systems attempting downscaling of a process from an established baseline, or upscaling from exploratory studies, have encountered challenges such as spanning the different reagent volumes required, high cost of specialized components, or limited applicability to cGMP compliant routine production. The system presented overcomes these challenges. **Methods:** The core of the synthesizer is a consumable consisting of 1) a fluidic chip and 2) a reagent carrier. The chip is manufactured from a cyclic olefin co-polymer (COC) resistant to temperatures and chemicals commonly utilized in PET radiochemistry. The chip contains reactors, azeotropic dryers, pumps, and 70 individually addressable valves. All on-chip features can be routed by minor modifications of a standardized injection molded design, enabling large design flexibility at low cost. The routing channel sizes can be adapted from micro- to millimeters, enabling processing from microliter to milliliter volumes. This scalability is supported by a novel gas pressure driven fluid transport method that eliminates the need for syringe pumps whilst providing a good volume accuracy vs. range relationship, as well as a path to cGMP compliant operation by sterile filtration of the driving gases. The reagent carrier contains conventional vials, solid phase extraction (SPE) cartridges and sterile filters, providing an interface to established reagent kits and components. **Results:** For reagent volumes of microliters, the synthesizer platform was applied to research on carbon-11 radiolabeling of amino acids (Hienzsch et al., poster 441, ISRS 2017, Dresden, Germany). For conventional processing (milliliters), the GE FASTlab FDG citrate process (benchmark: 70±4% n.d.c. yield in <25min) was reproduced on the system achieving up to 65% n.d.c. yield in <25min without optimization. The fluoride-18 input activities were successfully scaled from 200 MBq to 170 GBq. **Conclusion:** The platform is capable of established stop-flow and unconventional research oriented processes, providing access to micro and conventional domains. A perspective to cGMP compliant operation is maintained by a consumable approach, interfaces to established reagent & SPE kits, as well as sterile filtration of the driving gases without use of syringes and associated tubing. Results show that this system can become a vehicle to bridge advanced synthesis design to routine production on a single platform. **Acknowledgements:** The authors gratefully acknowledge the financial support from the German Federal Ministry of Education and Research.

The Influence of Crystal Material and Size on the Sensitivity of Recently Developed SiPM Based Animal PET Scanner: a Monte Carlo Study

P. Ghahramani[1,2], N. Zeraatkar[2], N. Vosoughi[1], M. R. Ay[2,3]; [1]Radiation Medicine Engineering Department, Sharif University of Technology, Tehran, IRAN, ISLAMIC REPUBLIC OF, [2]Research Center for Molecular and Cellular Imaging, Tehran University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF, [3]Department of Medical Physics and Biomedical Engineering, Tehran University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF.

Aim: In this study, the sensitivity of an animal PET system by evaluating the influence of crystal material and size using Monte Carlo method has been optimized based on NEMA NU 4-2008 standards. **Materials and Methods:** An animal PET system with pixelated crystal has been recently designed and developed in our department. The ring diameter in the current version is 162 mm consisting of 10 modules. The sensitivity of system was evaluated for three commercial crystal materials including BGO, LYSO and GSO read out by SiPM, also for a range of crystal thicknesses (10-15 mm, 1 mm step), and for different crystal pixel sizes (1.4×1.4 - 2.2×2.2 mm^2, 0.2 mm^2 step). Each crystal block has 0.1 mm BaSO$_4$ as inner-pixel crystal reflectors. The axial field-of-view (AFOV) and energy window for all configurations respectively were 4.8 cm and 350-650 keV. The NEMA NU 4-2008 standards were used for evaluating sensitivity. According to NU-4, a ^{22}Na point source must be stepped from the beginning of the AFOV to the end of it with steps equal to slice thickness (45 steps for our system) and data should be acquired in each step. As the Monte Carlo method is slow and outputs are large, so we applied two approximations regarding to our symmetric geometry: we stepped the source in half AFOV and we increased the step length twice the NU-4. The system was well defined in the GATE Monte Carlo code in details. **Results:** For one configuration (LYSO crystal material, 10mm crystal thickness, 2×2 mm^2 crystal pixel size), the sensitivity based on NU-4 main method and after applying two approximations was respectively 1.42% and 1.45% representing 2% error due to the approximations while 75% time and volume of calculations were reduced. The sensitivity for BGO, LYSO and GSO was respectively 2.17%, 1.45%, and 0.92%. The sensitivity for 10, 11, 12, 13, 14, and 15 mm crystal thicknesses was respectively 1.45, 1.67, 1.89, 2.12, 2.35, and 2.57% and for 1.4×1.4, 1.6×1.6, 1.8×1.8, 2×2, and 2.2×2.2 mm^2 crystal pixel sizes was respectively 1.30,

1.32, 1.35, 1.45, and 1.47%. **Conclusion:** Based on the Monte Carlo results, BGO-based scanners have highest sensitivity and sensitivity of LYSO is more than GSO. By increasing the crystal thickness, sensitivity of the scanner increases due to its higher stopping power for 511 keV photons. The sensitivity also increases by increasing crystal pixel size because more photons can be detected.

EP-0003

Monte Carlo Based Performance estimation of breast PET scanners due to reduction of the ring diameter

A. Emami[1,2,3], *H. Ghadiri*[1,2], *P. Ghafarian*[4,5], *M. Ay*[1,2]; *[1]Research Center for Molecular and Cellular Imaging, Tehran University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF, [2]Department of Medical Physics and Biomedical Engineering, Tehran University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF, [3]International Campus, Tehran University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF, [4]Chronic Respiratory Diseases Research Center, National Research Institute of Tuberculosis and Lung Diseases (NRITLD), Shahid Beheshti University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF, [5]PET/CT and Cyclotron Center, Masih Daneshvari Hospital, Shahid Beheshti University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF.*

Aim: Positron emission tomography (PET) is a useful technique to visualize biologic processes within body before or during treatment. Breast PET imaging methods continue to evolve and have been improving the limitation of the sensitivity and spatial resolution of whole body scanners. The new designs of instrumentation have vastly progressed over the past ten years. An ideal system would with high sensitivity, spatial resolution, and low cost of scanner. **Materials and methods:** We have used computer simulations to compare three designs for a breast PET scanner with different ring diameters. In three systems rings are consist of 8, 9 and 10 LYSO modules, with transaxial field of view (FOV) of 128 mm,145 mm and 162 mm. The new designs combine high spatial resolution, and sensitivity to detect small, low-contrast masses. To measure spatial resolution and sensitivity we simulated point sources in the center of the imaging FOV, where the effects of axial parallax are largest. **Results**: We developed a prototype PET scanner that can achieve a spatial resolution and sensitivity approaching the physical limits of a small-bore scanner. The simulation results showed that FOV 162 mm has better sensitivity and spatial. Based on NEMA NU 4-2008 test, the comparison between different systems indicates that the absolute sensitivity of our system is %1.42 that is appropriate that others. The sensitivity is not highlight but decreasing AFOV including some advantages such as reducing the cost of scanner. Normalized sensitivity to AFOV is 0.29 that is extremely good in comparison with other commercial systems. **Conclusions:** The PET designs of the dedicated breast PET system has improved imaging characteristics in comparison to commercial whole-body scanners, particularly when special geometry scanner design. Also the number of detectors and related electronics are much less than others which reduces the cost.

EP-0004

Measurement of 225 ps CRT on 20 mm thick monolithic LYSO and CeBr3 crystals using Temporal imaging

C. Tata Zafiarifety[1], *A. Iltis*[1], *G. Zeufack Tadonkeng*[1], *L. Rodrigues*[1], *H. Snoussi*[2]; *[1]Damavan imaging, TROYES, FRANCE, [2]Université de Technologie de Troyes, TROYES, FRANCE.*

Promising performance for TOF-PET on pixelated LYSO or LaBr3 crystal has been obtained with Phillips Digital Si-PM. However the limited thickness of the crystal in those experiment is not compatible with the use in an actual PET scanner. Thick monolithic crystals would allow much higher detection efficiency. In this work we study the timing performance of 32x32x20 mm3 monolithic LYSO and 32x32x25 mm3 monolithic Cebr3 crystals. Here the 20 mm thick LYSO crystal has an intrinsic detection efficiency of 82.45 % for 511 KeV Gamma ray. We use Depth Of Interaction (DOI) positioning in the crystal to improve the timing performance. We are correcting the delay time introduced by the scintillation photon travelling the crystal at a speed of c/n, where n is the refractive index. Whereas gamma photon travels at the speed of light c. DOI is determined using the time arrival of the first photon and least mean square root method on simulated images. Measurements were performed using Na[22] source and LYSO crystals were wrapped with ESR Vikuity. Cebr3 crystals were wrapped with Teflon. Both were coupled to DPC3200 Si-PM. For LYSO crystal energy resolution of 10.1 % was obtained and coincidence resolving time (CRT) of 503 ps FWHM was measured without correction. When applying the correction of DOI time delay, the CRT was reduced to 225 ps FWHM. For CeBr3 the measurements are still ongoing and will be available shortly. This study shows that using thick monolithic crystals and a good DOI correction through temporal imaging, it is possible to obtain in a realistic configuration a good CRT for TOF-PET system.

EP-0005

Design and Development of a Small-Animal PET Scanner Based on Pixelated Crystals and Silicon Photomultipliers

M. Ay[1,2], *N. Zeraatkar*[1], *S. Sajedi*[1], *M. Taheri*[1], *S. Kaviani*[1], *S. Sarkar*[1,2]; *[1]Research Center for Molecular and Cellular Imaging, Tehran University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF, [2]Department of Medical Physics and Biomedical Engineering, Tehran University of Medical Sciences, Tehran, Iran, Tehran, IRAN, ISLAMIC REPUBLIC OF.*

Aim: During last two decades, the application of small animals in molecular imaging has been continuously increasing. Development of dedicated small-animal Positron Emission Tomography (PET) scanners, hence, underwent an ascending trend to provide the preclinical researchers with a molecular imaging scanner of higher spatial resolution and sensitivity to reach quantitative analysis ability. In this work, we introduce a new small-animal PET scanner called Xtrim, which we recently developed in our center. **Materials and Methods**: The Xtrim PET is a full-ring scanner composed of 10 detector blocks. Each block includes a 24x24 array of Lutetium-yttrium oxyorthosilicate (LYSO)

pixelated crystals attached to a 12x12 array of Silicon Photomultipliers (SiPMs). After pre-amplification and time-stamping, the data of all the blocks are transmitted to a main board. The main board is responsible for coincidence detection and sending the list-mode data to a computer. The axial field-of-view and bore opening of the scanner are respectively 50.3 mm and 120 mm. All calibration, correction, and data arrangement processes including positioning, energy calibration, normalization, rebinning, and image reconstruction are performed in the computer using an in-house software package. Some experiments were conducted to obtain preliminary performance parameters of the system. For this, spatial resolution and sensitivity of the system were examined using capillary and rod sources, respectively. Also, for evaluation of the animal imaging performance of the scanner, an F-18-sodium fluoride (NaF) scan using a rat was performed. **Results**: Spatial resolution of the system was measured as 1.8 mm at the center without resolution recovery. In addition, the sensitivity of the Xtrim was calculated as about 10%. The reconstructed images of the rat NaF scan revealed good imaging performance of the system resolving skeletal structure including acceptable resolutions for the vertebrae and the ribs. **Conclusion**: A dedicated small-animal PET scanner was designed and developed based on pixelated crystals and SiPM providing a potentially MR-compatible detection subsystem to be able to be merged with an MR modality and forming a PET/MR system. The preliminary performance evaluation of the system showed that Xtrim can be a reliable PET imager for numerous application in preclinical molecular imaging.

EP-0006

SiPM PET/CT vs. Standard PET/CT: A Pilot Study Comparing Semi-Quantitative Measurements in Normal Tissues and Lesions

L. Baratto[1], S. Park[1], N. Hatami[1], G. Davidzon[2], S. Srinivas[1], S. S. Gambhir[3], A. Iagaru[1]; [1]Stanford University, Division of Nuclear Medicine and Molecular Imaging, Department of Radiology, Stanford, CA, UNITED STATES OF AMERICA, [2]Stanford University, Radiological Sciences Laboratory, Stanford, CA, UNITED STATES OF AMERICA, [3]Stanford University School of Medicine, Departments of Radiology, Bioengineering, Materials Science and Engineering, Stanford, CA, UNITED STATES OF AMERICA.

Purpose: The aim of this pilot study is to determine if a new generation PET/CT scanner using silicon photomultipliers (SiPM), GE Discovery Molecular Insights - DMI PET/CT (GE Healthcare, Waukesha, WI), recently installed in our Department, provides equivalent results compared to the standard of care PET/CT scanners (GE Discovery 600 or GE Discovery 690) used in our clinic and to explore any possible differences in semi-quantitative measurements. **Materials and Methods:** We enrolled 50 patients who had a clinical indication for standard of care PET/CT. The local Institutional Review Board approved the protocol and written informed consent was obtained from each patient. All patients underwent a single injection dual imaging protocol including the standard of care PET/CT scan followed immediately by image acquisition using the DMI PET/CT scanner. We

measured SUV_{max} and SUV_{mean} of different background organs and up to 4 lesions per patient from data acquired using both scanners. **Results:** DMI PET/CT scan did not miss any of the 107 lesions detected by standard PET/CT scanners and identified additional 37 areas of focal ^{18}F-FDG uptake compatible with putative sites of disease. The results of equivalence tests on the normal tissues matched per patient showed an equivalence for all background tissues except for the cerebellum (*P* value < 0.01). The SUV_{max} measurements for all 107 lesions were 2.8 ± 2.8 higher on DMI PET/CT compared with standard of care PET/CT (*P* <0.0001) and this difference was not related to time delay between two scans (*P* <0.0001). Lesion:aortic arch ratios and lesion:liver ratios were 3.2 ± 2.6 and 1.9 ± 1.4 higher on DMI PET/CT compared with standard of care PET/CT (*P* <0.0001). **Conclusions:** The performance of SiPM PET/CT is at least comparable to that of standard PET/CT. While delayed imaging can lead to detection of additional lesions, our data suggests that in this series the lesions identified only on DMI PET/CT indicate superior performance of the scanner. Further evaluation needed to confirm our data. Differences in semi-quantitative measurements between standard PET/CT and SiPM PET/CT are important factors when adopting the new technology.

EP-0007

Optimization of the crystal thickness for a monolithic LYSO animal PET detector with anger and CSE positioning method using Monte Carlo simulation

A. Sanaat[1,2], M. Shamsaie[1], B. Teymorian[1], R. Hashemi[2,3], M. Ay[3,2]; [1]Department of Energy and Physics, AmirKabir University of Technology (Tehran Polytechnic), Tehran, IRAN, ISLAMIC REPUBLIC OF, [2]Research Center for Molecular and Cellular Imaging, Tehran University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF, [3]Department of Medical Physics and Biomedical Engineering, Tehran University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF.

Introduction: In nuclear medicine imaging systems' detectors, intrinsic spatial resolution and sensitivity depend on the identification and accuracy of an interacting point and the amount of interacting photons to sensitive cell. These factors is dominated by propagation of the scintillation photons in the detector crystal, positioning algorithm and physical features of the crystal. This study was intended to use Monte Carlo simulation to estimate the intrinsic spatial resolution and sensitivity of animal PET detector by using two positioning algorithm method. **Subjects & Methods:** We used Geant4 Monte Carlo simulation library to simulate the optical photon processes. Our simulation includes geometry of crystal, reflector, light guide and silicon photo multiplier SiPM and all the optical process. The validation of the simulation code was performed for a monolithic NaI(Tl) scintillator ($402 \times 246 \times 9.5$ mm³) coupled to 24 flat-panel type multi-anode photo multiplier tubes (PMT) (R6237: Hamamatsu) and results were compared with those obtained experimentally. Moreover, the code was applied to a LYSO scintillator with entrance area 50.2×50.2 mm² and various thicknesses (4 - 6 - 8 - 10 mm) coupled to a 12×12 SiPM (Sensl ArrayC-30035-144P-

PCB) for finding the best geometry and positioning algorithm. **Results:** Our simulation indicated 3.5 mm full width at half maximum (FWHM) of spatial resolution for the NaI(Tl) detector, which were in a good agreement with the experimental results. This investigation has shown that Geant4 simulation toolkit enables us to predict optical process accurately. Furthermore simulation of animal PET detector for a centric point source showed that the best resolution and sensitivity obtained in 6mm thickness (0.93 mm & 49%), also Anger and Correlated Signal Enhancement (CSE) algorithms positioning were tested and CSE algorithm showed better performance in edge and center positioning.(resolution in 25mm from center of the crystal by CSE method was calculated 31% lower than Anger). In this study the ratio of total number of scintillation photons to number of photons which are fire SiPM pixels are measured. This parameter start from 0.19% for 4mm thickness and decrease to 0.1% for 10mm thickness. **Conclusion:** The Geant4 simulation established to estimate the intrinsic spatial resolution and sensitivity of animal PET detector with Anger and CSE positioning algorithm and also different thickness. This simulation can be used to provide an optimal design of animal PET monolithic detector without physical experiment.

EP-0008

Performance Evaluation of a New High Resolution Non-human Primate (NHP) PET/CT System (LFER 150 PET/CT)

Z. Sarnyai[1], K. Nagy[2], G. Patay[2], M. Molnár[2], G. Rosenqvist[1], M. Tóth[1], A. Takano[1], B. Gulyás[1], C. Halldin[1], P. Major[2], A. Varrone[1]; [1]Karolinska Institutet, Stockholm, SWEDEN, [2]Mediso Ltd., Budapest, HUNGARY.

Aim: The LFER 150 PET/CT by Mediso is a high-resolution system for non-human primate (NHP) imaging. The objective of this study was to evaluate the performance of the system using the NEMA NU 4 standard protocol**. Materials and Methods:** The NEMA NU4 standard protocol was used for resolution, sensitivity, image quality (IQ) and noise equivalent count rate (NEC). NEC measurement was performed with the rat-like and the monkey-like phantom. A Derenzo phantom was acquired to test the resolution using 3D OSEM reconstruction. One cynomolgus monkey (4.5 kg, IV ketamine/xylazine anesthesia) was examined with the dopamine transporter radioligand [^{18}F] FE-PE2I (90 MBq) to evaluate the in vivo performance of the system. Attenuation correction was performed using a material map generated by segmentation of the CT image. List mode PET data acquired for 93 min were reconstructed into 38 frames with the Tera-Tomo™ 3D engine using OSEM algorithm. Binding potential (*BP*$_{ND}$) for caudate, putamen and substantia nigra were evaluated using the simplified reference tissue model. **Results:** Radial FWHM resolution using Fourier rebinning and 2D filtered back projection (FBP) algorithm was better than 2.2 mm and 3.2 mm in the central 60 mm and 160 mm diameter region, respectively. Maximum sensitivity in 400-600 keV and 250-750 keV energy window was 30.03 cps/kBq (3.3%) and 49.11 cps/kBq (5.4%) respectively. The uniformity in the IQ phantom was 3.3 % and the spill-over ratio for air and water was 0.1. The peak of the NEC curve was 399 kcps (149 MBq) using the rat-like phantom and

64.7 kcps (128 MBq) using the monkey-like phantom. Rods of the Derenzo phantom with 1 mm diameter could be visualised. In the NHP experiment *BP*$_{ND}$ values in the caudate, putamen and substantia nigra (4.31, 4.45 and 0.7 respectively) were similar to those previously reported in NHPs using the same radioligand and the high-resolution research tomography. **Conclusion:** The results obtained from phantom experiments and one representative PET measurement in NHP confirm that the LFER 150 is a high-resolution PET-CT system with suitable performance for brain imaging in NHPs.

EP-0009

Design optimization of partial cylindrical PET scanner based on trapezoid-shaped block detector and monolithic crystals using Monte Carlo simulation

P. Sheikhzadeh[1,2], H. Ghadiri[1,2], P. Geramifar[3], P. Ghaffarian[4,5], M. Ay[1,2]; [1]Department of Medical Physics and Biomedical Engineering, Tehran University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF, [2]Research Center for Molecular and Cellular Imaging, Tehran University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF, [3]Research Center for Nuclear Medicine, Shariati Hospital, Tehran University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF, [4]Chronic Respiratory Diseases Research Center, National Research Institute of Tuberculosis and Lung Diseases (NRITLD),Shahid Beheshti university of medical science, Tehran, IRAN, ISLAMIC REPUBLIC OF, [5]PET/CT and Cyclotron Center, Masih Daneshvari Hospital, Shahid Beheshti University of Medical Sciences,, Tehran, IRAN, ISLAMIC REPUBLIC OF.

Aim: Cylindrical PET geometries with the conventional detector blocks are subject to sensitivity loss due to inter-block gap between the rectangular detector blocks. The sensitivity loss is more pronounce with pixelated crystals that suffer from lower packing fraction due to inter-pixel reflectors. One potential solution is to use trapezoid detector blocks in combination with using monolithic crystals. The objective of this work is to compare system sensitivity of PET system designs with headphone-like geometry. Our headphone-like geometry design is in fact a cylinder-like geometry with partially populated detector blocks. In this work we methodically compare the sensitivity gain across the FOV when using monolithic trapezoid detector blocks with that of pixelated rectangular blocks. **Material and Methods:** GATE Monte Carlo toolkit was used to model the PET systems. In both designs, there are 22 detector blocks per ring. The ring diameter and axial length were kept the same at 245 mm and 277 mm, respectively. We used 30 mm thick BGO crystal in the detector blocks. Block cross-section is 25.2*25.2 mm^2 at the entrance side for both designs and 31.0*31.0 mm^2 at the exit side in the trapezoid detector blocks. The BGO crystals in the rectangular block are pixelated with 2.3 mm pixels. System sensitivity of two scanner designs were measured at the center and 7 cm offset from the center of the scanner using a point-like source. **Results:** System sensitivity of 20.01% and 28.91% was calculated at the FOV center and 7 cm off-center, respectively, for the design with trapezoid monolithic crystals. The calculated values for pixelated rectangular detector block were 17.34% and

25.59%. These values show ~ 15% sensitivity gain at the FOV center and 13% gain at 7cm off-center for a point-like source. **Conclusion:** Our results show that by simply using monolithic trapezoid crystals instead of pixelated rectangular crystals we can gain ~ 15%. It is noteworthy that monolithic crystals even in trapezoid shape are cheaper to manufacture compared with pixelated arrays. The higher system sensitivity can also be used to reduce the administered patient dose or to shortening the acquisition time.

EP-0010

Feasibility of Whole Body Dynamic Acquisitions using Digital PET/CT - A Preclinical Phase I Study

K. Binzel[1], J. Zhang[1], M. I. Menendez[1], M. Friel[1], M. I. Knopp[1], R. Moore[1], C. L. Wright[1], P. Maniawski[2], M. V. Knopp[1]; [1]The Ohio State University, Columbus, OH, UNITED STATES OF AMERICA, [2]Philips Healthcare, Cleveland, OH, UNITED STATES OF AMERICA.

Aim: The future of PET/CT imaging will undoubtedly include imaging agents, acquisitions and applications beyond our current scope, as new radiopharmaceuticals are developed for specific imaging of disease states well beyond oncology and the benefit of dynamic imaging has become more evident. We explored the feasibility of performing whole body dynamic imaging enabled by the advantages provided by next-generation digital photon counting PET technology. **Materials and Methods:** We performed preclinical imaging on a pre-commercial release next-generation digital PET/CT system (Philips Vereos, dPET). dPET enables count sensitivity superior to conventional imaging systems with time of flight timing resolution of 325 ps. The potential for ultra-fast imaging protocols is being demonstrated in other preclinical as well as clinical work. We developed a feasibility study in healthy canines utilizing 10s per bed acquisitions covering a series of positions from head to pelvis, repeated up to 15 times, with imaging starting at the time of injection. From these repeated acquisitions, time activity curves or other dynamic data analysis can be generated over an area greater than the single volume dynamic field of view traditionally employed. **Results:** We found that this whole body imaging approach is readily feasible after protocol development and fine tuning performed over our first several imaging sessions. There can be different approaches such as head to feet cycling which will ensure the same temporal resolution for all locations versus head-to-feet-to-head cycling leading to varying time-lapse periods. We also found that a slower, non-bolus injection can lead to excellent imaging of the vascular phase. System performance must be fine-tuned to minimize any data transfer delays. This acquisition approach is quite strenuous from a system performance point of view. Even with cycle times of 1 - 2 min, we found that tracer uptake curves can be readily generated from any desired body region. The ultra-short acquisition time requires count sparsity optimized image reconstruction that should be regularized for relative count densities. **Conclusion:** Next-generation digital PET/CT provides a leap in technology that enables ultra-short PET acquisitions which can be expanded to whole body dynamic acquisition protocols. Performing repeated, ultra-fast acquisitions of a large volume / whole body from the time of radiotracer injection can provide insight into the biodistribution not previously possible when limited to a single bed field of view. With the development of new radiotracers for applications beyond oncology, such an imaging approach appears to be extremely valuable.

EP-0011

Accuracy and precision of activity concentration measurements for GE Q.Metrix absolute SPECT quantification

I. Armstrong; Central Manchester University Hospitals, Manchester, UNITED KINGDOM.

Aims: Absolute quantification packages to offer "SUV SPECT" are now available from several vendors. There are currently very few technical assessments of SUV SPECT to evaluate the accuracy and precision of metrics from images. This phantom work evaluates this using GE Q.Metrix. **Method:** SPECT/CT of NEMA image quality and anthropomorphic cardiac torso phantoms were acquired on a GE Optima 640 with LEHR collimators. Studies were ECG-gated with an external trigger to provide 8 replicate images. Total counts in each replicate were 12×10^6 and 2.3×10^6 for the NEMA and torso respectively. NEMA scans were performed with 5:1 and 10:1 sphere contrast and 3-degree and 6-degree projection steps. Images were reconstructed with corrections for attenuation, scatter and resolution using GE default parameters (4 iterations, 10 subsets, no post-filter). Maximum voxel and region mean activity concentration recovery (ACR) (ratio of measured to true) was calculated in the four largest NEMA spheres (VOIs defined on CT) and cardiac insert (40% maximum voxel threshold VOI on SPECT). Mean and standard deviation of ACR were calculated across replicates. **Results:** Maximum ACR in the NEMA spheres (37, 28, 22, 17mm respectively) was 1.33±0.03, 1.31±0.06, 0.91±0.08 and 0.53±0.07 for 5:1 contrast and 3-degree projections; 1.43±0.06, 1.39±0.10, 0.99±0.10 and 0.57±0.06 for 5:1 contrast and 6-degree projections; 1.35±0.05, 1.32±0.05, 1.21±0.07 and 0.62±0.03 for 10:1 contrast and 3-degree projections; 1.37±0.05, 1.36±0.07, 1.22±0.05 and 0.67±0.03 for 10:1 contrast and 6-degree projections. Mean ACR in the NEMA spheres was 0.89±0.01, 0.80±0.02, 0.61±0.02 and 0.44±0.05 for 5:1 contrast and 3-degree projections; 0.90±0.01, 0.82±0.03, 0.63±0.03 and 0.46±0.04 for 5:1 contrast and 6-degree projections; 0.87±0.01, 0.82±0.01, 0.68±0.03 and 0.44±0.02 for 10:1 contrast and 3-degree projections; 0.88±0.01, 0.82±0.02, 0.68±0.02 and 0.47±0.01 for 10:1 contrast and 6-degree projections. Maximum and mean ACR in the cardiac insert was 1.22±0.05 and 0.65±0.01. **Conclusions:** Positive bias is seen in maximum voxel measures in both NEMA spheres and the cardiac insert. Accuracy is good in the largest two spheres at both

contrasts with ACR>80% for mean measurements. Percentage variability for the NEMA spheres is very good (<6.0% for 10:1; <13% for 5:1) and also in the cardiac insert (2% for mean measurements). NEMA data suggests that 6-degree projections may provide marginally superior ACR, particularly as object contrast is reduced. The work also demonstrates marked ACR reductions due to partial volume effects for objects approximately 2 cm or smaller in size.

EP-0012

Impact of Point-Spread Function on the Image Quality in Small-Voxel Reconstructions of ^{18}F-FDG-PET Images

N. Assink[1,2], J. A. van Dalen[3], D. Koopman[1,2], H. Stevens[1], C. H. Slump[2], P. L. Jager[1]; [1]Department of Nuclear Medicine, Isala, Zwolle, NETHERLANDS, [2]MIRA Institute for Biomedical Technology and Technical Medicine, University of Twente, Enschede, NETHERLANDS, [3]Department of Medical Physics, Isala, Zwolle, NETHERLANDS.

Introduction: Point-spread function (PSF) modelling is an image optimization method that can partly compensate for resolution degrading effects in FDG-PET imaging. Several studies have evaluated the impact of PSF modelling as part of the image reconstruction. However, PSF modelling can also be applied as a post-reconstruction deconvolution. We have investigated the effect of this type of PSF modelling on the image quality of FDG-PET. **Subjects and Methods:** We first evaluated FDG-PET images of a NEMA image quality phantom containing 6 spheres (diameter 10-37 mm) with a sphere-to-background ratio of 4:1. Data were acquired with the Ingenuity TF PET/CT-scanner (Philips) and iteratively reconstructed using 2x2x2 mm^3 voxels and various PSF settings (1-10 iterations and 2-20 mm regularization). We determined the mean and maximum contrast recovery coefficients (CRC$_{mean}$ and CRC$_{max}$) of the spheres and the noise (standard deviation) in a homogeneous region in the background. Optimized PSF settings were derived by selecting the reconstruction with the highest CRCs without enhancing noise. This reconstruction was compared with a non-PSF reconstruction. Secondly, we included 22 oncology patients with 38 FDG-PET positive lesions varying in size and origin. Image reconstructions using previously determined PSF settings were compared to those without PSF. All lesions' mean and maximum standardized uptake values (SUV$_{mean}$ and SUV$_{max}$) were determined and the noise was measured in a homogeneous region in the liver. Furthermore, two expert readers visually assessed the image quality by a blind and randomised comparison of non-PSF and PSF images. **Results:** Optimized PSF settings were 1 iteration and 8 mm regularization, resulting in enhanced CRC$_{mean}$ and CRC$_{max}$ up to 38% and 32%, respectively. The increase in noise was kept to 3%. On patient data, PSF images resulted in enhanced SUV$_{mean}$ and SUV$_{max}$ in all lesions (mean diameter 16 mm, range 8-36 mm) with an average increase of 27% and 26%, respectively. Yet, noise increased with 11%. Visual analysis showed a preference towards the non-PSF reconstruction in 68% of the cases, although differences were considered subtle. **Conclusion:** PSF modelling as a post-recon-

struction deconvolution can be used to enhance lesions' SUV with a limited noise increase. Meanwhile, first experience by experts shows a preference towards non-PSF images, possibly because in our study all lesions could already be identified in these images.

EP-0013

A Comparison Study on Two Novel Statistical Reconstruction Algorithms Developed for Slit-Hole Collimation Data in Small Animal SPECT Imaging

H. Mahani[1,2], G. Raisali[1], A. Kamali-Asl[3], M. Ay[2,4]; [1]Nuclear Science and Technology Research Institute (NSTRI), Tehran, IRAN, ISLAMIC REPUBLIC OF, [2]Research Center for Molecular and Cellular Imaging, Tehran University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF, [3]Radiation Medicine Engineering Department, Shahid Beheshti University, Tehran, IRAN, ISLAMIC REPUBLIC OF, [4]Department of Medical Physics and Biomedical Engineering, Tehran University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF.

Aim: Slit-hole collimator offers simulations a high-resolution and high-sensitivity SPECT camera and measures planar projections of the object being imaged. Given the special geometry and the sophisticated imaging protocol associated with this collimator, developing novel image reconstruction techniques is mandatory. In the current research, we are aiming at comparing two innovative fully 3D in-house iterative reconstruction algorithms based on planar integral data. **Methods**: In algorithm I, the convergent plane integrals were first rebinned into parallel planar integral format. The resorted data were then reconstructed by a rotation-based MLEM algorithm. Algorithm II directly deals with the convergent planar integrals, and uses a joint plane-driven/rotation-based projector. For both, location-dependent sensitivity was also modeled. To compare the performance of the two algorithms, a 3D digital noise-free Shepp-Logan phantom, a dedicated 5-point source phantom along with NEMA image quality (IQ) were reconstructed. A fair comparison was made by assessing normalized square error (NSE), tomographic resolution, and convergence rate. There were 16 spin angles and 16 SPECT angles for data acquisition. **Results**: The NSE for the Shepp-Logan phantom reconstruction is 13% and 9% for algorithm I and algorithm II, respectively. Algorithm I results in a tomographic resolution of 1.95 mm compared with a 1.7 mm tomographic resolution obtained using algorithm II. These tomographic resolutions are averaged for the 5 point sources. The SNR of the reconstructed image using algorithm I reaches its maximum value after 2 iterations, while 3 iterations are needed for obtaining the highest SNR using algorithm II. For the same 5% noise level in reconstructed uniform part of the NEMA IQ phantom, algorithm II requires approximately a two-fold reconstruction time per iteration compared with algorithm I. **Conclusion**: Although, the performances of both algorithms are promising for reconstruction of the convergent planar projection data, algorithm II leads to superior image quality characteristics than algorithm I, but the expense of both a slower convergence rate and a larger reconstruction burden.

EP-0014

Development of Monte Carlo Simulation Based Quantitative Image Reconstruction for SPECT/CT

K. Sakaguchi[1,2,3], S. Yoshida[1], S. Watanabe[1,2], K. Matano[1], M. Okumura[1], M. Hosono[4,2], K. Ishii[4,2], T. Murakami[4,2]; [1]Department of Radiology, Kindai University Hospital, Osaka, JAPAN, [2]Division of Positron Emission Tomography, Institute of Advanced Clinical Medicine, Faculty of Medicine, Kindai University, Osaka, JAPAN, [3]Laboratory of Radiation Biology, Department of Biological Science, Graduate School of Science, Osaka Prefecture University, Osaka, JAPAN, [4]Department of Radiology, Faculty of Medicine, Kindai University, Osaka, JAPAN.

Aim: Iterative reconstruction for SPECT is composed of 5 parts, forward projection, comparison, back projection, normalization, and update. The advantage of iterative reconstruction is that, since includes various physical phenomena such as scatter, attenuation, and depth-dependent blur into a probability density matrix of forward projection, images can be reconstructed with corrections corresponding to these physical phenomena. Iterative reconstruction usually provides qualitative images but not quantitative images because the probability matrix it adopts is usually an approximate matrix, instead of a matrix that fully deals with these physical phenomena. The purpose of this study was to develop a Monte-Carlo simulation based iterative reconstruction for obtaining quantitative reconstructed SPECT images, and to evaluate its accuracy with phantom studies. **Materials and Methods:** The SIMIND Monte-Carlo program has been widely used for simulation of various scintillation camera imaging. This program is able to output list-mode data in which emission point, detection point in the crystal, photon weight, and scatter order were recorded. Since this list-mode data can be used as a probability density matrix in forward projection, we crafted a Maximum Likelihood - Expectation Maximization algorithm in which the list-mode data was incorporated into the forward projection using C-language. And we evaluated the accuracy of the proposed method with two kinds of phantom studies. In the cylindrical phantom study, two cylindrical phantoms filled with technetium-99m solution (8030.48[Bq/ml] at mid scan time) and iodine-123 solution (9392.38[Bq/ml]) were measured using SPECT/CT. In the NEMA body phantom study, two NEMA body phantoms filled with technetium-99m solution (each sphere (Diameter: 37mm, 28mm, 22mm, 17mm, 13mm, and 10mm): 37466.29[Bq/ml], background: 7622.75[Bq/ml]) and iodine-123 solution (each sphere: 39949.21[Bq/ml], background: 8108.62[Bq/ml]) were measured. [Results] In the both cylindrical phantom studies, the voxel value of reconstructed images (Technetium-99m: 8052.90[Bq/ml], Iodine-123: 9828.08[Bq/ml]) indicated a good agreement with known radioactive concentration. In the NEMA body phantom filled with technetium-99m, the voxel value of 37mm sphere, 28mm sphere and background on reconstructed images showed 37163.91[Bq/ml], 36713.40[Bq/ml], and 7605.56[Bq/ml], respectively. In the NEMA body phantom filled with iodine-123, the voxel value of 37mm sphere, 28mm sphere and background on reconstructed images showed 39481.44[Bq/ml], 37930.51[Bq/ml], and 7872.69[Bq/ml], respectively. These voxel value of reconstructed images indicated a good agreement with known radioactive concentration. [Conclusions] Our proposed method was able to estimate radioactivity concentration for more than 28mm sphere with a high accuracy. Our method opens up new possibilities for quantitative nuclear medicine procedures including dosimetry in radionuclide therapy.

EP-0015

Evaluation of optimized iterative reconstruction parameters using channelized Hotelling observer in brain receptor PET imaging

K. Matsumoto[1], H. Ogawa[1], Y. Matsumoto[1], G. Akamatsu[2], M. Senda[2], K. Murase[3], K. Endo[1]; [1]Kyoto College Of Medical Science, Kyoto, JAPAN, [2]Institute of Biomedical Research and Innovation, Kobe, JAPAN, [3]Graduate School of Medicine, Osaka University, Osaka, JAPAN.

Aim: ^{18}F-FDOPA and ^{11}C-raclopride has drawn new attention as a biomarker of regenerative therapy for Parkinson's disease with implantation of dopaminergic cells (including iPS-derived ones) or infusion of drugs with regenerating effects into the striatum. Recently, iterative reconstruction began to be used in dopamine transmitter/receptor PET images and the ordered-subset expectation maximization (OSEM) algorithm was a method used widely in some iterative algorithms. In brain receptor PET imaging using high-resolution PET scanner, optimization of reconstruction parameters is essential because the image noise influences the diagnostic performance and quantitative accuracy. The purpose of this study was to evaluate optimal reconstruction parameters of the OSEM algorithm using the channelized Hotelling observer (CHO) well correlated with human observer. **Methods:** A PET/CT scanner, GE Healthcare Discovery 690, was used to scan image of a striatal phantom (Radiology Support Devices, Inc.). To evaluate the performance of the present method, we also carried out the computer simulations with the digital brain phantom. The OSEM parameters was changing the number of subsets and iterations. The CHO was applied to 50 slices from the images of each type to compute detectability index (d_{CHO}), and the optimum image reconstruction parameter was evaluated. In this study, the channel vector elements were taken as the integrated values of the two-dimensional Fourier-transformed image within pre-defined frequency bands (or channels), and the total number of channels was taken as 16 with an equal band width, i.e., Nyquist frequency/16. **Results:** The d_{CHO} value of simulation and PET became the maximum when approximately 50 iterative updates. As for the PET study, the d_{CHO} value became the maximum when the numbers of subsets and iterations were 12 and 4, respectively. **Conclusions:** Our preliminary data suggested that the CHO was effective in reconstruction parameters setting of the OSEM algorithm. Generally the optimum reconstruction parameters of the OSEM algorithm are dependent on the statistics noise of projection data, but optimum reconstruction parameters can be quantitatively evaluated using the CHO.

EP-0016

The Impact of a Penalized Likelihood Reconstruction Algorithm on the Quantitative Evaluation of Hepatic Metastases Shown on ^{18}F-FDG-PET/CT Studies - Preliminary Results

S. Czibor, Z. Varga, A. Fekésházy, L. Jorgov, B. Kári, B. Magyar, J. Török, G. Dabasi, T. Györke; *Semmelweis University, Nuclear Medicine Centre, Budapest, HUNGARY.*

Introduction: PET/CT scans are routinely reconstructed by iterative algorithms, where a well-known limitation is the worsening of the signal-to-noise ratio when increasing the number of iterations. A novel Bayesian penalized likelihood reconstruction algorithm (BPL) has allowed more iterations without simultaneously significantly increasing noise levels that results in a better signal-background ratio. The aim of our study was to compare this algorithm with the conventional OSEM reconstruction by investigating ^{18}F-FDG-PET/CT studies. **Methods:** We investigated the ^{18}F-FDG-PET/CT studies of 9 patients (6 women, 3 men) and a total of 24 FDG-avid hepatic metastases were included in our sample. The raw data of each patient were reconstructed by both the OSEM and the BPL algorithm. A spheric VOI of 3 cm diameter was placed in the normal hepatic tissue as reference and a spheric VOI was manually adjusted to the metastases, both in an identic location in the two differently reconstructed studies of each patient. The size of the lesions were calculated by the largest axial diamater measured on the CT scans. Standardized uptake values (SUV) based on body weight were calculated, including SUVmax and SUVmean. Noise was defined as the standard deviation of the normal liver parenchyma SUV. Signal-to-noise ratio was given as SUVmean in the normal liver parenchyma divided by the noise. Signal-to-background ratio was defined by SUVmax in a lesion divided by the SUVmean in the normal liver parenchyma. Two-tailed paired sample t-tests were calculated to compare the datasets. **Results:** The average size of the lesions was 18±8,85 mm (range: 10-53 mm). The BPL algorithm resulted in significantly higher SUVmax and SUVmean values in the lesions (P<0,001): ΔSUVmax 2,12±1,75; ΔSUVmean 0,50±0,48. The signal-to-background ratio was significantly better with BPL (3,33±2,45 vs. 2,87±2,26; p<0,001) while signal-to-noise and SUVmean-to-noise ratios were not significantly different. The latter can be explained with the (nonsignificantly) higher levels of noise by using BPL. **Conclusion:** Our study showed that the BPL reconstruction algorithm resulted in better signal-to-background ratios without the decrease of the signal-to-noise ratio in FDG-avid hepatic metastases which leads to better recognition and characterization of the lesions.

EP-0017

Evaluation of FDG PET/CT lesion detectability and quantification harmonization

J. Devriese[1], L. Beels[2], E. Deboever[1], B. Decru[1], A. Maes[2], C. Van de Wiele[2], H. Pottel[1]; [1]KU Leuven campus Kortrijk, Kortrijk, BELGIUM, [2]AZ Groeninge, Kortrijk, BELGIUM.

Introduction: Standardized uptake value (SUV) is a valuable tool in quantitative ^{18}F-FDG PET/CT imaging and is used in staging and therapy follow-up. In this context as well as multicentre studies it is essential that SUV is accurate and reproducible. There are multiple biological and technical factors that can introduce variability, and several guidelines have been published with recommendations to standardize PET/CT procedures in order to reduce variability. An important factor in the scan process is the PET reconstruction protocol. Standard clinical protocols are optimized for lesion detection and this often does not match the reconstruction protocol that fulfils EARL guidelines, launched by the EANM to promote multicentre nuclear medicine and research, optimized for harmonized quantitative imaging. Different vendors aim to combine lesion detectability and quantification in one reconstruction protocol. In this study one such solution is compared to the lesion detection and EARL protocol. **Subjects & Methods:** Clinical whole-body PET/CT scans of 13 melanoma patients were reconstructed according to three scan protocols: the institution's original lesion detection protocol, EARL protocol, and Q.Clear protocol. VOIs were placed in lesions and healthy tissues according to the PERCIST criteria, SUV was normalized for lean body mass (LBM). SUVs were compared among the reconstruction protocols and variability was assessed. Anova with post-hoc Bonferroni correction was performed to detect differences between lesion SUVs among the different reconstruction protocols. **Results:** Mean (SD) liver SUV was 1.73 (0.27), 1.80 (0.32), and 1.73 (0.27) for the clinical, EARL, and Q.Clear protocol respectively, yielding coefficients of variation (CV) of 16%, 18%, and 15% respectively. 24 lesions were assessed with a maximum of 5 lesions per patient and two lesions per organ. Mean SUV_{peak} (SD) was 2.2 (1.6), 1.7 (1.4), and 2.2 (1.6) for the clinical, EARL, and Q.Clear protocol respectively. Mean SUV_{max} (SD) was respectively 4.0 (2.6), 2.5 (1.7), and 4.6 (3.3). No significant differences were detected in lesion SUV_{peak} (p = 0.382). Significant differences were detected in lesion SUV_{max} (p = 0.018). Post-hoc tests demonstrated a significant difference of lesion SUV_{max} between the EARL and clinical protocol (p < 0.001) and between the EARL and Q.Clear protocol (p < 0.001). No significant difference was found between the clinical and Q.Clear protocol (p = 0.154). **Conclusion:** These preliminary data indicate that Q.Clear is a valid alternative in replacing the original lesion detection protocol and succeeds at harmonizing lesion detection and quantification.

Phantom and Patient Analysis of the Impact Of Q.Clear Regularization in Texture Indices

G. Reynés-Llompart[1], J. Robles-Barba[1], E. Llinares-Tello[1], P. C. Notta[1], I. Gil-Viciano[1], A. Sabaté-Llobera[1], J. L. Vercher-Conejero[1], N. Calvo[1], C. Gámez-Cenzano[1], J. M. Martí-Climent[2]; [1]PET Unit, Nuclear Medicine Department. IDI. Hospital Universitari de Bellvitge. IDIBELL, L'Hospitalet de Llobregat, SPAIN, [2]Nuclear Medicine Department, Clínica Universidad de Navarra, Pamplona, SPAIN.

Purpose: To study the impact of Q.Clear (a fully convergent, noise constrained BSRM iterative reconstruction algorithm)

on texture indices change. **Methods:** All acquisitions were performed on a Discovery IQ PET/CT. Phantom analysis was performed using a NEMA Body IEC phantom. All six spheres were filled with a ratio of 8:1 and an activity concentration of 5.4 kBq/mL, and were acquired during 350 s on a single bed. Moreover, 10 lesions were analyzed from 8 different patients, acquired using 2.7 MBq/kg and 2 min per bed. All images were reconstructed with β values (a noise regularization parameter) of 50 to 500 using 50 intervals. For all lesions and spheres, a VOI of 40% of the SUV_{max} was performed. For each VOI, volume, SUV_{max} and SUV_{mean} were recorded. Texture indices were obtained using a resampling of 64 values between 0 and 20 units of SUV, which corresponds to units of 0.3 SUV. From the co-occurrence matrix, the second order parameters of Homogeneity and Entropy were calculated. Long-Run Emphasis (LRE) and Short-Run Emphasis (SRE) were calculated from the Gray-Level Run Length Matrix. Low-Level Zone Emphasis (LGZE) and High-Level Zone Emphasis (HGZE) were calculated from the Gray-Level Zone Matrix. **Results:** SUV_{max} and SUV_{mean} decrease as the parameter β increases, being more pronounced as the size of the sphere decreases. If we consider the set of 6 spheres at a time, the behavior of the textures against the β parameter presents two patterns: on one side Homogeneity, LRE and LGZE and on the other, Entropy, SER and HGZE. As the β increase, the first three indices increase, whereas the last three indices decrease. On the analyzed lesions, the variations of SUV and texture indices follow the same patterns as the β increases. Despite this trend, some lesions present a singular different behavior, especially on SRE and LRE parameters, making the difference in texture indices very dependent on β. Only for HGZE and LGZE a convergence of the value is achieved around a beta of 300. From these trends, a general β to maximize the texture indices difference between lesions cannot be extracted. **Conclusion:** The Q.Clear algorithm acts by modifying the contrast of the lesions with the background, being able to abruptly modify the texture indices as a function of the parameter β, so it is an important parameter to standardize in case of multicenter studies.

EP-0019

Improving Quantitative Accuracy with use of High and Ultra-high Definition PET/CT Reconstruction

K. Binzel[1], J. Zhang[1], R. Moore[1], M. Friel[1], P. Maniawski[2], M. V. Knopp[1]; *[1]The Ohio State University, Columbus, OH, UNITED STATES OF AMERICA, [2]Philips Healthcare, Cleveland, OH, UNITED STATES OF AMERICA.*

Purpose/Introduction: Next-generation digital PET/CT provides improved count statistics and sensitivity making high and ultra-high definition image reconstruction feasible. Previous clinical evaluations have shown the improvement in visual quality and lesion detectability, this study assessed the improvement in quantitative accuracy via phantom validation. **Subjects & Methods:** A NEMA phantom with hollow sphere inserts was filled with ^{18}F with 2:1, 4:1, 8:1, 16:1, 32:1 and 64:1 activity concentration ratios. Data were acquired on a pre-com-

mercial release digital photon counting system (Philips Vereos) and reconstructed. Matrix sizes used for image reconstruction included a 144x144 matrix for standard definition (SD) 4x4x4 mm³ voxel lengths, 288x288 matrix for high definition (HD) 2x2x2 mm³ voxel lengths, and 576x576 matrix for ultra-high definition (UHD) 1x1x1 mm³ voxel lengths. For each matrix size, we additionally changed the number of iterative subsets from 1-35 in increments of 5. Activity concentrations and recovery coefficients (RC) were recorded for each image set. **Results:** HD and UHD images were found to be more quantitatively accurate than SD images. For the 1 and 0.5 mL spheres, the SD RCs were 0.84 and 0.57, respectively, when using 15 subsets. For the HD reconstructions, the RCs were 0.91 and 0.64. UHD images had RCs of 0.89 and 0.65. We found that for HD and UHD reconstruction, using a larger number of subsets degraded the image quality and also biased the RCs in the larger spheres to overestimate the true activity concentrations. Thus, we found that a lower number of subsets for HD and UHD reconstructions provided was preferable, findings consistent with review of clinical data sets. **Discussion/Conclusion:** Phantom validation of the improvement in quantitative accuracy with high and ultra-high definition imaging leads to greater confidence in using such reconstruction protocols for clinical data sets. The quantification in small hot objects is improved with HD and UHD imaging, while refining the number of subsets used in reconstruction prevents overestimation of activity concentrations of larger objects, where the activity is already accurately measured on SD imaging.

Assessment of different reconstruction parameters for quantification of FDG-PET brain imaging

T. C. G. Moalosi[1,2,3], P. Dupont[3,4], A. Ellmann[1,3], J. Warwick[1,3], A. Doruyter[1,3], M. Du Toit[2,3], M. Mix[1,5]; [1]Tygerberg Hospital (Nuclear Medicine), Cape Town, SOUTH AFRICA, [2]Tygerberg Hospital (Medical Physics), Cape Town, SOUTH AFRICA, [3]Stellenbosch University, Cape Town, SOUTH AFRICA, [4]KU Leuven, Leuven, BELGIUM, [5]University of Freiburg, Freiburg, GERMANY.

Introduction and Aim: Reconstruction influences quantitative results in PET imaging. The aim of this study was to evaluate different image reconstruction parameters and their impact on quantification of ^{18}F-FDG PET of the brain. The reconstruction parameters studied were the number of iterations, and the use of time of flight (TOF) information. In addition, we investigated the effect of scan duration on image quality. **Materials and Methods:** A Philips® Gemini TF Big bore PET/CT was used for acquiring data of a 3D Hoffman Brain phantom. Data were acquired for 25 minutes in list mode format after injection of 40 MBq FDG, and reconstructed with a voxel size of 2x2x2 mm³ using two different iterative reconstruction algorithms: LOR-RAMLA and BLOB-OS. The number of iterations and subsets was varied successively from 3/33 (vendor default) to 30/33, acquisition scan duration from 1 to 25 minutes, and TOF switched on and off for BLOB-OS. The impact on image quality was analyzed in 15 cortical and sub-

cortical brain regions (volumes of interest, VOIs) and for gray and white matter. **Results:** Contrast increased for all regions of the brain and for grey matter (GM) /white matter (WM) ratio as the number of iterations increased. Image convergence was reached after fifteen iterations for all the algorithms. The coefficient of variation (COV) for all VOIs showed BLOB-OS with TOF to be superior to the other algorithms. The COV results for different scan durations showed only a minimal improvement after 5 minutes in high-activity regions (GM), and after 10 minutes in low-activity regions (WM). **Discussion:** These results demonstrate that optimization of the vendor's default number of iterations is possible for brain imaging and that 15 iterations is more appropriate. Furthermore, a scan duration of 10 minutes is sufficient for brain imaging. Although it is often postulated that TOF information has no impact in brain imaging, our results show a small improvement. **Conclusion:** Based on phantom data ^{18}F-FDG brain imaging for 10 minutes and reconstructed with the BLOB-OS algorithm including TOF information with 15 iterations is optimal on the Philips Gemini TF Big bore PET/CT.

EP-0021

Accelerated 3D Detector Modelling using a Lookup-table based on GATE Simulations of a single Detector Block

H. Xu, J. Scheins, M. Lenz, C. Lerche, N. Shah; Forschungzentrum Juelich, Juelich, GERMANY.

Introduction: Accurate Detector Response Functions(DRF) increase the spatial resolution and SNR for Position emission tomography (PET) in iterative image reconstruction[1]. However, full-scale 3D modelling of pixelated crystal arrays (blocks) covering all possible γ rays still remains challenging. In this abstract, we demonstrate for the Siemens BrainPET system the advantageous usage of a lookup-table(LUT) generated from GATE[2] simulations, which holds DRF for a single detector block. In this way, the DRF for each crystal combination can be derived by fetching ray-dependent LUT weights. **Methods:** Any detector block of BrainPET consists of 12×12 LSO crystals (2.5×2.5 mm^2), which is irradiated in GATE with a plane source sampling the whole field-of-view(FOV). In order to characterize all possible incident γ rays in the reference coordinate system of the block(BC), four parameters are necessary, i. e., **(x, y, θ, φ)**, where **(x,y)** denotes the intersection point with the block front surface; **θ** is the polar angle; **φ** is the azimuth angle. Each parameter is sampled as defined in table 1 and a LUT for the DRF is created. All γ rays simulated in GATE need to be sorted according to the binning of table 1 and the DRF information (crystal ID and detected counts each) is stored as sparse vector. The LUT can be used to calculate the detection probability for any Line-of-Response(LOR) by combining two specific LUT rows which are addressed by the ray coordinates in BC of the two involved blocks. **Results and Conclusion:** GATE simulations have been performed with 279.6 GBq(0.2 MBq*1398000) γ rays totally, among which 7.56x10^9 have geometrical interactions with the block and 3.91x10^9 counts are detected. The obtained LUT size is found to be 1.5 GB. For the

simulation of detector data, we have compared GATE with our LUT approach using an off-center cylindrical phantom (10 MBq activity) along axial direction. The pure calculation time for GATE and our program are 1218s and 1038s respectively (14.8% speed up). The measured counts for both are 566170 and 527498 (6.8% less due to loss of block crosstalk). However, the sinogram patterns in transaxial plane remain similar with some shadowing effects when it comes to the edge of FOV. In conclusion, the LUT method for detector simulations works properly and is feasible to provide similar results as full GATE simulations. Reference: [1] Rahmim A, et al. Medical physics, 2013, 40(6). [2] Jan S, et al. Physics in medicine and biology, 2004, 49(19):4543.

EP-0022

Sub-centimeter lesion detectability in Point-spread function (PSF) and Time of flight (TOF) reconstructed PET images

I. Shiri[1], P. Ghafarian[2,3], A. Bitarafan-Rajabi[1], M. AY[4,5]; [1]Department of Medical Physics, School of Medicine, Iran University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF, [2]Chronic Respiratory Diseases Research Center, National Research Institute of Tuberculosis and Lung Diseases (NRITLD), Shahid Beheshti University of Medical Sciences, tehran, IRAN, ISLAMIC REPUBLIC OF, [3]PET/CT and Cyclotron Center, Masih Daneshvari Hospital, Shahid Beheshti University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF, [4]Research Center for Molecular and Cellular Imaging, Tehran University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF, [5]Department of Medical Physics, School of Medicine, Tehran University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF.

Aim: Small lesion detection at early stages of disease is very important for staging and therapy performance in cancer patients. Recently, advancements in hardware and software (Time-of-Flight and Point Spread Function) have facilitated the possibility of enabling sub-centimeter lesion detectability. The main purpose of this study was to investigate small lesion detectability for PSF and TOF reconstruction. **Material and Methods:** All measurements were performed on a GE Discovery 690 PET/CT scanner using a NEMA-IEC body phantom with six spheres (having diameters of 4, 5, 6, 7, 10 and 13mm) that were filled with 2:1 as well as 4:1 contrasts and different background activities. Images were reconstructed using the 3D-OSEM algorithm with and without TOF and PSF information, and involving different post-reconstruction filters. Lesion detectability was estimated both visually by a human observer and quantitatively using the lesion over background variation (LOBV) metric which was defined according to the Rose Model of statistical detection. **Result:** In the case of 2:1 contrast, the 13 mm hot sphere could be recognized in all reconstructed PET images, and for images reconstructed with TOF the 10 mm hot sphere could also be observed. When acquisition was made with 4:1 contrast, lower limit of detectability reached 6 mm and 5 mm diameters for OSEM+PSF and OSEM+PSF+TOF respectively. Quantitative

analysis of LOBV as function of FWHM of post reconstruction filter showed stronger filter (higher smoothing) caused an improvement in LOBV of lesions 13mm in diameter. Conversely, the LOBV value trend in lesions smaller than 10mm in diameter was inverse, and deteriorated with increasing FWHM. When reconstruction was made with TOF, LOBV values was higher than without TOF information in both SBRs. **Conclusion:** TOF and PSF reconstruction improve sub-centimeter lesion detectability. Our study encourage the utilization of next generation PET technology (TOF and PSF reconstruction) in clinical PET systems which lead to substantially improvement of sub-centimeter lesion detectability

EP-0023

Impact of matrix size on metabolic tumor volume (MTV) and total lesion glycolysis (TLG) in PSF-based PET image

I. Shiri[1], A. Rahmim[2,3], S. Ashrafinia[3], P. Geramifar[4], A. Bitarafan-Rajabi[1,5]; [1]Department of Medical Physics, School of Medicine, Iran University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF, [2]Department of Radiology, Johns Hopkins University, Baltimore, MD, UNITED STATES OF AMERICA, [3]Department of Electrical and Computer Engineering, Johns Hopkins University, Baltimore, MD, UNITED STATES OF AMERICA, [4]Research Center for Nuclear Medicine, Shariati Hospital, Tehran University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF, [5]Cardiovascular Intervention Research Center, Rajaie Cardiovascular Medical and Research Center, Iran University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF.

Aim: Volume-based parameters such as MTV and total lesion glycolysis (TLG=MTV×SUV_{mean}) are potentially valuable imaging biomarkers in the evaluation of response to therapy and prognostication in cancer patients. The objective of the present study was to investigate the impact of matrix size on MTV and TLG as delineated from whole-body PET images. **Material and methods:** Twenty-six patient were included in this study. PET images were reconstructed using the 3D-OSEM algorithm with and without PSF modeling, with 2 iterations, 21 subsets, 4mm FWHM of Gaussian post-reconstruction filter and different matrix sizes (128×128, 168×168, 256×256, 336×336). Twenty-nine lesions were segmented using an automatic fuzzy locally adaptive Bayesian (FLAB) method. From these segmented lesions, metabolic tumor volume and TLG were calculated. **Result:** Values of MTV and TLG were significantly higher for PSF-based reconstruction at the same matrix size. The deviations in MTV and TLG, relative to clinical standard reconstruction (3D-OSEM-168), were significantly different, depending on matrix size. At higher matrix sizes, the SUVmean was overestimated while MTV and TLG were underestimated relative to 3D-OSEM-168. **Conclusion:** These findings demonstrate the dependency of volume-based parameters (MTV, TLG) on reconstruction algorithm and matrix size. Higher matrix sizes in PET imaging may improve image quality, but do alter quantification parameters such as MTV and TLG, and their accuracy must be considered, especially in treatment response assessment.

Quantification of 177-Lu and 131-I: a phantom study

J. Kupferschlaeger, H. Dittmann, S. Poth, C. la Fougère; University Hospital Tuebingen/ Nuclear medicine, Tuebingen, GERMANY.

Aim: Absolute quantification is a necessary condition for the dosimetry of radionuclide treatments with 131-I and 177-Lu. Aim of this study was to investigate the accuracy of quantification, the determination of recovery coefficients (RC) for partial volume correction (PVC), the influence of CT high voltage (HV) and tube current on quantification, the influence of dead time and a comparison of planar and tomographic sensitivity. **Material and Methods:** For both isotopes we used the IEC-Phantom with hot-sphere and lung insert as well as the Anthropomorphic Torso Phantom (ATP) with lung, liver and 2 spherical inserts inside the liver. All measurements were performed on a Discovery 670 NM/CT PRO® (GE) SPECT/CT system. For each measurement we acquired CTs with different HV- and tube-current settings. Five energy windows were used in case of 177-Lu to extract the low energy (EM1:114 keV) and high energy emissions (EM2:208 keV). Dead time was determined by using vials with decaying activities over a period of 8 weeks. Quantification was done using the Q.Metrix® software (GE) with OSEM reconstruction including scatter-, CT-based attenuation correction and resolution recovery. VOI were defined for the spheres, the liver, the phantom and liver background and the cold lung inserts. For each VOI we recorded average and maximum activity concentration in Bq/ml. **Results:** CT HV and tube current has minor influence on quantification: maximum deviation is less than 2% from the activity concentrations using a reference CT for attenuation correction. The total activity in both phantoms and in the liver insert could be reproduced with a maximum error of 10% for 177-Lu(EM2) and 131-I whereas 20% for 177-Lu(EM1). RC for small lesions were always underestimated (< 0.8) in case of 131-I. RC were constant (~1) for lesion volumes larger 5 ml for 177-Lu(EM2). 177-Lu(EM1) reconstructions reveal smaller RC compared to 177-Lu(Em2). Scatter correction underestimates the scatter fraction: 20% to 50% of the background activity concentration was found in the cold lung inserts. Dead time correction is negligible in case of 177-Lu (count loss < 7% under treatment conditions) whereas dead time correction for 131-I should be considered during treatment (12% count loss for 250 MBq in the FOV). **Conclusions/Discussion:** Absolute quantification of SPECT data using the Q.Metrix® software is possible if all corrections are applied. This is valid for large structures like organs but PVC should be applied for quantification of small lesions. Further improvement of scatter correction is needed.

EP-0025

The quantitative SPECT/CT scoring of MIBG cardiac scintigraphy to identify patients with Lewy body diseases

S. Matsuo[1], H. Wakabayashi[1], K. Nakajima[1], K. Okuda[2], H. Yoneyama[1], S. Kinuya[1]; [1]Kanazawa University, Kanazawa, JAPAN, [2]Kanazawa Medical University, Kanazawa, JAPAN.

The heart-to-mediastinum ratio (HMR) of iodine-123-metaiodobenzylguanidine (MIBG) has been used to determine the uptake of the heart to evaluate sympathetic nerve activity. However quantitative SPECT scoring is still uncommon because of the inferior attenuation artifact is often found in MIBG SPECT image. Therefore we performed SPECT/CT-attenuation correction using IQ-SPECT/CT (Symbia T6, Siemens) in a short-term acquisition protocol. We investigated the relationship between quantitative SPECT/CT scoring and HMR using IQ-SPECT and conventional collimator. Furthermore we aimed to determine the SPECT scoring as well as HMR to identify Lewy body diseases (LBD). Subjects The subjects include 253 patients who underwent MIBG imaging. IQ-SPECT was used to identify LBD, including Parkinson's disease and dementia with LBD. The early- and delayed-phase cardiac images were obtained. HMR was calculated by the ratio of mean counts between heart and mediastinum areas of interest drawn on a planar image by means of automated software analysis. SPECT images were obtained by IQ-SPECT system with CT-attenuation correction. The disorders were assessed by QPS (Cedars-Sinai Medical Center, Los Angels, CA) quantitatively, using the standard 17-segment and 5-point scoring system. A neurologist expert determined the final clinical diagnosis by using international clinical diagnostic criteria. Results IQ-SPECT completed the acquisition of SPECT imaging in about 5 minutes (n=28). In part, conventional SPECT took 16 minutes (n=225). Interior decreased uptake was significantly improved by CT-attenuation correction using IQ-SPECT/CT. The quantitative QPS scoring showed significantly close relationships with HMR values (P<0.0001). The quantitative QPS scoring showed significantly close relationships with HMR values (p<0.0001). IQ-SPECT in a short time acquisition protocol was applied to the patients with dementia. SPECT scoring with IQ-SPECT identified LBD subjects (49±4 vs 4±3, p<0.0001). HMR in LBD was significantly decreased than that of non-LBD (1.4±0.2 vs 3.2±0.6, p<0.0001). Conventional collimator showed close relationship between SPECT scoring and HMR (p<0.0001). Conclusion SPECT scoring was feasible and inferior attenuation was improved. Quantitative SPECT scoring with IQ-SPECT/CT using short acquisition protocol might be feasible. Quantitative MIBG SPECT scoring might be a possible biomarker of evaluating severity of cardiac sympathetic nerve dysfunction to identify patients with Lewy body diseases.

EP-0026

Relationship between image and clinical indices in the differential diagnosis of dementia using ^{18}F-FDG-PET images and machine learning

M. Sakata[1], X. Wang[1,2], K. Ishii[1], Y. Kimura[1,3], K. Wagatsuma[1], K. Ishibashi[1], J. Toyohara[1], N. Yata[2], Y. Manabe[2]; [1]Tokyo Metropolitan Institute of Gerontology, Tokyo, JAPAN, [2]Chiba University, Chiba, JAPAN, [3]Kindai University, Kinokawa, JAPAN.

Objectives: Differential diagnosis of dementia type, such as Alzheimer's disease (AD), fronto-temporal dementia (FTD), and dementia with Lewy bodies (DLB), is necessary for treatment and care of patients with dementia. We present an automatic classification based on brain ^{18}F-FDG-PET images to support the diagnosis using the support vector machine (SVM) and propose a novel image index for assessing the severity or progression of dementia. **Methods:** We used ^{18}F-FDG-PET images from four groups: normal healthy elderly individuals (NL; n = 60; 66 ± 10 years), patients with AD (n = 64; 71 ± 10 years), with FTD (n = 23; 76 ± 8 years), and with DLB (n = 12; 61 ± 10 years). The images were anatomically normalized using parameters from the normalizations of individual T1-weighted MR images using DARTEL (Ashburner, 2007). SVM feature values were extracted from 116 VOIs using the automated anatomical labeling cortical parcellation map (Tzourio-Mazoyer, 2002) and were normalized with the cerebral global mean. The four-class classification of SVM is composed of a combination of two-class classification. We propose the signed distance from the border of the two-class classification between each group with dementia and NL (e.g. AD-NL model) as an image index for assessing the severity or progression of dementia. In the present study, precision of the four-class classification was verified using the leave-one-out cross-validation method. Furthermore, for the data (NL, n = 60, 120 scans; AD, n = 40, 79 scans; and FTD, n = 12, 23 scans) comprising the mini mental state examination (MMSE) score, the correlations between the proposed image index and MMSE score was investigated in the AD-NL and FTD-NL model. Data of each subject gathered at different times were included in these correlations. **Results:** The precision of the four-class classification was 92% , 81%, 61%, and 50% in the NL, AD, FTD and DLB groups, respectively. An imbalance in the sample size and pathological heterogeneities may have caused inadequate accuracies in the FTD and DLB groups. The correlation between the proposed image index and MMSE score was significant (p < 0.001, Spearman's rank correlation) in both the AD-NL model and FTD-NL models. The correlation coefficient in the FTD-NL model (0.27) was lower than that in the AD-NL model (0.72). **Conclusions:** The automatic classification using SMV is capable of supporting the differential diagnosis of dementia, and the proposed image index can help in assessing the severity or progression of dementia.

EP-0027

Noninvasive quantitation of rat cerebral blood flow using ^{99m}Tc-HMPAO without arterial blood sampling

C. Suzuki, M. Kosugi, Y. Magata; Hamamatsu University School of Medicine, Hamamatsu, JAPAN.

Purpose: Cerebral blood flow (CBF) assessment in small animals meaningfully enhances the understanding of pathology in model animals and facilitates evaluation of drug efficacy. We previously reported that rat CBF values is calculated dividing the brain radioactivity concentration (C_{Brain}) at 5 min post-injection of ^{99m}Tc-HMPAO by the integrated arterial blood radioactivity concentration until 19 s post-injection of ^{99m}Tc-HMPAO

(AUC_{Blood}). However, this CBF assessment procedure can not be repeated in the same animals, since arterial blood sampling is needed. In the present study, we established noninvasive quantitation of rat CBF using ^{99m}Tc-HMPAO without arterial blood sampling. **Subjects & Methods:** Acetazolamide (0, 25, or 50 mg/kg) treated rats were intravenously administered with ^{99m}Tc-HMPAO. Arterial blood sampling and chest dynamic planar imaging using single-pinhole collimator were performed for 1 min just after ^{99m}Tc-HMPAO administration. Head SPECT imaging using multi-pinhole collimator was performed from 15 to 57 min post-injection of ^{99m}Tc-HMPAO, and then brain was resected. Radioactivity in arterial blood was measured with the auto-well γ counter and integrated blood radioactivity concentration until 19 s post-injection of ^{99m}Tc-HMPAO (AUC_{Blood}**-sampling**) was calculated using the trapezoidal approximation. Radioactivity in resected brain was measured with the auto-well γ counter and radioactivity concentration in brain (C_{Brain}**-resection**) was calculated. The region of interest (ROI) was manually drawn over heart-blood pool on planar images and integrated heart-blood pool radioactivity concentration until 19 s post-injection of ^{99m}Tc-HMPAO (AUC_{Blood}**-planar**) was calculated. The ROI was manually drawn over brain on SPECT images and radioactivity concentration in brain (C_{Brain}**-SPECT**) was quantified. The rat CBF values, which were noninvasively obtained using C_{Brain}**-SPECT** and AUC_{Blood}**-planar**, were compared with the CBF estimated by the conventional method using C_{Brain}**-resection** and AUC_{Blood}**- sampling**. **Results:** AUC_{Blood}**-planar** was identical to AUC_{Blood}**-sampling**. Since our previous study showed C_{Brain} was steady from 14 s to 60 min post-injection of ^{99m}Tc-HMPAO, C_{Brain}**-SPECT** and C_{Brain}**-resection** were determined between 14 s and 60 min post-injection. C_{Brain}**-SPECT** was identical to C_{Brain}**-resection**. Noninvasively calculated CBF using C_{Brain}**-SPECT** and AUC_{Blood}**-planar** was well correlated with conventionally estimated CBF using C_{Brain}**-resection** and AUC_{Blood}**- sampling** (Spearman's rank correlation coefficient = 0.918, $p < 0.001$). **Conclusion:** Rat CBF could be noninvasively quantitated using ^{99m}Tc-HMPAO chest dynamic planar imaging and head SPECT imaging.

Dosimetric survey on administered activity of 11C-CHOLINE in PET/CT examinations in Sardinia from 2012 to 2016: a retrospective analysis

A. Loi[1], S. Zucca[2], M. Carta[1], D. De Vittor[1], G. Melis[3], S. Loi[2]; [1]Alliance Medical, Cagliari, ITALY, [2]C. Fisica Sanitaria Azienda Ospedaliera G. Brotzu, Cagliari, ITALY, [3]S.C. Medicina nucleare e Centro PET Azienda Ospedaliera G. Brotzu Cagliari, Cagliari, ITALY.

Due to the radionuclide short half life, exams with 11C-Choline can be provided only in PET center with cyclotron. In Sardinia, only the site at the Azienda Ospedaliera Brotzu (AOB) in Cagliari at the moment performs 11C-Choline PET/CT. In this study a retrospective analysis of administrated activities from 2012 to 2016 were reported, together with an estimate of the effective dose imparted to patient. Local Diagnostic Reference Levels (LDRL) in PET/CT for 11C-CHOLINE for the region were suggested. **Materials and Methods:** All exams performed from 2012 to 2016 were included in this survey. Data collection has been carried out through routines of automation. For each examination, administered 11C-CHOLINE activity was registered together with patient weight, height and age. From 2012 to 2015 - a standard activity was administered independently of patient size and examinations were performed on a GE DST 2D scanner. At the end of 2015 a new scanner has been installed (GE DISCOVERY IQ), and the administered activity was calculated using a reference value of 4.0MBq/Kg. Starting from the administered activity, the absorbed dose was calculated with OLINDA/EXM version 1.0 software using Male standard phantom. To take into account the variability of patient size within patient cohort, for each patient, organ masses were linearly scaled with the ratio of patient weight and the standard phantom weight (73 kg). **Results:** A total of 1206 examinations were analyzed (224@2012; 238@2013; 245@2014; 219@2015; 280@2016); The average CHOLINE injected activity was 377±22 MBq in 2012-2015 (75° percentile 391 MBq), and decreased to 316±51 MBq on 2016, 75° percentile 340 MBq) in 2016. The effective doses calculated on 2012-2015 were 1.81±0.18 mSv for patients with a weight lower than 60 kg, 1.44±0.11 mSv for patients with a weight between 60 and 80 kg, and 1.11±0.12 mSv for patients with a weight bigger than 80 kg. The effective doses calculated on 2016 were significantly lower (up to 40% for light patients) and almost constant independently on patients size : 1.13±0.01 mSv for patients with a weight lower than 60 kg, 1.13±0.01 mSv for patient with a weight between 60 and 80 kg, and 1.18±0.04 mSv for patient with a weight bigger than 80 kg. **Conclusion:** The results of the dosimetric survey highlighted the impact of new scanner technology and the optimization of the administered activity on patient dose. Moreover, LDRL for the administered activity in 11C-CHOLINE PET/CT examinations have been derived.

EP-0029

Regional-wide survey on administered activity of 18F-FDG in PET/CT examinations in Sardinia

F. Pinna[1], S. Zucca[2], D. De Vittor[3], M. Carta[3], S. Loi[2], G. Melis[4], M. Giannoni[4], A. Spanu[5], P. Marini[1], A. Loi[3]; [1]S.S.D Fisica Sanitaria Azienda Ospedaliera Universitaria, Sassari, ITALY, [2]S.C. Fisica Sanitaria Azienda Ospedaliera G. Brotzu Cagliari, Cagliari, ITALY, [3]Alliance Medical, Cagliari, ITALY, [4]S.C. Medicina nucleare e Centro PET Azienda Ospedaliera G. Brotzu, Cagliari, ITALY, [5]S.C. Medicina Nucleare e Centro PET Azienda Ospedaliera Universitaria, Sassari, ITALY.

Diagnostic Reference Levels (DRL) are a QA tool introduced by ICRP in order to monitor practice and to promote improvements in patient protection. A regional-wide survey was conducted in Sardinia to estimate the administered activity of 18-FDG in PET/CT examinations. The results were analyzed to suggest Local Diagnostic Reference Levels (LDRL) in PET/CT on a regional basis. The analysis also includes the evaluation of inter-center variability. **Material and Method:** All the FDG PET/CT examinations performed in the three PET/CT center in Sardinia in 2016 were included in the survey (A: Siemens Biograph 40 installation year 2008; B: GE DISCOVERY 710 year 2013; C: GE DISCOV-

ERY IQ installation year 2016). Data collection has been carried out through routines of automation or user-developed code (Matlab@Matworks), extracting information recorded on di-com-header data. For each examination, administered 18-FDG activity was registered together with patient weight, height and age. In order to better estimate the influence of scanner technology and optimization of diagnostic procedure on administered activity, for center C, data collected in 2016 were retrospectively compared with those registered in 2015, when a standard activity was administered with a small modulation for patient size using an older scanner (GE DST 2D). Mann-Whitney statistical test with a significance level of 0.05 was performed to compare inter-center distributions. **Results:** A total of 4406 examinations were analyzed; 1554 (35.3%) performed on A, 1039 (23.6%) on B, and 1813 (41.1%) on C. No differences were found on patient's age and weight distributions among centers. The overall average 18F-FDG injected activities were 268±62 MBq and 3.94±0.40 MBq/kg (75 percentile 307 MBq and 4.23 MBq/kg). The administered activity was statistically different among center, with a mean value of 290±65 MBq (4.28±0.39 MBq/kg) for center A, 268±56 MBq (3.88±0.12 MBq/kg) for center B and 250±56 MBq (3.53±0.31 MBq/kg) for center C. In particular, for center C, data registered in 2016 were compared with those collected in 2015 (356±45 MBq and 5.44±1.10 MBq/kg, p<0.05). For each center, the correlation between patient's weight and injected activity is affected by a non-negligible residual error, depending on automatic dispensator dose systems. **Conclusion:** LDRL for the administered activity in 18-FDG PET/CT have been derived from the analysis of all examinations performed in Sardinia in 2016. Results highlighted a variability among centers, mainly due to different installed technology, that can be minimized by standardization and optimization of diagnostic procedures.

Plasma to blood ratio derived parent fractions for robust plasma input based kinetic analysis of dynamic ¹⁸F-FLT PET studies in NSCLC cancer patients

A. Avendaño-Estrada[1,2,3], G. Kramer[2], V. Frings[2], D. Vallez García[1], E. Smit[4], A. Lammertsma[2], O. Hoekstra[2], R. Boellaard[1,2], QuicConcept Consortium; [1]University Medical Center Groningen, Groningen, NETHERLANDS, [2]VU University Medical Center, Amsterdam, NETHERLANDS, [3]Universidad Nacional Autónoma de México, Mexico, MEXICO, [4]The Netherlands Cancer Institute, Amsterdam, NETHERLANDS.

Purpose/Introduction: Full quantitative analysis of dynamic ¹⁸F-FLT PET studies is important to validate the use of simplified methods and metrics, such as SUVs, for early response assessment (1). However, full quantitative kinetic analysis requires the use of a metabolite corrected plasma input function. The measurement of parent fractions is often associated with poor signal to noise ratio, measurement errors and it is labor intensive. In the present work, we investigated if parent fractions could be estimated directly from plasma and blood activity concentrations thereby obviating the need to perform metabolite analysis and/

or use estimated values for quality control purposes. **Subjects & Methods:** Nine NSCLC patients underwent three 60 min dynamic ¹⁸F-FLT PET scans: at baseline within 7 days before treatment and at 7 and 28 days after start of the treatment. During each PET study 6 to 7 venous blood samples were collected to obtain blood and plasma concentrations as well as parent fractions. These data were subsequently used in combination with an image derived input function to generate a metabolite corrected input function. A plasma input reversible 2-tissue compartment model (PMOD v3.7) was applied to the tumor time activity curves, yielding tumor VTs. This analysis was repeated using parent fractions calculated from plasma to blood ratios using an equation derived from the baseline scans only. VTs derived from analysis using measured and calculated parent fractions were compared as well as longitudinal % changes in VT using both approaches. Agreement was assessed with linear regression, interclass correlation coefficients (ICC) and Bland-Altman plots. **Results:** Excellent agreement between VTs derived from measured vs calculated parent fractions was found for both early (R2=0.983[0.981-0.996 (95%CI)]; ICC=0.992[0.982-0.996]) and late response (R2=0.994[0.992-0.998]; ICC=0.996[0.991-0.998] scans. Furthermore, Bland-Altman plots showed a strong agreement for both early (percentage bias=0.284[-6.172-6.741]) and late response (percentage bias=-1.165[-7.125-4.795] studies. **Discussion/Conclusion:** The strong agreement in tumor ¹⁸F-FLT VTs as well as their longitudinal changes when obtained from input functions using measured or calculated parent fractions suggest that parent fractions can be reliably estimated using plasma to blood ratios. Plasma to blood ratio derived parent fractions could be used as an alternative when blood sample data are noisy or incomplete, to discard outliers, or when it is not possible to acquire sufficient samples for metabolite analysis. The method may be applicable to other tracers as well, but this requires further studies. **Reference:** 1. Frings et al., JNM 2014

Importance of algorithms in SUV calculation. Quantitative comparison of differences in SUV obtained from OSEM and Q.Clear® algorithms.Our experience

M. Agolti[1], B. Moglia[2], J. Biurrun Manresa, 3100[3], J. Bustos[2]; [1]Clinica Modelo, Parana, ARGENTINA, [2]Fundación Centro de Medicina Nuclear y Molecular Entre Ríos (CEMENER), Oro Verde, ARGENTINA, [3]Centro de Investigaciones y Transferencia de Entre Ríos (CITER) CONICET-UNER, Oro Verde, ARGENTINA.

Purpose: the standardized uptake value (SUV) is an objective measurement of FDG uptake, which is important in the evaluation of response to treatment. Using a new reconstruction algorithm (Q.Clear®), we noticed large differences in the resulting SUV values compared to the conventional OSEM algorithm. In this study we quantified these differences in order to assess their potential impact on treatment evaluation. **Subjects and Methods:** 72 FDG PET-CT scans performed with a GE Discovery PET/CT 710 were included in the study, performed in our center between December 2016 and April 2017. Scans were assessed simultaneously using the same ROI size at the same location.

Maximum SUV from both algorithms were obtained from the liver as a control (n=72), from lesions of 1 cm (n=28) and from lesions of 2 cm (n=28). Data was analyzed using Bland-Altman analysis, from which the mean difference and the 95% limits of agreement (LoA) were derived. The mean difference is a measure of systematic error, and the LoA represent the maximum differences due to random error between methods, within which 95% of the differences between measurements are expected to lie. Differences were calculated as ($SUV_{Q.Clear}$ - SUV_{OSEM}). **Results:** In average, $SUV_{Q.Clear}$ was larger than SUV_{OSEM}, but not in all individual cases. Mean differences in normal liver SUV were 0.1%, and the maximum differences ranged between -5.2% and 5.4%. Mean differences in SUV from 1 cm lesions were 7.5%, and the maximum differences ranged between -19.9% and 35.0%. Finally, mean differences in SUV from 2 cm lesions were 3.5%, and the maximum differences ranged between -6.0% and 13.0%. **Conclusion:** the differences between methods were acceptable for liver SUVs, but not for SUVs quantified from lesions. Differences were larger for smaller lesions, and the large systematic error (up to 7.5%) and random variation found (up to 35%) are clinically significant, since they could erroneously lead to a change in treatment for some patients. Therefore, SUVs obtained from different algorithms cannot be used interchangeably. These results stress the importance of visual assessment to evaluate response to treatment, since SUV is neither silly nor smart, but is rather a Simple Useful Value that has to be considered within the proper clinical context.

A quantitative functional and structural multiple sclerosis analysis A 99mTcECD brain SPECT study with statistical parametric mapping SPM evaluation and voxel based morphometry VBM analysis of brain MRI using CAT12 toolbox

N. Chabi[1], R. Nemati[2], M. Assadi[2]; [1]Division of Biomedical Engineering (BME), The Persian Gulf Nuclear Medicine Research Center, Bushehr University of Medical Sciences,, Bushehr, IRAN, ISLAMIC REPUBLIC OF, [2]Division of Neuroscience, The Persian Gulf Nuclear Medicine Research Center, Bushehr University of Medical Sciences,, Bushehr, IRAN, ISLAMIC REPUBLIC OF.

Introduction: This study performed a visual and quantitative analysis on secondary progressive multiple sclerosis SP-MS patients' functional and structural data. In detail, we assessed regional cerebral blood flow in SP-MS patients using statistical parametric mapping (SPM) to detect hypo perfused area on 99mTc-ECD SPECT as well as voxel based morphometry analysis of gray matter (GM) on volumetric T1-MRI scan. **Subjects and Methods:** Both MRI and SPECT were performed on 5 SP-MS patients and 20 age-matched healthy volunteers. Using statistical parametric mapping, 5 SPECT images from patients with SP-MS were compared with a control group of 20 subjects using a statistical threshold of p<0.05 (corrected for multiple comparisons). On the other hand, global GM loss has been reported in multiple sclerosis. Therefore, we want to find the regions with significantly reduced GM density. By using CAT12 software, VBM analysis

was applied to MRI data of participants. Segmented GM volumes were compared on a voxel-by-voxel basis to find regions with GM loss (P < 0.05, corrected for multiple comparisons). **Results:** All the quantitative results obtained by SPM and VBM analysis were compared with visual analyses by a nuclear physician and neurologist. Findings reveal that SPM result and nuclear physician decision, VBM result and neurologist decision were in a good agreement. Furthermore, SPM analysis of SPECT data provides information that is in complement to structural analysis of MRI. In detail, based on SPM analysis of SPECT, hyper perfusion area was seen in WM and hypo perfusion area in GM. **Conclusion:** brain perfusion SPECT can be a complementary tool to other diagnostic modalities such as MRI and clinical examinations in disease surveillance and monitoring. SPM analysis of brain SPECT and VBM analysis of MRI will provide complementary information for physicians. **Keywords**: secondary progressive multiple sclerosis SP-MS patients, 99mTc-ECD brain perfusion single photon emission computed tomography (SPECT), Magnetic Resonance Imaging (MRI), Statistical Parametric Mapping (SPM), Voxel Based Morphometry (VBM), Computational Anatomy Toolbox (CAT12), Gray matter (GM), White Matter (WM)

EP-0033

Prediction of chemotherapy response in osteosarcoma using multi-parametric PET/MRI texture feature

*Y. Park, W. Kim, B. Byun, J. Kang, C. Kong, W. Song, I. Lim, Y. Lee, B. Kim, S. Lim, **S. Woo**; Korea Institute of Radiological and Medical Sciences, Seoul, KOREA, REPUBLIC OF.*

Objectives: Intra-tumor heterogeneity assessment can improve patient management and prognosis. The aim of this study was to improve the predictability of chemotherapy response in osteosarcoma using combined information with metabolic and anatomical heterogeneity. **Methods:** Tumor heterogeneity was assessed using texture analysis and subject were a cohort of 22 patients with osteosarcoma who underwent baseline PET and MRI from May 2010 to September 2013. PET/MRI image was acquired using PET/CT (Biograph 6 PET/CT scanner, Siemens, Malvern, PA) and 3.0T MRI (MAGNETOM Trio A Tim, Siemens, Germany). Difference volume of interest (VOI) define method base on PET image can affect the prediction sensitivity, we performed the texture analysis using two difference VOI region which is PET and MRI. The F-18 FDG PET image was visualized metabolic heterogeneity through the standard uptake value (SUV) and PET VOI was defined by region growing. MRI of T2 weighted image was visualized anatomical heterogeneity through the pixel intensity and T2 VOI was defined by manually drawing. To enhance the predictability of chemotherapy response, we assessed multi-parametric texture feature. Multi-parametric texture features were extracted using T2 VOI from F-18 FDG PET and T2 weighted MRI images of global, local, and regional area. The response of chemotherapy and statistical significance of texture feature were estimated using receiver operating characteristic (ROC) and logistic regression. Results: Tumor region was identified by region growing PET VOI and manual T2 VOI. The PET VOI and MRI VOI sensitivity on F-18 FDG PET image was

61.78% and 91.86%, respectively. The chemotherapy response of PET texture features with T2 VOI has more sensitive than PET region growing VOI texture features. Logistic regression analysis of PET and MRI texture features with T2 VOI was *p* = 0.08 and *p* = 0.05, respectively. Multi-parametric texture feature logistic regression with metabolic and anatomical heterogeneity was *p* = 0.046. **Conclusions:** Prediction ability using multi-parametric texture feature which is extracted in PET/MRI was more sensitive and accurately than single parameter texture features. PET/MR multi-parametric texture features are expected to be the useful method prediction of chemotherapy response in osteosarcoma patients.

EP-0034

An efficient software tool for measuring the total metabolic tumor volume in whole body PET

C. Nioche[1], A. Cotterau[2], M. Meignan[3], I. Buvat[1]; [1]Service Hospitalier Frédéric Joliot, Imiv, Cea, Inserm, Cnrs, Univ. Paris-sud, Université Paris Saclay, CEA-SHFJ, Orsay, Orsay, FRANCE, [2]Médecine Nucléaire, Lysa Im, Hôpital Tenon et Hôpitaux Universitaires Henri Mondor, Paris, Paris, FRANCE, [3]Lysa Im, Hôpitaux Universitaires Henri Mondor, Créteil, Créteil, FRANCE.

Objectives: The total metabolic tumor volume (TMTV) estimated from FDG-PET images is a promising biomarker of the total tumor burden, especially in patients with lymphomas. However, estimating TMTV is challenging and often time consuming when multiple targets, including primary tumors, nodes and metastases, with various metabolic activities, volumes and contrasts have to be segmented. We developed a convenient and user-friendly pipeline for estimating TMTV that is now offered as part of the free LIFEx software (www.lifexsoft.org). Methods: The procedure of TMTV calculation is based on four customizable steps: The first step is a semiautomatic initialization of intermediate to high metabolic activity (typically SUV>2) volumes in which the tumor regions should be identified, yielding a possibly disconnected gross volume GV. Then, tumor volume delineation within this initial GV is refined using one or several customizable criteria in combination, including: 1) absolute SUV threshold (ie SUV>2.5), 2) region-to-liver activity threshold, 3) percent SUV-max threshold (ie, 40%), 4) adaptive threshold accounting for surrounding activity. A third step identifies groups of connected voxels, deletes clusters that are too small in volumes, and derives the resulting TMTV. Last, a final step makes it possible for the user to remove regions with physiological uptake (brain, bladder, etc) using a 1-click operation, or to add regions using a 1-click operation that runs a region growing algorithm. The TMTV value is automatically updated during these operations. All regions can be displayed using axial, sagittal and coronal slices and using a maximum-intensity-projection representation. PET volume and associated regions can also be overlapped with the CT or MR for visual analysis. The whole procedure has been implemented in the LIFEx free software (Windows, MacOS and Linux compatible) thus enabling textural indices calculation from each component of the TMTV. The results are exported in an Excel file and in the form of an image booklet displaying the regions. All regions included in the final TMTV volumes can be saved on disk for subsequent use. Results: The intuitive software interface as well as associated demo videos allow for immediate use of the tool. The calculation of TMTV is performed within 4 minutes from a whole body PET scan. Being easily accessible, the software has already been downloaded by more than 250 users over the world and is currently under evaluation to assess its ability to produce fast and robust estimates of TMTV in the context of multicenter studies of lymphoma patient cohorts.
